LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

INTRODUCTORY LECTURE.

GENTLEMEN,—If we compare the two kingdoms of nature, the organized and the mineral, we can scarcely fail being struck with one very remarkable distinction—namely, that the first has what may be called two modes of existence, the one termed *health*, which I shall take the liberty of designating the *normal* condition; the other denominated *disease*, which, by way of contrast, we may regard as an *abnormal* state. Each of these conditions has a science appropriated to itself; physiology treats of organized beings in the healthy state, while pathology is devoted to the condition of disease. Among minerals, however, we find no existence analogous to that of disease, nor any science corresponding to that of pathology; their active properties never vary either in degree or kind, and therefore their phenomena can be anticipated and calculated. Among living beings, on the other hand, we find, as the illustrious Bichat has remarked, that the functions are subject to numberless varieties, frequently exceeding their natural degree, and baffling all calculation. We cannot foresee or foretell their phenomena: we judge only by analogy, which in the vast proportion of instances is extremely uncertain.

The existence of all living beings, whether we regard them in their normal or their abnormal states, is limited; and therefore death is common to both conditions—"*Fugienda nunquam est mors.*" But as the latter of these two states, namely disease, has a tendency to shorten this limited existence, and as it is generally accompanied with more or less pain, we almost instinctively seek some means of restoring health, and thereby of preserving our lives, and alleviating our sufferings. These means, whatever may be their nature, have been denominated *remedies*, or therapeutic agents; and that branch of the science of medicine which treats of them has been called *acology*.

They include those which may be denominated *hygienic*, as aliment, bodily exercise, mental impressions, and other agents, which were formerly very absurdly termed the non-naturals; 2dly, *surgical* remedies, as bloodletting, acupuncture, &c. 3dly, certain *physical* agents, as heat and electricity; and 4thly, *pharmacological* agents, or *medicines*, and which we may define to be those substances used in the treatment of diseases, which, when applied to the body, produce certain alterations or modifications in the functions, and which are not essentially alimentary.

The present course of lectures is devoted to the last class, and will contain an account of the natural history, the physical and chemical properties, and the physiological effects and uses, of medicines. I should prefer announcing the course simply as one on *Pharmacology*; but, in conformity with the regulations of the examining boards, I am obliged to employ the term *Materia Medica*, which is so far objectionable, that writers are not agreed on its limits, its uses, or its applications.

History.—It is customary to devote a portion of the introductory lecture to an historical outline. I may remark, however, that in the short space of a single lecture it is impossible to offer more than a very rudimentary sketch. I am of opinion also, that it is much better, and far more interesting, to study the history of a science when we have made ourselves acquainted with most of its details; so that, in fact,

any historical discussion would be more appropriate at the conclusion than at the commencement of a course.

With this impression I have thought it best to put a few of the leading particulars relating to pharmacology into a tabular form, to which each of you can refer at your leisure. [See p. 10.]

In justice I ought to add, that I have received considerable assistance in the arrangement of this table from Dr. Choulant's *Tafeln zur Geschichte der Medizin.* Those who desire to enter more fully into the subject may consult the posthumous work of Dr. Voigtels, entitled, *Vollständiges System der Arzneimittellehre*, and also Dr. Bischoff's *Handbuch der Arzneimittellehre.* We are remarkably deficient in writings in our language on this subject; and, indeed, the only book to which I can refer you, is the *Treatise of Materia Medica*, by Dr. Cullen, in which you will find a brief critical survey of the history of this branch of medical science. As pharmacology forms a part of the science of medicine, you may refer with advantage to writings on the history of medicine in general. Sprengel's work on this subject is the most elaborate and complete yet published. As an introduction, I would strongly recommend to your notice the admirable *Sketch of the History of Medicine*, by Dr. Bostock.

Means of learning the effects of medicines.—Leaving, therefore, historical details, I proceed to examine the different means we may adopt to acquire a knowledge of the effects of medicines. I may premise, that the statements made by the ancient writers on this subject are not to be relied on, for in some cases they are totally devoid of truth, and in others much overcharged. This is particularly remarkable in the writings of Dioscorides and Galen.

The doctrines of *astral influences*, and of *signatures*, adopted by Paracelsus, are too absurd to require much notice. They form part of a supposed hidden science of divine mysteries, called *cabala*. On account of their resemblance to the testicles, the bulbs of some orchideous plants were supposed to act on the organs of generation; while the fancied resemblance between the leaves of the *Pulmonaria* and the lungs of man was thought to indicate the the use of this plant in pulmonary affections.

Discarding all absurd notions of this kind, we have *four* principal methods which in modern times have been resorted to, for the purpose of ascertaining the effects of medicines. These are founded—

1. On the sensible properties of medicines.
2. On their natural historical properties.
3. On their chemical properties.
4. On the experience of their effects.

1. The *sensible properties*, such as colour, taste, and smell, have long been used. We are, in fact, led instinctively to this mode of investigation. The lower animals evidently derive considerable assistance in judging of the qualities of their food by the organs of their senses. We find them for the most part avoiding poisonous substances, selecting such as are wholesome and nutritious, and when sick, frequently resorting to such herbs as are best adapted to assist in restoring health.

There are two important objections to this mode of estimating the properties of medicines: the first is the difficulty, if not absolute impossibility, of defining sensations; for supposing a new substance should be discovered, whose taste is remarkable and peculiar, how is it possible to convey by words to a second person a correct notion of the kind of impression made on the gustatory organ? Secondly, the idiosyncrasies of sensation are so extraordinary, that two persons may disagree as to the character of the sensible property; for a sensation which may be grateful and pleasing to one, may be disagreeable and loathsome to another.

This mode of judging of the virtues of medicines has been confined principally to vegetable substances; but even here cannot be relied on. Both *Quinia* and *Strychnia* are devoid of smell, are white, and have an intensely bitter taste, and yet, notwithstanding this agreement in their sensible properties, differ widely in their effects, the one being a tonic, the other a powerful poison.

2. *Natural-historical properties* are those made use of in natural history to determine the affinities of natural bodies; they comprehend exterior form, and structure. They have been resorted to for the purpose of determining the effects of certain substances. It has long been supposed that those plants which resemble each other in their external appearances are endowed with analogous medicinal properties. Cæsalpinus was, I believe, the first who taught this doctrine. Baptista Porta says, "*tali formæ tales vires conveniunt*;" and Linnæus also remarks, "*Plantæ quæ genere conveniunt, etiam virtute conveniunt; quæ ordine naturali continentur, etiam virtute propius accedunt; quæque* classe *naturali congruunt, etiam viribus quodammodo congruunt.*" The first distinct work on the subject is that by Decandolle, entitled, *Essai sur les Propriétés Médicales des Plantes*, the first edition of which appeared in 1804. In the year 1831 we had another interesting treatise on the same subject by Dierbach, entitled, *Abhandlung über die Arzneikräfte des Planzen, verglichen mit ihrer Structur und ihren chemischen Bestandtheilen.*

It is undeniable that in numerous instances there exists an analogy between

the exterior forms and the medicinal properties of plants, so that we can sometimes predict the active principle and mode of operation, merely by knowing to what part of a natural arrangement a plant properly belongs. Cruciferæ (fig. 1), for exam-

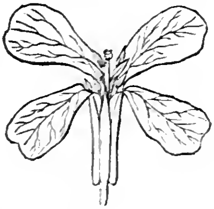

FIG. 1.—*Raphanus sativus.*

ple, present the greatest uniformity in their botanical, chemical, and medicinal characters. They contain a volatile acrid principle, which renders them stimulant; and having been employed successfully in scurvy, are frequently termed anti-scorbutics. The Labiatæ (fig. 2),

FIG. 2.—*Glechoma hederacea.*

which constitute, perhaps, the most natural family of the whole vegetable kingdom, contain a bitter resinous, or extractive matter, and an etherial, aromatic, or volatile oil; which two principles, mixed in different proportions, are found in all the species, to which they communicate tonic and carminative properties. Neither Cruciferæ nor Labiatæ contain a single unwholesome or even suspicious species. In Coniferæ (fig. 3) we find the different species per-

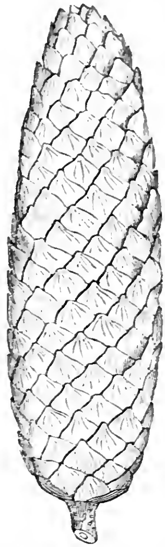

FIG. 3.—*Picea vulgaris.*

vaded with an oleo-resinous juice, in consequence of which they possess stimulant properties.

We are obliged, however, to admit the existence of numerous exceptions to the before-mentioned general rule. We can point out many families, the plants of which appear to possess the greatest botanical affinity for each other, but whose remedial properties are very different. Take Umbelliferæ (fig. 4) as an example. The root and leaves of the *Daucus carota* are wholesome and nutritive, but the analogous parts of *Conium maculatum* are highly poisonous. In some cases we even find plants of the

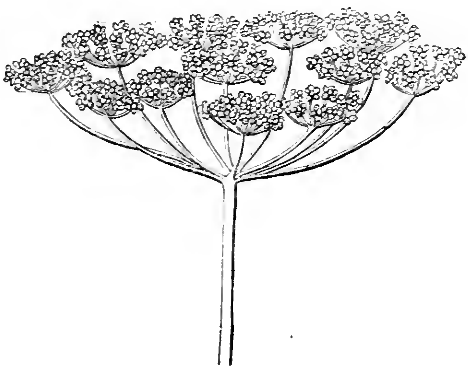

FIG. 4.—*Fœniculum vulgare.*

same genus differing considerably from each other in a medicinal point of view. I need only mention as examples in proof, *Cucumis melo* and *Cucumis colocynthis.* If

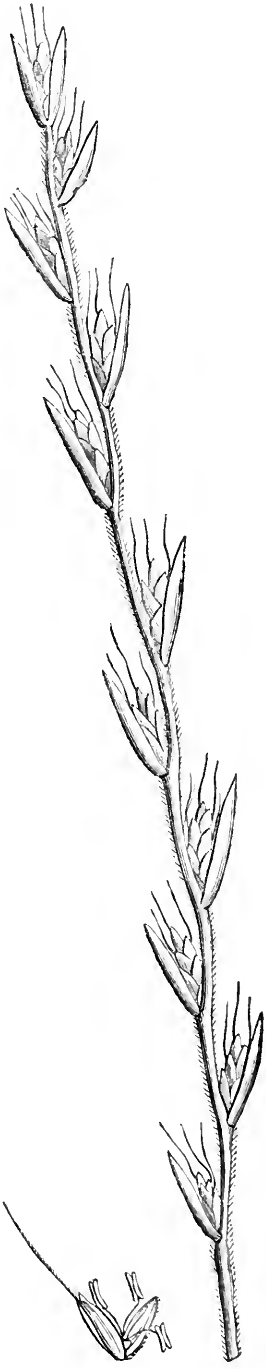

Fig. 5.—*Lolium temulentum.*

we are to believe the statements of competent authorities, even Gramineæ, which Decandolle declares to be "la famille la plus naturelle," contains more than one exception to the general statement in question. For the most part the plants of this family are farinaceous and nutritive. "None," says Dr. Lindley, "are unwholesome in their natural state, with the single exception of *Lolium temulentum* (fig. 5), a common weed in many parts of England, the effects of which are undoubtedly deleterious, although perhaps much exaggerated." I may remark, however, that several other grasses have been asserted to be unwholesome. Loudon tells us that the seeds of *Bromus mollis* are said to bring on giddiness in the human species and quadrupeds, and to be fatal to poultry. The root of *Bromus purgans* is said to be used in Canada as an emetic, in doses of forty grains; but I confess the authority for this statement is somewhat doubtful. *Bromus catharticus*, a Chilian plant, has a thick root, which acts as a purgative. I am aware that these statements require further proof, for *Bromus secalinus*, which was stated by some writers also to be poisonous, has been found by Cordier to be innocuous. We have, however, another case, on much better authority (that of Humboldt);—I allude now to a Peruvian grass, called by Kunth the *Festuca quadridentata* (fig. 6), and which is denominated in Sprengel's *Species Plantarum* the *Sessleria quitensis*. Humboldt tells us that this plant is very poisonous, and even fatal to animals. Perhaps this may be the grass described by some under the name of *Carapoucha*, and which, by others, has been called *Carapullo*. Frezier, in his *Voyage to the South Sea and along the Coasts of Chili and Peru*, in the years 1712, 1713, and 1714, says, in speaking of Lima, "There is an herb called *Carapullo*, which grows like a tuft of grass, and yields an ear, the decoction of which makes such as drink it delirious for some days. The Indians make use of it to discover the natural disposition of their children. All the time when it has its operation, they place by them the tools of all such trades as they may follow,—as by a maiden, a spindle, wool, scissars, cloth, kitchen furniture, &c.; and by a youth, accoutrements for a horse, awls, hammers, &c.: and that tool they take most fancy to in their delirium, is a certain indication of the trade they are fittest for,—as I was assured by a French surgeon, who was an eye-witness of this verity."

In the family *Solaneæ* we meet with other exceptions. Compare, for example, the fruits of *Capsicum annuum* and *Atropa Belladonnæ*. I might select many other instances (especially from the family *Leguminosæ*), to the same effect, but I shall content myself with the examples already

Fig. 6.—*Festuca quadridentata.*

adduced, as sufficiently warranting the assertion that, in the present state of science, botanical affinities cannot be confidently relied on by the medical practitioner for determining the effects of remedial agents. I cannot, therefore, agree with Dr. Lindley, in his assertion, that "a knowledge of one plant is a guide to the practitioner, which enables him to substitute some other plant *with confidence* which is naturally allied to it." In drawing this conclusion, I must caution you against running into an opposite extreme, and assuming that botanical affinities are of no use whatever to the medical practitioner. It will be my duty, when I speak of the vegetable materia medica, to shew you that as a *general rule* we may admit that plants of the same family agree in the *nature* of their medicinal operation, but that this general rule has many remarkable exceptions which diminish its utility in practice, though they do not absolutely destroy it. Doubtless in some

cases the apparent exceptions arise from our imperfect knowledge of the affinities of plants.

No one has even attempted to infer the medicinal properties either of minerals or of animals from their natural-historical qualities. In the mineral kingdom, it has of late been shewn that two different substances may assume the same form; and that this depends not on a similarity in the *nature* but of the *number* of the molecules entering into the constitution of the substances. Such substances are said to be *isomorphous*. This fact proves that there is no necessary relation between the exterior forms and medicinal properties of minerals.

3. The *chemical properties* of medicines have sometimes been resorted to for the purpose of determining their medicinal properties. That this mode of investigation is fallacious, is, I think, demonstrated from the following circumstances:—

(*a*). Substances whose chemical properties are exceedingly dissimilar, sometimes concur in the nature of their medicinal effects; and as examples of this, I may mention manna and supertartrate of potash.

(*b*). Similarity of chemical properties is not always attended with a similarity of medicinal effect. *Baryta* and *Strontia*, for example, agree in so many chemical characters, that they were at first confounded; yet the salts of the first of these substances are energetic poisons, while those of the latter act feebly on the body.

(*c*). We cannot determine the operation of medicines by knowing either the nature or number of the ultimate particles. Who could have anticipated that a compound of carbon, nitrogen, and hydrogen (all inert substances) could possess such an energetic operation as that of *hydrocyanic acid?* *Carbonic* and *oxalic* acids are composed of the same kind of constituents the one as the other, but in somewhat different proportions; yet in how opposite a manner do these substances act when taken into the stomach! Compare the per centage composition of *Quinia*, *Strychnia*, and *Morphia*, and the slight differences in composition will not be found sufficient to explain their dissimilar operation.

	Quinia.	Morphia.	Strychnia.
Carbon ..	75·76	72·20	77·21
Hydrogen .	7·52	6·24	6·73
Nitrogen ..	8·11	4·92	5·96
Oxygen ..	8·61	16·66	10·10
	100·00	100·02	100·00

(*d*). But it may be said we ought to take proximate and not ultimate principles as our guide. To this I reply, we cannot always determine what are *products* and what *educts*, in our analysis of organic substances, and therefore we cannot tell precisely what are and what are not proximate principles. It was at one time supposed that the essential oil of bitter almonds was contained in the seeds from whence it is obtained. It is now well established that this oil, as well as the hydrocyanic acid it contains, are formed by the action of the water (employed in the process) on the almond cake. The same statement may be applied to the volatile oil of mustard-seed. If, then, this really happen in two cases, we may fairly suspect it in many others. Raspail regards the vegetable alkalies (such as quinia, cinchonia, morphia, &c.) as artificial products; but the balance of evidence is certainly against this notion.

(*e*). In some instances the active principle of a medicine is much more difficult to isolate than to discover the nature of the operation of the agent by other means. Ergot of rye is a good example of this. We have yet no satisfactory results from chemical investigations as to the nature and properties of the active principle of this substance.

(*f*). Lastly, it appears that two substances may be composed of the same constituents, and in the same ratio, and yet be endowed with different properties. Such substances are said to be *isomeric*.

4. *Experiment on man and other animals* constitutes the last and most important method of ascertaining the virtues of medicines; for I think I have made it sufficiently evident that for this purpose we cannot implicitly confide in the sensible, natural-historical, or chemical properties. The action of medicines and poisons on man is for the most part similar in kind or quality, though different in degree, to that on other animals,—modified somewhat by the variations in the development of the several organs and functions. It has been asserted that some substances which are energetic poisons to man are innocuous to animals, and *vice versâ*. Let me caution you against implicitly believing vague assertions of this kind. Thus Voigtels states that horses may eat *Aconitum napellus* with impunity; but Viborg has shewn that they, like man, are poisoned by it, though the quantity requisite to produce death is large. It is a popular notion that arsenious acid is innocuous to horses. I am told that doses of a scruple, or even half a drachm, are frequently exhibited to them, with no evidently hurtful consequences; nay, it is said with beneficial re-

sults. But notwithstanding these statements, we are quite certain that arsenious acid acts as a poison to the horse. In the year 1812, a man of the name of Dawson was indicted for poisoning several horses at Newmarket, by injecting an arsenical solution with a syringe into the watering-troughs. Mr. Bowles, a veterinary surgeon, in his evidence, mentioned that he had poisoned horses by way of experiment, and had found, after death, extensive inflammation of the stomach and intestines. The prisoner was condemned, and executed.

Let me not be misunderstood. I do not deny the diversity of action of poisons and medicines on different animals, but I decidedly agree in opinion with Dr. Christison, that "if the subject is studied more deeply, the greater number of the alleged diversities will prove rather apparent than real."

One objection to experiment on animals as a means of learning the operation of medicines, is that we can obtain little or no information respecting the peculiar influence which certain substances exercise in particular diseases. The beneficial effects of cinchona bark in agues could hardly have been discovered by comparative experiments, though the reverse has been asserted, as I shall hereafter notice.

A very important circumstance to bear in mind, in experiments on any animals, is that the effects of the same medicine vary with the part of the body to which it may be applied; for example, carbonic acid acts as a deadly poison when introduced into the lungs, whereas, taken into the stomach, it operates as an agreeable excitant. The volatile stimulants act more powerfully on the system when taken into the stomach, than when applied to the rectum.

In ascertaining the operation of remedial agents on man, it is necessary that we examine their influence in the two modes of existence—health and disease. A reliance on either solely may lead to most erroneous inferences. The beneficial influence of arsenious acid in agues, or in lepra, could never have been anticipated by any experiments made with this substance in health; nor could we form a correct notion of the effects and proper doses of opium by employing it in tetanus, nor by using mercurials in fever.

Thus, then, it appears, that although we may draw some general inferences as to the operation of medicines by the examination of their sensible, natural-historical, or chemical properties, yet the information thus gained is not sufficiently precise to be of much practical utility; and we are therefore necessitated to resort to careful observation of the effects on man and other animals, in order to arrive at accurate conclusions.

Cause of the effects of medicines.—Before I proceed to examine the nature of the effects produced by the action of medicines on the body, I think it expedient to bring before you some theoretical, or perhaps I ought to call them hypothetical, details, connected with our subject. Linnæus adopts as a canon a remark of Hoffman, that "*Duo in medicina fulcra sunt, ratio et experientia; experientia præcedit, ratio sequitur; hinc rationes in rebus medicis experientia non conditæ, nihil valent.*" I feel that I may be charged with inverting the order of proceeding inculcated in this sentence, by commencing my examination of the operation of pharmacological agents with subjects purely speculative. I feel also that this charge is so much the more valid, inasmuch as the hypothetical details in question lead to no practical results. But I would remark, that while, in framing general laws, it is essential we should be previously well conversant with particulars, yet it is not a necessary consequence that the same order should be followed in teaching; nay, in some instances such a mode of proceeding would be attended with manifest inconvenience. Thus, in explaining the law of universal gravitation, few persons would think it requisite to follow Newton through all those elaborate calculations by which he arrived at this general principle.

But it may be said, if a subject lead to no practical result, why discuss it? To this I cannot do better than reply in the language of Dr. Thomas Brown, in his work on the Philosophy of the Human Mind:—"To know well what hypotheses truly are in themselves, and what it is which they contribute to the explanation of phenomena, is, I am convinced, the surest of all preservatives against that too ready assent which you might otherwise be disposed to give them."

I am sure all of you will feel interested in the inquiry into the cause of those changes in the vital actions of the system produced by the agency of medicines. To what primary qualities are we to refer the vesicating property of cantharides, for example? This kind of discussion necessarily resolves itself into two parts—first, an examination of the agent (the medicine) producing the changes; and secondly, an inquiry into the nature and properties of the being in which these changes may be or are produced.

1. *Active force of Medicines.*—Medicines give rise to certain alterations in the system, which we denominate their *effects*; and we say, therefore, these agents are en-

dowed with an *active force.* But in what primary quality does this force reside? Some have directed their attention to the intimate structure, others to the chemical composition of medicines; thinking by these means to discover the cause of those changes produced on the living body by the agency of medicines. "I doubt not," says Locke, "but if we could discover the figure, size, texture, and motion of the minute constituent parts of any two bodies, we should know, without trial, several of their operations one upon another, as we do now the properties of the square or a triangle. Did we know the mechanical affections of the particles of rhubarb, hemlock, opium, and a man, as a watchmaker does those of a watch, whereby it performs its operations, and of a file, which, by rubbing on them, will alter the figure of any of the wheels, we should be able to tell before-hand that rhubarb will purge, hemlock kill, and opium make a man sleep." These mechanical notions of Locke harmonized well with those of the iatromechanical or iatromathematical sect of the age in which he lived: a sect which ranked amongst its supporters Borelli (its founder), Bellini, and others, in Italy; Sauvages, in France; and Pitcairn, Keill, Mead, and Freind, in England. They explained the functions of the body, the production of diseases, and the operation of medicines, on mechanical principles. The action of stimulants, for example, was supposed to depend on the pointed and needle-like form of their particles, and the operation of emollients on their globular form. I need hardly say, the existence of particles with the peculiar shapes assumed, is quite imaginary; and, indeed, if, for the sake of argument, we assume their existence, the action of medicines is, notwithstanding, quite inexplicable. We can, indeed, easily fancy that a ball of glass may be swallowed with impunity, and that the same substance, reduced to the form of a coarse powder, might cause considerable irritation by the mechanical action of the angular particles on the tender alimentary tube; but we cannot, on this hypothesis, explain why one medicine acts on one part of the body, and a second on another part. Quicksilver, tin-filings, and the hairs of the pod of the *Mucuna pruriens*, are still indeed employed, on account of their mechanical influence on the body. In the passage just quoted from Locke there are, in fact, two errors: first, the assumption that all the changes which take place in the external world are reducible to mechanical affections; and secondly, the presumption that we should be able to predict, without experience, the changes which would take place, supposing the assumption just mentioned were correct. A moment's reflection will satisfy us that, without experience, we should never have been able to predict occurrences far simpler than those just alluded to.

Chemical properties have been by some supposed to be those primary qualities to which we ought to refer the changes produced by medicines in the condition of the living body. At one time, indeed, it was thought that all the operations of the animal machine were dependent on chemical action. Diseases, for example, were supposed to depend on the too acid or too alkaline condition of the fluids, and medicines were presumed to act by neutralizing the one or the other of these states. Sylvius may be considered as the founder of the iatrochemical sect, while our countryman Willis may be regarded as one of its leading advocates. Although this sect has long since disappeared, among the revolutions to which medicine has always been subject, yet a modified trace of it may still be observed in the opinions of those writers who assert that to chemical properties we ought to refer the activity of medicinal substances. Barbier—one of the most respectable of French pharmacological writers, though one, I think, whose theoretical views frequently lead him to regard facts through a distorting medium — considers the active force of a medicine as consisting in a tendency which the particles of the latter have to unite with the constituents of the organized tissues. So that when a medicine is applied to the living body, its component parts endeavour to combine with the organic matter, the vital properties resist, and a new action is set up, which constitutes what we call the medicinal *effects*.

I would remark on this hypothesis, that some of our remedial means are undoubtedly to be regarded as chemical agents—for example, the caustics, properly so called; and it will be admitted, I think, that the influence possessed by alkalies and acids, in modifying the condition of the urine, is referable, in part at least, to their chemical peculiarities. In some other cases also, circumstances lead us to suspect the same kind of influence; thus we find, for the most part, that if we increase the affinity of a medicine for other agents, we frequently increase its influence over the body, and *vice versâ*. Thus the oxides of the metals are more active than the regulus, while sulphate of potash is much less active than either of its constituents.

Let us not, however, be led away by loose analogies. It is quite impossible, I

think, to admit that medicines generally are to be regarded as chemical agents. The few cases in which we have distinct evidence of a chemical operation are insufficient data on which to found a general law. Will any one be hardy enough to assert that the influence of hydrocyanic acid, or of opium, on the animal body, is of a chemical nature?

If, then, the greater number of our articles of the materia medica act, as far as we have evidence, neither by their mechanical nor by their chemical properties, to what other qualities are we to refer their operation? This question, gentlemen, is one which, in the present state of our knowledge, we are incompetent to answer. Considering the immense number of inorganic changes dependent on the agency of the electric fluid—taking into account also the wonderful relationship between electrical and vital phenomena, and the fondness of medical men for hypothesis—you will not be surprised to find that some have attempted an electrical theory of the operation of medicines. The instantaneous death caused by the application of concentrated hydrocyanic acid to certain parts of the body, is something like an electrical phenomenon.

2. *Vital properties.*—"Medicamenta non agunt in cadaver," is an axiom to which all persons will assent; and our inquiries immediately lead us to investigate the properties of living beings by which medicines are enabled to exercise their peculiar and remarkable influence. These properties or qualities are neither physical nor chemical: we denominate them vital or living: they are, therefore, essential to every organized or living part. Let me here caution you against confounding the terms *property* and *function*: the latter is the product of a peculiar organ or apparatus of organs, while the former is common to all living parts. Two vital properties have been usually described—the one called *sensibility*, the other *contractility*: by the first is meant the property or capability of receiving impressions, and by the latter, the capability of contracting or dilating—that is, of executing certain movements when the requisite impression has been made. A bean, for example, it is said, must possess both these qualities; for the act of growth is a proof that there exists internal movements; and these may be regarded as evidences of the reception of an impression of heat and moisture, without which germination cannot be effected.

But if the subject be a little more accurately examined, we shall find these supposed two vital properties are reducible to one. When a part feels an impression, it changes its mode of existence—that is to say, some kind of movement is effected in the part, which we can refer neither to physical nor chemical agencies. So that to assert a part possesses sensibility, is to express the capability of the part to act in a certain manner on the application of certain substances. Writers have in some instances described four, even five, vital properties. Bichat, for example, admits five; but three of these are evidently functions;—I mean perceptive sensibility, and the two kinds of sensible contractility (voluntary and involuntary). They are evidently performed by a distinct apparatus.

Whether we admit one or five, you will naturally inquire what agent confers this one, or these five, properties on organized beings? To this question no answer can be rendered. By one class of writers the phenomena of life have been ascribed to organic structure, just as the sounds of a musical instrument are referred to the mechanical arrangement of its parts; by another class it has been assumed that there exists a living internal principle (some have compared it to the electrical fluid), distinct from the body, and which is the cause of the organization. To enter into any discussion on these hypotheses would be out of place in a course of lectures like the present. I may refer such as are desirous of pursuing the inquiry to Dr. Barclay's work on Life and Organization.

The ultimate cause, then, of the operation of medicines (as well as of all other vital phenomena) is involved in impenetrable mystery. We know when a medicine is applied to the body it occasions some molecular movements to take place therein which are not sensible to us, and are only recognisable by their effects. But the cause and the nature of these motions are perfectly unknown. Let us turn this deficiency of knowledge to account; let it serve as a stimulus to our further inquiries. We ought, perhaps, as a celebrated German physiologist has observed, rather to be thankful that we have something yet to learn—something yet to obtain: for possession only makes us quiet, indolent, and proud. "If," says this writer, "the Deity held in his right hand all truth, and in his left only the ever-active impulse, the fond desire, and longing after truth, coupled with the condition of constantly erring, and should offer me the choice, I should humbly turn towards the left, and say, 'Father, give me this; pure truth is fit for thee alone!'"

[*Historical Table, &c.*

HISTORICAL TABLE OF MATERIA MEDICA.

BEFORE CHRIST. Chronology doubtful.	**EGYPTIAN MEDICINE.** First practised by Priests.—A temple erected to the Squill plant, under the name of *Crommyon* (Κρομμυον); Lapis ætites (a native oxide of iron); Fumigations with *Cyphi* (Κυφι), a mixture of 16 drugs; Slime of Nile; Nitrum (Carbonate of Soda?); Plasters and Unguents; Dietetical means. **HINDU MEDICINE.** Regimen; Unguents; Cataplasms; Fumigations; Baths. **HEBREW MEDICINE.** Hygiene; Cataplasms; Ablutions, &c.
To 430 B.C.	**GREEK MEDICINE.** BEFORE HIPPOCRATES.—1398 B.C. Melampus cured Madness by Hellebore, and Impotence by Iron Wine. 1270, Chiron the Centaur (*Chironea Centaureum*). 1263, Esculapius: his sons Machaon and Podilirius; the latter used Bloodletting. Hecate, Circe, and Medea, (Enchantresses), acquainted with poisonous plants. Aconite; Moly (Allium?); Nepenthes (Opium?). Asclepiadeæ, descendants of Esculapius. Mineral waters; Hemlock; Elaterium(?); Scammony; Euphorbium; Cnidia coccus (Daphne Gnidium?); Colocynth, &c. Silphium (Asafœtida?) discovered by Aristæus, 617. 580—500, Pythagoras: employed Magic, Dietetics, Mustard, Aniseed, Vinegar of Squills, &c.
From 430 B.C. to 150 AFTER CHRIST.	HIPPOCRATES. 460— (?) B.C. Hippocrates of Cos, the founder of Scientific Medicine. Employed Hygienic means (Diet, Baths, Exercise, &c.); Venesection and Cupping; Malva, Linum, Glycyrrhiza, Mel, Cera, Rosa, Gallæ, Punica granatum, Allium, Scilla, Veratrum, Helleborus, Staphisagria, Sinapis, Elaterium(?), Scammonia, Daphne, Ruta, Κανθαρις (Mylabris Cichorii?), Piper, Cardamomum, Cinnamomum, Cassia, Mentha, Anisum, Coriandrum, Cuminum, Anethum, Ammoniacum, Sagapenum, Galbanum, Silphium (Asafœtida?), Pix, Juniper, Styrax, Mastiches, Myrrha, Castoreum, Crocus, Conium, Hyoscyamus, Opium, Sulphur, Nitrum, Alumen, Sal commune, Cerussa, Acetas Cupri, Ferrum, Arsenicum, &c. ANCIENT DOGMATIC SCHOOL. 308 B.C. Founded by Thessalus and Draco (sons of Hippocrates) in conjunction with Polybius. NATURAL HISTORIANS. 350 B.C. Diocles of Carystus, Ριζοτομικα. 384—322 B.C. Aristotle on Animals (also Plants and Pharmacy). 371 to 286, Theophrastus of Eresus, founder of Botany. ALEXANDRIAN SCHOOL. 300 B.C. Medicine separated into Dietetics, Pharmacy, and Surgery. 295, Herophilus of Chalcedony employed Compound Medicines. 293, Erasistratus of Cos rejected Bloodletting: Simple Medicines. EMPIRIC SECT. 286 B.C. Founded by Philinus of Cos. 240, Serapion of Alexandria. Heraclides of Tarentum (the "Prince of Empirics.") Attalus. 138, Nicander, (Θηρ]ακα and Αλεξιφαρμακα). 135, Mithridates. METHODIC SECT. 100, B.C. Asclepiades of Bithynia: 60, his pupil Themison founder of the sect. All medicines Astringents or Relaxants. 54 A.D. (?) Pedacius Dioscorides, the most celebrated of the old writers on Materia Medica. Date uncertain. **ITALIANS.** 23 A.D. Menecrates; employed Escharotics; Diachylon Plaster. 50, Celsus (from 13 to 55.) Nourishing Glysters; Frictions with Oil. 70. Pliny, the Natural Historian; died 79. 230, Cœlius Aurelianus.
From 150 A.D. to 700 A.D.	GALEN TO THE FALL OF THE GREEK SCHOOL. 131—200 A.D. Claudius Galen, born at Pergamus. Diseases produced by alterations of the Humours, or πνευμα. Medicines act by their elementary qualities (heat, cold, dryness, moisture,) of each of which there are four degrees. This doctrine was held for 1400 years. 360 A.D. Oribasius. 550, Ætius: Camphor, Musk, &c. 560, Alexander of Tralles: Rhubarb, mild Laxatives. 650, Paulus Egineta.

AFTER CHRIST.	CHRISTIANS.	ARABIANS.
From 700 A.D. to 1100 A.D.	SCHOOL OF SALERNUM. Founded by Benedictine Monks: became celebrated about the eighth century. 1087, Constantine the African died. 1100, John of Milan (" Regimen Sanitatis Salerni.") 1110, Nicolus Præpositus. Diplomas granted. 1140, Matthew Plauter.	Doctrines of Galen. Mild Laxatives (Manna, Tamarinds, Senna, Rhubarb, Cassia) in place of Drastics. Chemical Medicines. Syrups, Juleps, Conserves, Loochs, Robs. Schools of Nisapour, Bagdad, Damascus, and Cordova. 702 A.D. Geber, the patriarch of Chemistry. 852 to 932, Rhazes. 865, Mesue the Elder. 880, Alkendi. 978 to 1036, Avicenna: for many centuries regarded as infallible. 1002, Serapion the Younger. 1017, Mesue the Younger.
From 1100 A.D. to 1500 A.D.	DARK AGES. Medicine practised by Monks, who mixed superstition, magic, and astrology, with the grossest imposition. 1215, Gilbert: Acetate Ammonia; Oil of Tartar per deliquium; Bath Waters. 1193—1282, Albertus Magnus. 1260, John of St. Amand. 1214—1284, Roger Bacon. 1240—1313, Arnold of Villa Nova. 1235—1315, Raymond Lully. 1317, Matthew Sylvaticus. 1343, Dondis (father and son). J. Platear. St. Ardouin: Hydrarg. Oxyd. Rub. 1394, Basil Valentine: Prepared Chemical Medicines; introduced Antimonials, Preparations of Lead, Ammonia, &c. 1407, Mercurial Fumigations. 1508, Guaiacum. 1518, Mercury internally. 1545, Rad. Chinæ. PARACELSUS. 1493—1541. Doctrine of Signatures. Overturned Galenism. Used Chemical Medicines; formed Tinctures, Essences, and Extracts.

HYDRIODATE OF POTASS IN ASCITES.

To the Editor of the Medical Gazette.

SIR,

I BEG leave to transmit to you the following case, as it illustrates well the happy effects of hydriodate of potass in ascites, depending upon hepatic derangement. Should you conceive it worthy a place in your valuable journal, you will oblige, sir,

Your obedient servant,

J. G. CUMMING,
M.R.C.S.E.

98, High-Street, Edinburgh,
Sept. 17, 1835.

Mrs. L., aged 56, of a delicate nervous habit of body, has for the last three or four weeks past felt her clothes getting gradually tight, from swelling of the abdomen, which swelling increased very rapidly the two days previous to that on which I saw her. I found the abdomen very perceptibly swollen, as if she had been seven or eight months pregnant; she complained of erratic pains passing through it; her legs were anasarcous; her bowels costive; her breathing frequent and interrupted; the pulse 120, open and compressible; and the urine dark, sparing, and voided with uneasiness. She mentions having experienced severe dyspeptic symptoms—diarrhœa, alternating with constipation, and considerable pain and uneasiness in the right hypochondrium, previous to the accession of the tumefaction, at which time she was conscious of having exposed herself to cold.

5th August.—I ordered

℞ Pulv. Jalap. C. ℈i.; Submur. Hyd. gr. vi. M.; and Supertart. Potassæ, to be freely administered.

6th.—The medicines operated freely; the pulse 70; and the swelling of the limbs somewhat less. The supertart. potassæ was ordered to be continued, and the preceding powder to be taken, the half at bed-time, and the remaining half in the morning.

7th.—The limbs the same; the abdomen fully as tense. The powder answered better in divided doses, and was ordered to be repeated in the same manner.

8th.—No improvement. The following mixture ordered:—

℞ Lig. Quassiæ, ℈ij.; Rad. Gentianæ, ℈j.; Aquæ Ferventis, ℥xvj.; Macera per horam, et cola. Liq. colat. add, Hydriodatis Potassæ, gr. xxxvj.; Carbon. Potassæ, ℈ij. A table-spoonful in a glass of water three times a day.

By the use of this mixture she so rapidly improved that in six days the effusion seemed completely absorbed; in short, by the administration of a single repetition of this mixture, and purgative pills occasionally, she was completely and permanently cured.

NOTICE OF DR. EDWIN HARRISON'S

MODE OF DISTINGUISHING THE BOUNDARIES OF THE LUNGS, LIVER, &c.

BY INSPECTION OF THE CHEST.

By DR. C. J. B. WILLIAMS.

WITHIN the last few years the physical signs of diseases have been continually receiving additions from several zealous and intelligent pathologists, both at home and abroad; and although even with these new aids perhaps none of us will speak on these subjects with the confidence which characterizes the writings of the sagacious but too sanguine discoverer of auscultation, yet the general knowledge of physical diagnosis may be fairly said to be considerably more extended than it was in his time. But the very extent of this knowledge becomes in practice no small obstacle to its being attained or used. The multiplicity of matters requiring attention, and the care and time necessary to make a physical examination unequivocal or satisfactory, have thrown many an impatient student back on the general symptoms, uncertain and fallacious as they are now known to be. Any mode of abridging or facilitating examinations which are tedious to the patient and laborious and perplexing to the physician, is therefore especially worthy of attention; and if it should have no other than these advantages, they are sufficient to recommend the simple fact which has been lately pointed out to myself and others by Dr. Edwin Harrison, at St. George's Hospital, and which, as far as he knows, has never before been noticed.

When the naked chest is viewed in a

good light, certain depressions and elevations may be observed, especially at the lower lateral and anterior parts, which are independent of the inequalities of the ribs. These Dr. Harrison considers to indicate the general shape and position of the contained organs, and he expects (I think with reason) that the observation of them may be of material use in exploring diseases of the chest. Thus the prominence caused on the right side by the liver gives a pretty distinct representation of the parts of that organ that are in contact with the walls of the chest; and the depression or furrow, which is discernible above it, generally marks the commencement of the lungs. This depression does not accompany the line of the ribs, but where it happens in its course to run between two ribs, that intercostal space is deeper than others. Above this furrow percussion will give the resonance of the lung; below it, the dead sound of the liver; and the distinction is generally plain enough to the eye to enable us to point out, before hand, what will sound clear and what dull.

On the left side there are also inequalities, which in a general way indicate the position of the several subjacent viscera, but not, as far as I have been able to judge, so accurately as those on the right side.

I refrain at present from entering into further details, and from dilating on the physical and pathological bearings of these matters, both because I have yet had little experience of their applications, and because the chief object of this communication is to announce them to the profession as original observations of my friend Dr. Harrison, whose peculiar repugnance to authorship deters him from doing so himself. He is investigating the matter further, and liberally wishes that others may be enabled to do so likewise, that the true value of these facts may be speedily estimated.

Half-moon Street,
Sept. 23, 1835.

TEMPORARY TRANSPOSITION OF THE HEART.

To the Editor of the Medical Gazette.

Sir,

In your valuable journal of the 22d of August, a case was reported by M. Raiken, of Volterra, of the temporary transposition of the heart; and I beg to forward a similar case, which was admitted into the Middlesex Hospital the latter end of last summer.

I am, sir,
Your obedient servant,
Edward W. Tuson.

Sept. 23, 1835.

Robert Ashby, a boy, about 13 years of age, was admitted into the Middlesex Hospital, September 21, 1834, having been run over by one of the carts employed on the rail-road near the Hampstead Road, the wheels having passed over his chest from the left to the right side. Upon examining the boy, the ribs were found to be much bent and flattened on the left side, causing the right side of the chest to project very considerably; at the same time no fracture could be discovered. There was much difficulty in breathing, the pulse very irregular, and the heart's action could not be felt on the left side, but on placing the hand on the right side of the sternum, its pulsation could be very distinctly discovered. It appeared that the force of the wheels had bent the ribs, and propelled the heart to the right side of the thorax. It was considered almost impossible for the boy to survive. He was bled two or three times while at the hospital, and saline medicines, with squills, administered. A few days after his admission the metallic tinkling was very distinctly heard at the upper part of the right side of the chest, and this sound could be heard for about three weeks, during which period the boy gradually got better, and left the hospital, nearly well, on the 14th of October, at which time the action of the heart could be felt in its natural situation, and the shape of the thorax had resumed its natural appearance.

ACCOUNT OF THE CEPHALOTRIBE OF M. BAUDELOCQUE.

To the Editor of the Medical Gazette.

Sir,

As I have not met with any notice of an instrument which appears to be calculated to effect a great improvement in the obstetrical branch of the profession, I have been induced to send you the following description of it. Should you

deem it worthy of a place in your valuable journal, you will, by inserting it, much oblige, sir,

Your most obedient servant,

JOHN-CHAS. COOKE,

Member of the Royal College of Surgeons of Edinburgh, and Licentiate of the Society of Apothecaries of London.

Coventry, Sept. 22, 1835.

In 1819, M. Baudelocque, nephew of the celebrated accoucheur of that name, presented a memoir to the Royal Academy of Sciences, entitled, "Du broiement de la tête de l'enfant, mort dans le sein de sa mère; nouveau procédé pour terminer l'accouchement laborieux;" in which he described an instrument invented by him for crushing the head of the fœtus when dead, and in this manner reducing it to the smallest possible dimensions. Before entering upon the description of the instrument itself, which he terms the cephalotribe, he points out the cases in which he would have recourse to it.

When the pelvis is so distorted, or so small, as to render delivery by the natural passages altogether impossible by the aid of the ordinary instruments, and when the child is still living, he considers the Cæsarean operation to be necessary; but when, on the other hand, the fœtus is dead, he maintains that we ought to have recourse to the cephalotribe, and to discard the perforator and crotchet entirely. He admits the difficulty of obtaining an accurate admeasurement of the diameters of the pelvis, and also the want of certain signs of the death of the fœtus. It is obvious, however, that these objections apply as forcibly to the old mode of proceeding, by the perforator and crotchet, as to the use of M. Baudelocque's instrument.

When we have at once the certainty of the death of the fœtus, and the impossibility of accomplishing the delivery by the aid of the forceps alone, the majority of authors recommend us to open the cranium, and to empty it of its contents, in order to destroy the disproportion existing between the child's head and the dimensions of the pelvis. Now although this may be done without risk to the maternal structure, yet, as it in no way affects the base of the skull, we are obliged to use the crotchet in order to break it up, as it frequently offers a most serious impediment to the termination of the labour.

And here the freedom from danger ceases, as even with the greatest precaution on the part of the practitioner the uterus and vagina will often be lacerated to a formidable extent, in consequence of the instrument slipping from its hold.

It has been stated by Sir C. M. Clarke, that a living child cannot pass if the conjugate diameter of the pelvis be only $3\frac{1}{4}$ inches, and that even this will frequently require the use of the perforator. Now the distance between one zygoma and the other being commonly $3\frac{1}{2}$ inches, and in some instances 4 inches, it is clear that the perforator can be of no advantage in these cases, as the incompressible base of the cranium will be wider than the aperture through which it has to pass.

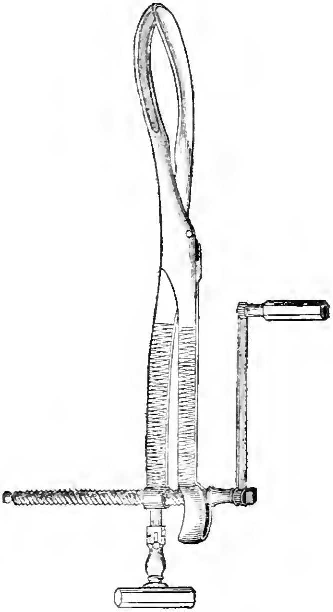
It is, then, the crotchet that M. Baudelocque proposes to supersede by the use of the cephalotribe.

In the report of MM. Boyer and Dumeril, who formed the commission appointed by the Academy to report on the value of the instrument, I find some observations on its weight, &c. These objections M. Baudelocque has obviated, by considerably reducing its size. The reporters conclude by saying, "L'invention de M. Baudelocque est une preuve de son zèle pour le perfectionnement de son art, et ce zèle nous parait digne d'éloges."

The cephalotribe consists, as the annexed sketch will show, of two blades, resembling in form Smellie's forceps, and locking in a similar manner. The blades have no fenestræ, are three lines thick, and but sixteen broad; so that M. Baudelocque has been able to introduce them into a pelvis the diameter of which was only twenty lines. Of course they would pass with facility when the diameter amounts to two inches. The length of the whole is sufficient to enable the operator to seize the head when placed above the brim. The curvature corresponds to that of the canal to be traversed.

The handles are an inch longer than the blades, as measured from the lock or axis of the instrument; they are five lines in thickness, and seven in breadth; they are each perforated at their extremities, to receive a screw six and a half inches long. To this screw a handle is attached, which measures six inches in length. The weight of the whole is about five and a half pounds, as manu-

factured by Sirhenry, of Paris. Probably, in the hands of an English cutler, its weight might be still farther reduced. The mode of introducing the blades corresponds in every respect with that usually observed in cases requiring the forceps. The head being firmly grasped, the handle is to be turned, when the cerebral mass is pressed out at the orbits, nares, ears, &c.; and the bones forming the base of the cranium are crushed by the compression exerted by the instrument. It is worthy of remark, that the scalp is never lacerated, and, consequently, no chance of injuring the uterus or vagina by the bones splintering exists.



I can myself bear testimony to the great physical power of the cephalotribe, as I have repeatedly seen the Professor crush the head of a full-grown fœtus, and in one instance that of a child a month old. In none of these instances was the scalp torn even in the smallest degree.

In a letter dated July 17, 1835, M. Baudelocque informs me that he has operated seven times, although he has published the details of five cases only. One of the unpublished cases occurred whilst I was in Paris, and an opportunity was afforded me of witnessing it. MM. Paul Dubois, Barbette ainé, and Rivallié, have operated four times; so that altogether there are eleven cases on record in which the cephalotribe has been used, and in all, I believe, with success. In all, too, the Cæsarean operation had been considered to be absolutely necessary, from the impossibility which existed of delivering by the crochet.

The details of these cases will be found in M. Baudelocque's "Mémoire sur le Cephalotripsie," and in the number for April, 1835, of the "Journal de Médecine," edited by M. Lucas-Championnière.

M. Baudelocque has invented other instruments and processes, which may form the subject of a future communication.

EXAMINATION OF PANIZZA'S OPINIONS

ON THE

FUNCTIONS OF THE LINGUAL BRANCHES OF THE FIFTH AND EIGHTH NERVES.

To the Editor of the Medical Gazette.

Sir,

In an abstract, by Dr. George Burrows, of "researches relating to the nerves," by Professor Panizza of Pavia, printed in the two last numbers of the Medical Gazette, evidence is adduced to shew that the lingual nerves have in some respects different offices to those hitherto assigned to them by physiologists.

The lingual branches of the ninth (*motor linguæ*) are held by Panizza to be the voluntary nerves of the muscles of the tongue, in accordance with the opinions of other physiologists.

The lingual branches of the fifth (*nervus gustatorius*) are held by the Professor to be nerves of touch, which again accords with the opinion generally received; but he argues against their being nerves of *taste, as well as of touch*, which they are commonly esteemed to be.

The glosso-pharyngeal nerve he supposes to be the nerve on which taste depends.

Upon carefully weighing the evidence adduced by Panizza, I find myself unable to subscribe my assent to his conclusions. My conviction remains the same as it was before I pe-

rused Dr. G. Burrows's paper—namely, that the lingual branches of the fifth are for taste as well as touch; and that the glosso-pharyngeal has a different office. I believe some of the filaments of the glosso-pharyngeal to be sentient, others voluntary—the sensations, to which the nerve ministers, being those which alone can be excited at the root of the tongue, namely, vague sensations of touch, which, when kept up an instant, produce convulsive deglutition, nausea, and spasmodic elevation of the pharynx;—the voluntary actions, to which the nerve ministers, being the motion of some of the upper pharyngeal muscular fibres in swallowing.

The remarks which I have to offer on the present occasion will be directed to two objects: first, to shew that the experiments of Panizza admit of a different interpretation to that which he adopts; secondly, to recapitulate the evidence in proof of the functions of the nerves in question being what I represent them to be.

I.—*Experiments by Panizza considered.*

1. *The lingual branches of the fifth pair divided in a dog.*

"If some milk, or bread, or meat, is offered to the dog, he eats and drinks readily, although, after the operation, it sometimes appears that the dog laps up the milk and masticates his food rather slowly, which may arise from the loss of the sense of touch, or in consequence of the deep wound. If, on the other hand, just enough colocynth, or infusion of quassia, be added to the milk, so as to give a bitter taste without altering the colour, or a piece of bread be dipped into this milk, or, indeed, merely a few drops of the bitter liquid poured between the fibres of a piece of flesh, the animal, which up to this moment had evinced the strongest desire for meat and drink, immediately refuses both one and the other, after taking one mouthful of either. If a piece of meat prepared with the bitter solution is mixed with several others, and the dog accidentally take it into his mouth, he immediately rejects it, and often refuses to eat any more *."

Objection.—The disagreeable impression which the dog evinced may have resulted from the bitter being *tasted* by the soft palate. This objection was foreseen by Panizza; accordingly, Dr. G. Burrows goes on to say—

2. "These facts alone would not prove that the sense of taste still exists in the tongue, because the bitter flavour may be perceived by other parts of the mouth. In order to dissipate all doubt, it is therefore desirable that the bitter substance should merely touch the tongue itself; and to accomplish this, it is best to take a small feather, previously slightly dipped in the bitter fluid, and to draw it lightly along the dorsum of the tongue, taking great care that the fluid does not extend beyond the points touched by the feather. With these precautions the animal still evinces the same marks of strong distaste for the flavour."—Pages 850, 851.

Objection.—In this experiment the dog's mouth must either have been held open all the time of the observation, or have been allowed to close. In the latter case the bitter would have been applied to the soft palate, an organ of taste. In the former it is not singular (without supposing the creature to have been unpleasantly affected by the *bitter*) that it should have moved its tongue and mouth, as if it experienced something disagreeable there.

3. *The glosso-pharyngeal nerves divided in a dog.*

"As soon as the dog had a little recovered himself after the operation of the division of the glosso-pharyngeal nerves, he licked up some water, and ate as freely as if no injury had been done to him. The animal had no other guide than the sense of smell in the choice of his food, so that he will equally take into his mouth disagreeable and hurtful substances as well as pleasant and wholesome. The dog after this experiment ate with equal voracity plain meat as well as that imbued with colocynth, and equally drank the plain milk and that rendered bitter by colocynth. The dog not only devoured a piece of meat which had been beaten up with some colocynth, but even lapped up the remainder of the liquid in the plate."—Page 885.

Objection.—This experiment proves too much. The middle of the soft palate in man, and it is presumable in dogs, enjoys a strong sense of taste: how came that part not to be disagreeably affected with the colocynth? Be-

* Med. Gaz. vol. xvi. p. 850.

sides, there is a tendency in animals, when wounded, to feed; there is likewise a difference of sensibility in different animals; and it is very possible that after such a wound as had been inflicted in this case, the animal should disregard a moderately unpleasant *taste*, when combined with an agreeable *flavour*—that, namely, of milk.

4. Dr. G. Burrows continues—

"Similar experiments were made at the same time with a dog whose lingual nerves of the fifth pair had been divided. After this latter animal had caught in his mouth several pieces of plain meat which were thrown to him, he readily took in the same manner a piece with the bitter *flavour* *; but he had scarcely got it *into his throat* before he was seized with vomiting, and he rejected this piece."—Page 885.

Objection. — The direct conclusion from this experiment is, that the animal had no taste in the fore part of his tongue [*the lingual branch of the fifth being divided*]; but that the soft palate tasted the bitter; and perhaps the root of the tongue, through the glosso-pharyngeal, although it did not taste the bitter, might vaguely *feel* its astringency.

5. Dr. G. Burrows continues—

"A most remarkable contrast between the dogs was now observed; for the animal whose glosso-pharyngeal nerves were divided, immediately ate this rejected piece of meat. Nevertheless, this latter animal still preserved his sense of feeling in the tongue; for immediately on its being pricked the dog howled, and attempted to run away."—P. 885.

Objection.—The natural conclusion from this experiment, taken alone, I admit to be, that the division of the glosso-pharyngeal nerves destroyed the sense of taste. Yet it appears equally certain to me that the dog, in this experiment, *may* have tasted the bitter, yet in spite of it, have been attracted by the flavour of the meat. I beg likewise to refer the reader to the *objection* subjoined to the third paragraph quoted.

II. The experiments of Panizza appearing to me thus to give plausibility to his opinions, but by no means to carry conviction, I proceed to recapitulate the evidence in favour of the opinions which I maintain upon this subject.

1. In the year 1821-2, I performed the experiment in different animals of dividing the ninth nerves and the lingual branches of the fifth. The result of trials made on these animals, which, however, I will not assert were made with as much care as Panizza's, led me to believe that the ninth is for motion, the lingual branches of the fifth for taste and touch jointly.

2. On Monday last I divided, in a dog, on one side the trunk of the glosso-pharyngeal nerve, and on the other, the lingual branch of the same nerve. Mr. Kiernan and Mr. Skey, with whose assistance I made this experiment, (and through whose obligingness I unexpectedly had the opportunity of making it), agreed with me in thinking that the gestures of the animal, when the extract of colocynth was applied to its tongue, evinced that it tasted it.

I must confess, however, that I am disposed to draw conclusions with great caution from experiments on the sensibility of animals after the division of nerves. When nature, in place of being interrogated, is put to the question, she often, like the tortured criminal, gives false answers. But setting my own experimental observations against Panizza's, as sufficient to throw some doubt upon his observations, I think the following argument, derived principally from anatomy, perfectly conclusive on the question.

The sense of taste is most acute at the tip and edges of the tongue. But anatomy shews that branches of the glosso-pharyngeal nerve do not reach the tip of the tongue. Branches of the fifth and of the ninth are distributed there. And as the latter are admitted at all hands to be voluntary only, or not to impart either taste or touch, it follows that the taste and touch of the tip of the tongue must depend upon the lingual branches of the fifth.

When I assert that the sides and tip of the tongue are the seat of the acutest degree of taste, I state a fact which I very carefully verified with Mr. Wheatstone, before the publication of the third edition of my "Outlines of Physiology." It surprises me, therefore, that so good

* The word flavour is here misapplied; *flavour* means a sensation excited in the nose; *taste* alone is excited in the fauces. A dose of salts and senna excites a saline joined with a sweetish taste in the fauces,—together with a peculiar *flavour* in the nostrils.—H. M.

an observer as Panizza should represent the *base* of the tongue as having the highest degree of taste.

Dr. G. Burrows gives the following as Panizza's:—

"In fact, when the glosso-pharyngeal nerve is diligently examined, either in man or animals, as in the dog upon which these experiments were principally performed, it appears that, without giving off a single filament to the muscles through which it passes, the nerve is entirely distributed to the mucous membrane of the tongue and to the surrounding parts, which, in common with the tongue, enjoy the sense of taste: this sense is most exquisite there, where the filaments of the nerve are most abundant — that is, towards the base of the tongue."—P. 885.

What appears to me the most interesting part of Dr. Burrows's communication, is the case which he quotes from the Medical Gazette, vol. xv. p. 120, reported by Mr. Noble, of Manchester.

The patient whose case is reported has want of feeling of one side of the face, from an affection of the fifth nerve of that side. The half of the tongue belonging to that side does not feel, but it *tastes*. It is evident, however, that this remarkable case does not prove the glosso-pharyngeal nerve to be the nerve of taste: it only proves that in hemiplegic anæsthesia of the face, taste may be unaffected, when touch is extinguished. It does not even prove (although, taken with other facts, it renders the conclusion highly probable), that there are different nervous filaments for touch and taste upon the tongue. These *different* nerves (which certainly I am disposed to believe exist) for touch and taste, I think we may fairly conclude to be different filaments of one nerve, and that nerve the lingual branch of the fifth.—I am, sir,

Your obedient servant,

HERBERT MAYO.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

The Anatomy of the Regions interested in the Surgical Operations performed upon the Human Body; with occasional Views of the Pathological Conditions which render the interference of the Surgeon necessary. In a Series of Plates, the size of Life. By J. LEBAUDY, M.D. with Additions. London, 1835. Baillière.

UNQUALIFIED praise implies all possible excellence: for this reason alone we withhold it here. We wish the author had given, with the other engravings, one of the anatomy of the perineum: the omission is the more to be regretted, as all the other views are admirable in design, execution, and (what of course constitutes their chief practical value) the instruction they afford.

For *merely* surgical purposes, these plates are incontestibly the best we have seen; and they moreover possess a claim to preference which many purchasers will be feelingly alive to. They are the *cheapest*. Until the public more highly appreciate and better reward medical men, they must not complain of a niggard economy in the investment of professional capital. The practitioner whose remoteness from cities denies him all the advantages of frequent intercourse, *ought* to be possessed of such a work as M. Lebaudy's; and although we could easily indicate more costly and expanded ones, it would embarrass to point out one more perfect in all the *essentials*. The provinces contain much "patient merit," often distrusting itself upon occasions where confidence would be justifiable; this confidence would be frequently furnished by such a work as the present; and sometimes the patient, spared the fatigue and expense of a journey to the metropolis, will remain to reward the skill and enterprise of the country surgeon.

It is not that we hold these helps to be indispensable, but we are sure their usefulness cannot be denied.—A well-instructed surgeon may have great general fitness, combined with *particular* inaptitude, arising from the *infrequency* of employing the acquisitions made at the schools—acquisitions which, from necessarily falling into desuetude, lose that freshness which constitutes half their value.

Works like the one before us tend to give a perennial character to that knowledge that for lack of use is in danger of *ærugo animi, rubigo ingenii*. We are concerned to be obliged to withhold approval of the view of the "six-month fœtus," which, although a plate of great

beauty and correctness, is wholly out of place and uncalled for, as it refers to no case or contingency involving an operation to which the engraving could contribute any advantage.

We are not satisfied of the necessity for exhibiting the cicatrices of burns, for they are never twice alike, though their effects be generally the same, viz. deformity and impairment of motion. It is not remarked, what will be too often found, that the mere *division* of the bands must be insufficient. Mr. Earle has succeeded in curing this painful deformity, by *dissecting off* the product of cicatrization; the new product by granulation of an incised wound not restraining motion like the tough condensed structure constituting the cicatrix from torrefaction.

We are on the whole highly pleased that this collection of M. Lebaudy's has been placed within the reach of British practitioners: it is entitled to the best encouragement, both as a work of art and utility.

MEDICAL GAZETTE.

Saturday, October 3, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

ILLUSTRATIONS OF IMPARTIALITY.

It has often been remarked, that when a habit of lying has once been formed, the practice gradually increases till the individual at length becomes almost insensible to the distinction between truth and falsehood, and thus makes such unconscionable drafts upon the credulity of his hearers, that even the simplest cease to be imposed upon. Such is the present predicament of a worthy hebdomadal contemporary of ours, who at this season of the year invariably puts forth a manifesto, addressed to pupils, in which he informs them, in the kindest and most disinterested manner, what schools they are to attend and what avoid; lauding some, and condemning others, in a manner which at first sight seems quite incomprehensible, but with as much appearance of candour as if he were quite uninfluenced by any private considerations or personal feelings. Does any one wish for a key to the mystery?—here it is:—let the teachers in a school send a good advertising order, and they will at least escape abuse; but if, in addition to this, they patronize the journal, and, most of all, if they countenance the man (as certain Professors in Gower-street do), they will then be sure to reap a rich reward, in the *honourable* notice taken of them in the Lancet. But alas for those who neglect these precautions!—and more especially if, like some rash and infatuated lecturers in the west, they openly discountenance his journal, and send not even one solitary advertisement to adorn its wrapper and mollify its Editor, then woe betide them!—the door of mercy is shut against them for ever. In short, we assert that schools and teachers are praised or dispraised exactly as suits the interests of our notorious contemporary;—that the very same things are lauded at one establishment which are condemned at another;—that facts as to the expense at different institutions are designedly misrepresented;—that those who have been the objects of ridicule or of invective obtain a truce, or even procure his patronage, as soon as they become opposed to others whom he hates still more;—in a word, that there is no insult which a journalist can offer to the public, which is not almost weekly repeated by our contemporary, who either assumes that his readers are aware of his falsehoods, and yet support his journal, which makes them out to be knaves,—or that they believe the mass of contradictions and absurdities which he indites, and consequently that he holds them to be fools.

If, in support of these assertions, we take up but a number or two of the Lancet, the proofs so crowd upon us

that the difficulty lies only in selecting. We shall at present illustrate one point—its gross, wilful, and interested partiality; and we choose this subject the rather because it is diametrically opposed to the principles on which the journal was founded, and on which it professes to be conducted.

It is well known to those who attend to such subjects, that ever since the North London Hospital was established it has been the leading object of our contemporary *to write it up*. For this purpose every thing connected with it has been systematically represented as affording a brilliant contrast to all similar institutions in this country; *there* we have no "jobbing," no "hole-and-corner work," no "corruption," no "abuses." Now the great complaint against the other hospitals—that which is said to be the root of all the evils which exist—is the mode of electing the officers. It is not our present purpose to inquire whether this be so or not; but as such is the recorded opinion of the Lancet — oft reiterated, and with many an invective — why, we ask, did not the same denunciations, and the same virtuous indignation, attend the election of officers to the Valetudinarium? Election! said we? there was nothing of the kind; the officers were installed as a matter of course, without even the form of an election. We do not object to this, under the circumstances; but then we do say that if the same thing had been done elsewhere, the Lancet would have been trumpet-tongued upon the subject.

It will be said, perhaps, that this was only at the first establishment of the hospital, and that the appointment of the professors in the *soi-disant University* was unavoidable. Be it so: but then comes the additional surgeoncy; how was that managed? Was the vacancy advertised? Were candidates invited? Was an election made? Was the most eligible chosen by the subscribers; or was it done by the *concours?* Will it be credited that the appointment was made by none of those modes! that it was matter of private arrangement! that it was a business of negociation! that it was done secretly and in silence! Certain parties cast about for a surgeon; they treated with Mr. Tyrrell; they treated with others; and, finally, they ended by coming to an agreement with Mr. Liston, who, it was arranged, was to be surgeon to the North London Hospital, while the importance attached to his acquisition was proved—by his being permitted to lecture in another school! Where, meanwhile, was he who professes to guard the profession and the public from all "hole and corner" proceedings, when this singular mode of *electing* an hospital surgeon was adopted? Where did the patron of the *Concours* hide his "manly" head*? We know not where,—perhaps at a *conversazione* in the London *University*, learning manners, against the conference with the Lords; perhaps at the House of Commons, trying how he might best oppose the bill against the pirating of lectures. But it matters not where; Cerberus was pacified with a sop; and means have been found to render the dog that bays so loud in other places muzzled and dumb in Gower-Street.

Again, we have been told, and it has been repeated *usque ad nauseam*, that the school in Gower-Street is cheaper than any other which claims to be respectable. This is not the fact, as we formerly demonstrated, by giving a tabular view of the fees at the various institutions in London, by which it was proved, beyond the possibility of contradiction, that the establishment in Gower-Street was very considerably more expensive than any other school

* See an extract in various London papers, from the Maidstone Gazette.

in the metropolis: since that time, and probably in consequence of our exposé, the fees have been somewhat reduced; but for unlimited attendance, still remain by much the highest in London. But it is said that the fees at the Valetudinarium are—as undoubtedly they ought to be—much less than at the great hospitals: let us see. The perpetual ticket is certainly less than at the large hospitals; but between the expense for the time and manner in which the immense majority of pupils attend, the difference is a mere trifle. Thus the common fee for attendance on the medical practice of the large hospitals during one year (lately increased to eighteen months on the same terms), is fifteen guineas. But hear what the prospectus of the North London Hospital says:—"For attendance during one year on the physicians' OR surgeons' practice, *separately*, 15*l.* 15*s.*"!! So that the medical practice there, is actually as expensive as at hospitals containing three or four times the number of patients. For attendance on the surgeons' practice at various other, and much larger, hospitals during one year, the usual fee is twenty guineas, or five guineas more than in Gower-Street; an excess, however, which has far more than an equivalent in the superiority of the opportunities of acquiring knowledge. It is not the mere difference of money asked or given that makes one thing cheap and another dear—something depends on the value of the articles; and estimated by this rule, the fee at the North London Hospital is preposterously high. How, then, is it that attendance at the Valetudinarium can be made to appear in any sense less expensive than elsewhere? Why, except as regards unlimited attendance, it is done by a cunning and unworthy manœuvre. The ticket, though nearly the same price as elsewhere, if the pupils profess to do no more than they profitably can, is yet much cheaper if they pretend to do, what we boldly assert no pupil can do, or even attempts, for any purpose but to obtain a certificate—namely, attend both the medical and surgical practice at once; that is, the practice of seven different persons at the same time: "attendance (says the prospectus, and echoes the Lancet) during one year upon the physicians' and surgeons' practice, 21*l.*" The plain English of all which is simply this:—The fee for the medical and surgical practice "separately,"—the mode in which alone it can be profitably attended, is very nearly the same at the North London as at the other metropolitan hospitals; while, viewed in relation to the variety of cases, the number of dresserships, and other advantages, it is infinitely higher;—but then, as aforesaid, the fee for a *certificate* of medical and surgical attendance is greatly less.

The mention of the dresserships reminds us of another point. The Editor of the Lancet has thought fit to institute a comparison between *his* hospital and St. George's, in reference to certain advantages enjoyed by pupils. "The dresserships (he informs us) at the North London Hospital are free to all perpetual pupils without the payment of any fee!" By which it appears that the dresserships *are confined to the perpetual pupils;* a limitation which becomes necessary in so small an hospital, and is no doubt judicious; but at St. George's, which our contemporary has himself selected for comparison, we find that "pupils entering for twelve months are allowed to dress the patients for three months without additional fee." This is rather a blunder on the part of our *honourable* opponent; but in truth the whole article alluded to is in a strain which admits of but one reasonable conjecture as to the condition of the writer when he penned it. Thus, among various other flights of fancy, he is pleased to assume that the

expenses of a pupil at St. George's, for board and lodging, would come to 120*l.* per annum, the gross amount of which, for three years, in defiance of all the rules of Cocker, he discovers to be 380*l.*!—and while the items, taking them at his own extravagant calculations, give a sum, the "tottle of the whole" of which even his friend Mr. Hume could only make 480*l.* 7*s.*, he, in adding up, finds to be 600*l.* 7*s.* * !!

But the inconsistencies are endless; for again, as we have seen above, in order to make up a fictitious amount, the expense of the pupil for board and lodging is calculated at 120*l.* per annum; and yet the amount charged by the Hospital for his board and lodging, namely, 50*l.*—(or 70*l.* less than the Lancet's estimate)—is printed in italics, and declared to be a "precious picture." What can the blockhead mean? Surely either the charge is moderate, or his own calculation is extravagant! But to reason upon such data is in vain; and unless the conjecture we have hazarded above afford a clue to the origin of this tissue of blundering balderdash, we must leave the cause of the mystification unexplained.

In every thing the same gross partiality and favoritism are manifested, and stand contrasted with corresponding demonstrations of jealousy and malevolence. At the Gower-Street School the system of giving prizes was very judiciously adopted, and the Lancet teemed with flaming accounts of the examinations, meetings, and distributions, therewith connected. The same plan was adopted at St. Bartholomew's, and it is now declared to be "all humbug and quackery"! Does any one for a moment doubt that this originates in his old grudge against Messrs. Stanley and Earle, and his newly-declared war against Mr. Lawrence?

Great was his indignation when it was insinuated that the Valetudinarium was not quite so large as could be wished:—now he ridicules and sneers at the Charing-Cross Hospital; yet there is little or no difference in the size of the two. How comes it that his kind anxiety to guard the pupils of King's College from the evils of insufficient clinical opportunities extends not to his young friends in Gower-Street?

There are two schools at Hyde Park Corner—one in the Hospital, and one adjoining; at neither is a course of chemistry given, an omission which is understood to be owing to the acknowledged excellence of the lectures of Messrs. Brande and Faraday, in Albemarle-Street. The Lancet draws up a spurious prospectus of the Hospital-School, and introduces the words "Chemistry—none given:" he also gives a prospectus of the other school, and announces "Chemistry—at the Royal Institution;" by which, of course, he means to imply that there are chemical lectures connected with one school, but not with the other—whereas the chemistry is equally in the vicinity of both, and equally independent of them. So also with regard to anatomy: at the Hospital-School there is said to be "none given," although the new theatre and whole establishment in Kinnerton-Street are inferior to none, and the dissecting-room superior to any in London. We observe, too, that the pupils are advised to attend the lectures which have been set up in opposition to those in the Hospital. Now whether this advice be good or otherwise, we cannot pretend to say; but we happen to remember that some of the principal teachers now patronised by the Lancet have heretofore been repeatedly attacked in it; and, indeed, it is but very lately that one of the chief of them was week after week held

* The sums (see Lancet, September 5, p. 745), are—

	£	s.	d.
	16	16	0
	1	1	0
	52	10	0
	50	0	0

Total......	480	7	0
But, according to the Lancet	600	7	0 !!!

up to ridicule and scorn in its consistent pages! All this to the uninitiated might seem the very lunacy of malice, but yet it works by method, and proves what we said before, namely, that they who have been abused by the Editor of the Lancet may obtain his favour by becoming opposed to those whom he hates yet more. Who can fail to see, in these paltry manœuvres of our contemporary, the workings of that hostility to Sir Benjamin Brodie which betrays itself on all occasions—of that vexation with Dr. Seymour which his active opposition of the Lancet's protegés at the late discussion on the laws of the hospital engendered—and of that hatred of Dr. Macleod which has rankled for years in his bosom as—

"A worm that will not sleep, and never dies."

We undertook to prove the Lancet's partiality, and such are some of our illustrations; many remain behind, but our space shortens, and enough, we think, has been done to open the eyes of the most simple, and to convince the youngest tyro that none but a veritable *Johnny Newcome* would put himself in the leading-strings of such a guide.

EASTERN PROVINCIAL MEDICAL ASSOCIATION.

A meeting, which was very numerously attended, took place at the Guildhall, Bury St. Edmund's, on Friday, the 25th ult., for the purpose of forming a society, consisting of medical practitioners residing in the adjoining counties. The immediate objects in view are the collecting of information relative to medicine and the collateral sciences, and maintaining the respectability of the profession by promoting friendly intercourse between its members. Dr. Probart presided, and Mr. Crosse, of Norwich, acted as honorary secretary. The latter gentleman addressed the meeting at considerable length, and forcibly illustrated the advantages likely to accrue from such an institution. Many other gentlemen afterwards expressed their sentiments; and the establishment of an "Eastern Provincial Medical and Surgical Association" was unanimously agreed to. We regret that our space will not permit us to give insertion to the speeches made on the occasion; they will be found at length in the Bury Herald.

HOSPITALS AND THEIR REGULATIONS.

Our respected contemporary, the Medico-Chirurgical Review, after noticing a nonsensical tirade which lately appeared in a weekly journal under the above title, proceeds to make the following observations:—

The gist of all this lacrymation is, that hospital surgeons and physicians are paid. Really we see no abstract injustice in this; on the contrary, we think, and many others think so too, that the public services of medical men are not paid enough. A ruinous competition has ground down the profession into a starveling race—fellows who, like the opposition coachmen, not only take their passengers for nothing, but regale them with brandy and water on the road. Our dispensaries and many of our infirmaries have the services of physicians and surgeons for nothing—our hospitals have those services gratuitously also, so far as the hospital funds are concerned—and the remuneration, such as it is, is derived from the attendance of pupils. Now we do not see that Mr. A. or B. has any natural or indefeasible right to come from Yorkshire to London, to walk into the first hospital that presents itself, and accosting an *unpaid* physician or surgeon, to request him to show him his practice, explain his views, and exhibit his skill in the manner best adapted for his convenience. We find no such principle laid down even in 'The Rights of Man, by Tom Paine,' and we think it would be difficult for the most ingenious Owenite to prove it. But setting aside the claim to remuneration on the part of the medical officers of hospitals, and disregarding rights, let us look upon the question as one of expediency. In the first place, it may be stated as a general law that men work better when paid for their exertions than when unpaid. Perhaps editors are a class of men whose liberality is as great as can be expected from any members of a civilized community. None are so eloquent as they on the necessity and advantages of liberality and

disinterestedness — none can be more earnest in pointing out abuses, and jobs, and peculation. Yet in practice we find editors work nothing the worse for having a tolerable salary from a publisher, or a copious list of subscribers. The most liberal and patriotic writer never, so far as we can see, complains of finding his liberality and patriotism damped by their reward. Nay, singular as it may appear, the more he is encouraged, the more money he makes, the warmer is the complexion of his liberality. Were a new reforming journal to be established on the broad bottom of no pay for any person concerned in its writing, publishing, or printing, we are inclined to think there would not be a very lively contest for the situations of editor, publisher, or printer. In short, look where we will—at the bar—the pulpit -the judicial bench—the ministerial office—the ‘ gallant ship’—or the embattled field—we see that pay for services performed is admitted as a principle, and acted on in practice, with the best effects. Why, then, should the unhappy hospital functionary be singled out as the only man who is to work for nothing—why are the feelings of human nature to be disregarded in his case—and why is he to be supposed capable of doing what nobody else is asked to do, to work well and willingly without reward?

No doubt the principle of pay may be admitted, yet exception may be taken at its mode and its amount. In the case of the hospitals, we think that the method of remuneration is by no means bad. As the charitable institutions greatly depend upon private subscriptions, and as, whether that be so or not, the funds were intended, as exclusively as possible, for charity's sake, the less taken from those funds, for purposes not strictly charitable, the better.

If a man becomes surgeon to a hospital where he is not paid, he binds himself to perform certain duties to the patients; and if those duties are not performed, the persons who elected him have, or ought to have, the power of punishing him by suspension, or even by dismissal from his office. But pupils may be said to constitute an excrescence on a charitable institution—they are not essentially connected with it. Unless it be a surgeon's or physician's interest to pay the utmost attention to pupils, there is and there can be no efficient mode of preventing his neglect of them. The mere routine performance of specified duties is utterly inadequate to promote their advancement—there must be a disposition to direct, encourage, and assist. That disposition, we repeat, can be ensured by remuneration only. And from whom can remuneration more properly come than from those who are to derive advantage from it?

If it were otherwise an object of importance to protect the pupil from expense, if it were better that he should pay no fees, and that his entrance into the profession should be made as cheap as possible, we might feel inclined to look for some other mode of payment than such fees afford. But, so far from it being advisable to render admission into the profession very cheap, we think it would be well if it were more difficult than it is. Our ranks are at present more than sufficiently crowded, and the rate of profit is fearfully beaten down by the ruinous struggles of starving competitors for bread. Not a town, not a hamlet, but bears evidence to this—not a medical practitioner but directly or indirectly feels it. It is an evil that has increased, is increasing, and ought to be diminished. Let the common sense of our readers decide, whether that evil will be decreased by greatly cheapening medical education. For our own parts, we do not hesitate to express our opinion, popular or unpopular, liberal or illiberal as it may appear. We think the facilities for reception into the profession should not be too great; but we do not think that, to effect the desirable purpose of preventing an indiscriminate rush into our ranks, arbitrary or unreasonable tolls should be levied. Education should not be merely made dear—it should be dear only by being extensive. Whether our numbers be great or small, our real respectability can only be secured by securing the highest amount of attainments.

We agree with our contemporary, that the offices of house-surgeon, dresser, clinical clerk, and others of the same description, should not be obtained by the payment of money. They ought to be the reward of industry and merit; at some of the metropolitan hospitals they are so. At St. George's Hospital, for example, no fee is paid for any of the situations in question.

But those officers who reside in the hospital pay a small sum for their board in the institution, which is not unfair, for a young man must eat and drink, and probably it costs him less to live in the hospital than out of it.

LECTURES ON DISEASES OF THE RECTUM;

Delivered at St. George's Hospital,
By Sir B. C. Brodie, Bart.

[The preceding Lectures will be found in the volume of the Gazette just concluded.]

ABSCESSES CONNECTED WITH THE RECTUM—FISTULA IN ANO.

I have already mentioned two kinds of abscesses which occur in connexion with piles. First, an abscess forms in an external pile, and bursts externally. Sometimes it will heal and not form again; at other times it will heal, and then form a second time. I stated that the shortest way of curing this kind of abscess was to excise the pile in which it is situated. Secondly, an abscess forms in internal piles, which bursts into the cavity of the rectum; and this sometimes heals spontaneously, and sometimes not. When an internal pile, in which an abscess has formed, becomes protruded externally, you may remove it either by the scissars or by ligature; or where that cannot be done, the patient may be cured by a long-continued course of Ward's paste, or *confectio piperis composita*. Then I mentioned, in a former lecture, abscesses which occur in connexion with stricture of the rectum, or with malignant and other organic diseases of that organ. None of these, however, are the abscesses which terminate in the disease commonly called *fistula in ano*.

Abscesses which become fistulous generally occur in persons of costive bowels. Those who have been long subject to piles are more liable to them than others; I suppose in consequence of the inflammation originally occurring in the pile extending to the neighbouring textures. Sometimes this inflammation, which precedes the formation of such an abscess, occasions the patient so little pain that he is hardly conscious of any disease existing in the part. I remember a gentleman in whom an abscess formed by the side of the rectum: and who was not conscious of any local symptoms. But he had been for some time subject to headach, was languid, forced to go home and lie down in the middle of the day. One day, walking in the streets the abscess burst; and that was the first thing which gave him any notion of its existence. In general, however, the abscess forms, attended, in the first instance, by a moderate degree of pain, and some tumefaction and induration are perceptible in the neighbourhood of the anus. The inflammation goes on, the pain and tenderness become greater, the induration more extensive, and at last the parts are so painful and tender that the patient can scarcely walk. The system sympathizes with the local inflammation, and the pulse becomes frequent, the skin hot, and perhaps the patient has rigors. Thus the symptoms run on until the abscess bursts. Sometimes it bursts into the rectum, and not externally; more frequently it presents itself externally, and bursts at a little distance from the anus. In many cases the abscess communicates with the inside of the gut, and opens externally also. As soon as the abscess has burst, the symptoms are all relieved. The pus which is discharged is seldom healthy, like that formed in an abscess situated elsewhere. For the most part it is dark-coloured, putrid, and offensive. Whether these qualities are given to the pus in consequence of a small quantity of fæces penetrating through an aperture in the mucous membrane into the cavity of the abscess, or whether it is that there is any transudation of fæculent matter, or gas, through the mucous membrane, without there actually being an aperture in it, I am unable to determine. I think it very likely that in many cases, at least, the offensive quality of the pus is to be attributed merely to transudation. I have known many facts which prove that transudation, to a certain extent, takes place in living bodies as well as in the dead subject. For example, a gentleman had an encysted tumor in the neck, which contained cheesy matter, such as is found in the common subcutaneous encysted tumors. This cheesy matter had become rancid, and when the tumor was dissected out the smell was exceedingly disgusting. Before the operation, the effluvia penetrated not only through the coats of the cyst, but also through the skin of the neck; so that you could scarcely bear to stand near the patient: I mean that you could smell the rancid contents of the cyst, when the cyst itself and the skin over it were entire.

When the abscess has burst externally, it sometimes heals as any other abscess would do. This, however, is only an exception to a general rule. For the most part the orifice of it remains open, and it continues to discharge a little matter; or if the orifice closes, it is only for a time, the matter being again collected at the bottom of the orifice, and the skin once more ulcerating. In the course of time the margin of the orifice becomes hard and projecting, a sort of button or tubercle being formed round it, and it is while in this

state that the abscess is said to be converted into a *fistula in ano.*

I say the general rule is, that this kind of abscess does not heal. But abscesses in other situations do, unless there is some particular local cause operating, or the patient's general health be bad. An abscess may be prevented from healing by a portion of dead bone, by a diseased gland, or by a piece of dead tendon or ligament at the bottom of it. But what is it that prevents an abscess from healing that forms by the side of the rectum? Here is a preparation [presenting it] which I think will explain how this happens. Here has been a *fistula in ano;* the mucous membrane has been dissected off, and a piece of bougie has been passed into the *fistula.* The fibres of the sphincter muscle pass over the bougie, and they pass under it also, so that, as you perceive, the sinus in fact is in the substance of the sphincter muscle; and I am certain that that is generally the case. If you look at the position of the sinus in the living person, you will be satisfied that for the most part it runs through the sphincter muscle; and dissection, as you have seen, confirms the observation. The sphincter muscle is constantly in motion, contracting and dilating, and consequently there is not the repose which is necessary for the cure of the abscess. The action of the muscle, in fact, prevents the abscess from becoming consolidated. In illustration of the effect of muscular action in preventing the healing of an abscess, I may mention this case:—A man was in the hospital on account of an abscess which burrowed in the muscles of the thigh. There was no lodgment of matter, no dead bone, no diseased glands at the bottom; but the abscess penetrated in various directions among the muscles, and they were in constant action around it. As long as the patient was walking about and using the limb, the abscess never healed. I put him to bed, and kept the limb in a state of perfect repose, as if the bone had been broken. Under this treatment the abscess, which would not heal before, healed readily.

I have said that the abscess forms in the vicinity of the gut. But it may extend in any direction; so that there may be a very large abscess running all the way from the rectum to the *nates.* Such an extension of the abscess makes no alteration in its character: it is still a *fistula in ano.*

An abscess sometimes forms high up by the side of the rectum, above the sphincter muscle; but this is of comparatively rare occurrence. These abscesses attain a very large size before the patient suffers much pain or inconvenience. There is at first merely a sense of bearing-down of the rectum, occasioned by the pressure of the abscess on it; but as the abscess increases in size, the patient has violent painful spasms, and a constant feeling as if he wanted to pass a motion, while there are no fæces in the bowel. His sufferings are now excessive. You examine the external parts, and you see nothing. You introduce your finger into the rectum, and there you perceive the abscess pressing on one side of the gut, and very much diminishing its diameter. Having thus ascertained the position of the abscess, if you examine the external parts again, although you could discover nothing in the first instance, you will probably be able to detect it, deep-seated as it is, at the side of the anus. More resistance will be offered to the pressure of the finger here than elsewhere; or if you introduce two fingers of the left hand into the rectum, which you may easily do, and press on the abscess from within, you will make it actually bulge a little externally. These abscesses high up by the side of the rectum give the patient an extraordinary degree of suffering, and that for a great length of time. If left to themselves, they generally burst into the rectum. It is your business, as I shall explain to you hereafter, to give the abscess an opening externally, before it has made another opening for itself.

I have told you that abscesses of the rectum occur in persons who are costive, and have been the subjects of piles; but I have no doubt that sometimes they are produced by foreign bodies penetrating through the mucous membrane of the bowel and sphincter muscle into the cellular membrane. I was sent for to a gentleman who had a very uneasy feeling in the rectum. I thought he laboured under internal piles, and prescribed him something which, however, did not relieve him. The next day, as he was no better, I examined the rectum, and found a hard substance sticking in the mucous membrane. With some difficulty I extracted it, and found it to be part of the core of an apple, which the patient had eaten the day before. Suppose this had not been extracted, the apple core, having penetrated through the mucous membrane, would have produced an abscess by the side of the gut. I was sent for to another gentleman, a year or two ago, with a very large abscess formed by the side of the gut. He suffered a great deal of local pain; had a very frequent pulse, brown dry tongue, very hot skin, and typhoid symptoms. I opened the abscess, and let out a quantity of very putrid offensive matter, which sufficiently explained the typhoid symptoms under which the patient laboured. After I had opened the abscess, I introduced my finger into the cavity, and, sticking across it, I found a long fish bone, which I extracted. The fish bone had evidently penetrated through

the mucous membrane of the bowel, and in all probability some small portion of feculent matter had passed by the side of the fish bone, thus accounting for the remarkable putridity of the matter.

A *fistula in perineo* is a very different affection from a *fistula in ano*. It is an abscess communicating with the urethra, and the urine flows through it when the patient makes water.

It is generally caused by some obstruction in the urethra, and all that is necessary for its cure is to dilate the obstructed canal.

Sometimes, however, a *fistula in perineo* is complicated with the disease of which I am now treating. I have seen of this only a very few examples. One of these is a patient in the hospital at present. This man had, if I remember right, a severe attack of gonorrhœa. This was followed by an abscess communicating with the urethra, which, instead of making its way directly to the perineum, ran (I suppose) behind the triangular ligament of the perineum to the rectum, and then again burrowed in front of the latter, and at last burst by the side of the anus; so that it had all the characters of a *fistula in ano*, though it communicated at the same time with the perineum and urethra.

I have mentioned that abscesses connected with the rectum may occur in persons in the best state of health. But those who are in bad health are more liable to them than others. They occur frequently in connexion with disease of the lungs: patients labouring under tubercles and abscesses of the lungs being very liable to abscesses by the side of the rectum, which have all the characters of common *fistula in ano*. You should always take care, before you operate on a patient for fistula, to ascertain whether the lungs are sound. Persons with diseased liver and other visceral diseases, are also liable to the formation of these abscesses. The distinction of these cases from those which occur in otherwise healthy subjects, is very important, inasmuch as the practice which is proper in the one case is quite improper in the other.

I have said that for the most part an abscess by the side of the rectum has no disposition to heal. What, then, will happen if you do nothing in such a case? The fistula will remain open, sometimes discharging little and sometimes much; the orifice alterately closing and opening. I have known several cases in which a neglected fistula has continued in this state for years. This, however, is what ought not to be allowed, for sooner or later the day of reckoning comes, and the fistula which was a trifling disease originally, assumes a formidable character. A gentleman who had had an abscess by the side of the rectum for twenty years, and it went on as I have mentioned, sometimes discharging a little matter, then stopping, and then discharging again. Some three or four months before I was consulted the external orifice closed, and did not open again as usual. By and by he began to suffer a great deal of pain, became exceedingly ill, and I was sent for to see him in the country. He appeared to be all but dying; he was not in *articulo mortis*, but I do not think he would have lived twenty-four hours longer. I examined the rectum, and satisfied myself that there was one of those large deep abscesses which I have just now described. I introduced a lancet by the side of the gut, and thrust it in quite up to the handle before I could reach the matter. I was sure of the right direction of the lancet, and carried it onwards until I succeeded in my object. When a little matter had escaped, I introduced a probe-pointed bistoury, and dilated the orifice freely. Immediately there flowed a pint or more of matter so putrid as to cause the whole house to stink; so that you could smell it in every room. This operation saved the patient's life. It was necessary, on a future day, to enlarge the opening still further into the rectum, because the matter did not escape with sufficient freedom; but from that time the patient went on well. This monstrous and dangerous disease had been produced in consequence of the neglect of a trifling affection, which might easily have been cured in the beginning.

A *fistula in ano* is sometimes a simple fistula, such as I have before mentioned. It may communicate with the gut and not open externally; or *vice versâ*; or it may open externally, and communicate with the inside of the gut also. But sometimes the fistula is complicated, so that there is a sinus in one direction, and a second in another. There may be even three or four different sinuses produced, by the abscess burrowing first in one direction, and then being stopped and burrowing in another; thus pursuing a circuitous course until it finds its way to the surface. I have adverted to a case in which a common *fistula in ano* gave rise to the formation of a large deep-seated abscess, high up by the side of the rectum; and I have no doubt that many such deep-seated abscesses are formed in this manner. Sometimes, in attempting to cure what seems to be a common fistula, you find that it does not get well as usual, and then at last you discover a large abscess above, which prevented the closing of the smaller sinus below.

Treatment.—When inflammation takes place by the side of the gut, such as you might expect to terminate in abscess, it will do so in most cases in spite of all

your efforts to prevent it. There are, however, some exceptions to this rule; I have every now and then known a patient who has been thus threatened put on leeches and keep quiet, the inflammation subsiding afterwards without suppuration; but in nineteen cases out of twenty the abscess sooner or later forms. If you are called to the patient quite *early* in the disease, you may put on leeches, keep him quiet, and give him the small chance of preventing suppuration which this treatment will afford; but otherwise your best plan is to poultice the part, foment it, and encourage the formation of matter as much as possible. When you are satisfied that matter has formed, the sooner you open the abscess the better; for the longer you leave it the more mischief will the matter do, by burrowing in the neighbourhood of the gut. You need not wait till the matter can be felt externally; if the symptoms indicate that matter has formed, and you feel the hardness externally, you may venture to introduce your lancet. Bear in mind the anatomical position of the parts, and you will be able to introduce a lancet with perfect safety, until you reach the cavity of the abscess, even although it be very deep seated.

I have stated that the abscess sometimes heals, but that it generally does not, and that then it forms a fistula. What are you to do in this stage of the disease? how are you to heal the fistula? It was formerly the custom to dissect out all the hard callous parts around the abscess, and a most frightful operation it was. I believe it was Mr. Pott who made this great improvement in this department of surgery, by showing that such a dissection is quite unnecessary, and that all that is required is, to lay the abscess freely open into the bowel. If you look at this preparation [presenting it], I think you will see how it is that this simple operation is sufficient to produce a cure. The matter runs freely out of the abscess, and yet the patient does not get well, because, as I told you, there are the fibres of the sphincter muscle constantly acting on the abscess, and preventing the healing process. When the abscess is laid open, the fibres between it and the bowel must be divided, and the sphincter muscle being thus set at liberty, not only is there a free and immediate escape of the matter, but the action of the muscle, which prevents the healing of the abscess, is put an end to. This, then, is the mode of curing the abscess: lay it open into the bowel, dividing at the same time the fibres of the sphincter muscle which lie over it.

But before I proceed to describe the operation in detail, and to explain all the various circumstances which require to be attended to, as connected with it, I must speak to you concerning the cases in which the operation is, and those in which it is not, proper to be performed. It may be performed in healthy persons, but not in those who are in a state of disease. The operation is proper if the rectum be otherwise sound, if the lungs and the liver be sound, if there be no organic or visceral disease; but if the rectum be not otherwise in a healthy state, if there be stricture, carcinoma, or any other disease of this organ, the operation ought not to be performed; for under these circumstances the sinus will not heal, even though it be laid open. If the patient labour under visceral disease, it is seldom that the abscess will heal; but if it should, the visceral disease will make increased progress, and the patient will die sooner if the operation be performed than if it were let alone. If a person come to you with *fistula in ano*, and he looks as if he laboured under some other disease, always inquire into the state of his general health, and take care never to perform the operation except when you are satisfied that his health is good.

GENERAL LYING-IN HOSPITAL.

MIDWIFERY REPORTS.

By Edward Rigby, M.D. F.L.S. &c.

[Continued from preceding vol. page 896.]

Uterine Hæmorrhage.

February 24, 1834.—Susan Templeton, æt. 38, delivered of a boy; seventh child. Presentation and labour natural; child large, cord once round the neck. About ten minutes after its birth slight hæmorrhage made its appearance, and on feeling the uterus (which had been tolerably well contracted at first) it was found to have yielded considerably. After gentle friction over the uterine region, some very large clots of blood were expelled; the placenta still refused to quit the uterus, the neck of which was strongly contracted upon it. Profuse hæmorrhage then came on, and it was found necessary to introduce the hand into the womb for the purpose of extraction; this was accomplished with little difficulty. The patient was very faint, though not in a state of complete syncope. No pulse could be felt at the wrist; the extremities were cold, and she complained of numbness in them; voice feeble; face and lips blanched; eyes sunk. Sp. ammon. arom. was given, and she had some brandy in her gruel; friction to the extremities. The colour then began to return to the cheeks and lips, and the voice became stronger; but it was a considerable time before the pulse at the wrist returned, and

then but feebly. A firm bandage was put round the abdomen, with a compress over the uterus; she was removed to a bed in the ward, and a draught of tinct. hyosc. ammon. arom. and camphor mixture was given.

10 P.M. — Has slept a little, but the hæmorrhage returned, which caused her to faint, as nurse reports; pulse again could not be felt at the wrist, but gradually and feebly returned after taking some brandy. Cold cloths were applied to the external parts. She recovered without any untoward symptom.

It is difficult always to prove whether the non-expulsion of the placenta is owing to its not being yet completely separated, or to its being retained by contraction of the os uteri, or whether it depends partly on both causes. Professor Naegele rather deprecates the use of friction to the abdomen for the purpose of exciting the uterus to contract, as being liable to bring on irregular action of its fibres; and perhaps in this case the firmness with which the os uteri was contracted might be in part owing to the friction used. The hæmorrhage returning in about four hours afterwards, shews how important a part of a nurse's duty it is to watch her patient narrowly for several hours after labour. In no case are we secure against hæmorrhage. Thus in the following case hæmorrhage came on four hours after labour, although none had occurred immediately after the birth of the child to justify our expecting an attack.

September 18, 1835.—Jane Garwood, æt. 27, delivered of a boy; first child. Labour natural and easy; second position. A fold of the cord prolapsed between the neck and perineum, but as it was not so pressed as to endanger the child's safety, the expulsion of the body was allowed to take place by the natural efforts. Smart hæmorrhage occurred after she had been in bed four hours; it was easily repressed by cold applications and diminishing the quantity of bed clothes, and did not return (the night was sultry).

There can be little doubt but that this attack of hæmorrhage was in great measure produced by the heat of the weather. Nurses are too ready to "cover a patient up comfortable," as they call it, which is little else than to keep her in a reeking perspiration; and nothing is more likely than this to produce inertia uteri.

Hæmorrhage thirty-six hours for Labour.

The next case of hæmorrhage is still more remarkable, it having come on *thirty-six hours after labour*. It was a twin case, and in the debilitated constitution of an habitual gin drinker, proved fatal. My friend Dr. Barr has furnished me with the report.

"February 10, 1834.—Sarah Grieve, delivered of twins (girls); fifth labour. The first child presented with the head, second with feet; former rather larger of the two. Not much above ten minutes elapsed between the birth of the one and the other. The placentæ were not adherent throughout their contiguous edges, a portion in the centre being left unattached. But little hæmorrhage followed their expulsion, although there was a considerable discharge of liquor amnii. She is a pale unhealthy-looking woman, very fretful and spiritless, has been out of health for the last few months, and much troubled with cough and mucous expectoration. About thirty-six hours after delivery she was attacked with rather a profuse flooding, felt weak and faint; the nurse said that a minute before I saw her she had fainted away. Cold water was dashed on the face, and wet cloths applied to the hypogastric region. Cold vinegar and water was injected into the vagina after the removal of rather a large coagulum, and the abdomen was tightly bandaged. The hæmorrhage at length ceased, after returning somewhat at intervals, being especially excited by the cough. She had some refreshing sleep after taking 10 gr. of ext. hyosc. and 5 gr. of ext. conii.

"13th.—Feels very weak; dozes a good deal, but tosses about much; cough very troublesome; pulse 140, bounding, but compressible; skin hot and dry; tongue clean and moist; is thirsty; bowels moved twice during the day. Sound on percussion over the chest clear.

Mist. Salin. c. Vin. Antim. 4tis horis.

"14th.—Much the same; complains of no pain or tenderness; no delirium; pulse as frequent, but weaker; bowels relaxed, motions sometimes passed in bed. (Dr. Rigby saw her to-day).

> Ammon. Carb. gr. v.; Aquæ Menth. Pip. ℥iss. 4tis. horis. To add 10 drops of Tinct. Opii occasionally. To have some gin and water, to which she says she is daily accustomed.

"15th.—No improvement; respiration hurried, but less troubled with cough; has had slight moisture on the skin, which was only transient; eyes dull and heavy; complains of occasional dimness of sight and confusion of mind; pulse 130, soft and weak; bowels less relaxed, stools watery and curdy.

> Ammon. Carb. c. Confect. Arom. and Træ. Cinchon. Comp. ex Aq. Menth. Pip. 4tis vel 3tiis horis.

Dr. Locock saw her shortly after, and ordered, in addition to the mixture,

> Hyd. c. Cretæ, gr. v.; Pulv. Rhæi.; Pulv. Ipecac. aa. gr. iij. ft. Pulv. bis die sum.

"16th.—Weaker; very restless during

the night; complains of numbness of limbs, and general uneasiness. Early this morning had a catching pain of the side on coughing or full inspiration, which was relieved by mustard poultice. Pulse 141, feeble; skin dry; tongue moist and clean; bowels moved three times during the night, stools more natural.

Emulsion of egg and brandy.
Contin. Medicam. Capt. Liq. Opii sed. ℥ss. h. s.

" 17th.—Gradually sinking. Died at 2 P.M."

Remarks.—It is curious to see what a variety of anomalous symptoms will appear in patients of this sort, who have been deprived of their accustomed stimulus, and how really seriously ill they will become under such circumstances, even in spite of medical treatment. I have seen miserable pallid wretches, victims of spirit drinking, in whom, after being a few days in the hospital, there has been such debility, sleeplessness, and derangement of bowels, such irritability of stomach towards every species of food, and with such constant vomiting and anorexia, that considerable fears were excited for their life, and where the glass of gin daily has " done more good than all the physic in the doctor's shop." I have seen cases of habitual spirit drinkers where this was even necessary on the second day after labour. It is seldom that we are made aware of this fact by the patients themselves; and I have frequently known them even deny their being spirit-drinkers. But besides the above-mentioned symptoms, there is an irritable, peevish, discontented manner, which is very characteristic. The hæmorrhage in this case effectually accounted for the appearance of debility, and lulled any suspicions respecting her intemperate habits; but I am half inclined to suspect, that could we have been aware of it, we might by a moderate supply of the accustomed stimulus, even shortly after labour, have kept up that degree of tone and uterine contraction which would have effectually prevented the attack of hæmorrhage. It was the general atony of the system, in which the uterus partook, and which was doubtless increased by the demand upon its powers from her having had twins. A sectio cadaveris was not permitted by her friends.

No case of unusually precipitate labour has occurred during 1834. Two or three patients have put off coming to so late a moment that they have either been delivered in the vehicle which brought them, or on the floor before they could be put to bed; but no untoward result has happened, no rupture of the cord, inversion of the uterus, &c. I therefore pass on to

Prolapsus of the Cord.

The following case was reported by my friend Dr. Barr, who turned the child:—

March 31st, 1834.—Mary Lalley, æt. 26, delivered of a girl, still-born; third child. When she came in the os uteri was fully dilated; membranes projecting, and forming a tense bag during the pains. It was with difficulty the finger could reach the head, which was high up above the brim of the pelvis. When the liquor amnii came away, one or two coils of the funis were found presenting between the head and promontory of the sacrum. At all times the pulsation in the cord was but feeble, and during the pains, which were not strong, they ceased entirely. In order to give the child a chance of being born alive, Dr. Rigby thought it would be advisable to turn. Accordingly I introduced my hand slowly into the uterus. After passing the head I felt a hand, and then an elbow, and still higher up a foot, which I gently brought down. The patient suffered but little from this; but though I got the foot into the vagina, the head did not go up. Dr. Rigby then passed a fillet round the ankle, and pushed back the head, which required some force to make it retire. As the pains were inefficient, considerable extractive force was required to complete the birth. One arm came along with the head; the placenta quickly followed, with some large clots of blood, but the uterus soon contracted firmly.

April 1st.—In the early part of night had some difficulty in passing water; but after applying warm fomentations to the pubes, and steams of warm water to the pudenda, she passed it freely, and this morning feels easy and comfortable.

From the very feeble pulsations of the cord, even during the intervals of the pains, it was evident that as the head was so high, the only chance of saving the child's life was by turning. I rather suspect that I was in some measure the cause of the difficulty which Dr. Barr experienced in turning the child: having grasped one foot, and finding that the other was not so easily reached, I advised him to bring down the one which he had hold of; whereas, if the two feet had been brought down, the child would probably have been turned more readily.

Two cases of *placenta prævia* have occurred; in both the placenta was but partially attached, and in neither was it necessary to turn the child.

May 13th, 1834.—Mary Owen, æt. 30, out-patient, near her full reckoning, was seized with a considerable uterine hæmorrhage a week ago; it returned again the day before yesterday. Slight pains appeared this morning, and much flooding

followed. I saw her at 10 and 11 P.M.; os uteri dilated to about two inches; its anterior margin covered by the placenta; the head pressing on the os uteri. The discharge is now very slight; pulse full. I desired the midwife to keep her cool. The pains increased, and the labour followed naturally, without any further loss.

July 4th, 1834.—Anne Teeling, out-patient, reckons that she has still a month to go. Was surprised at 4 this morning by a profuse uterine hæmorrhage, which soaked through the bed; it continued for about half an hour, and made her feel very faint; it returned in an hour, but in less degree, and continued to dribble for some time. The midwife gave her an opium pill, and applied vinegar, &c. I saw her at 4 P.M.; os uteri nearly fully dilated; edge very uneven; margin of the placenta over its right and anterior edge; no discharge; head presenting in the third position; scarcely any pains; no liquor amnii; collected to distend the membranes. I gave her a dose of ergot of rye, with a little brandy, as she was extremely faint; the pains increased somewhat. Not having made water since 3 A.M., I drew off a small quantity of high-coloured urine, and gave her some ammonia, as the faintness continued. In the course of an hour a little liquor amnii began to distend the membranes. I ruptured them, and a considerable quantity escaped with every pain. The pains became stronger, the head descended, and a dead child about the eighth month was born. She recovered quickly.

In the first case nothing more was necessary than to let the labour go on, and not interfere; the head had effectually compressed the placenta, and the danger was passed. In the second the hæmorrhage had been so profuse, and the exhaustion was so great, that I feared she would not have sufficient strength to carry her through. It was an intensely hot day, and her relaxed half-fainting state added not a little to the disposition she had to perspiration. Besides the brandy and ammonia, I directed a little beef-tea to be made; and by giving her a tea-spoonful or two of it every few minutes, she revived considerably.

I well recollect thinking at the time of a passage in my father's work on Uterine Hæmorrhage, which applied remarkably to to this case. It is a part of the fourth case which he has recorded, and where the hæmorrhage and consequent exhaustion had been very alarming:—"By carefully attending (says he) to keep the room very cool, by preventing my patient from being the least stirred, and being myself her nurse, in giving her every few minutes small quantities of the coolest drinks, I prevented the discharge from increasing, and at the same time supplied as far as I could the waste of what she did lose, by the drinks she took being as nutritious as I could venture to give them without their being irritating."

[To be continued.]

COLLEGE OF SURGEONS.

LIST OF GENTLEMEN WHO RECEIVED DIPLOMAS IN SEPTEMBER, 1835.

James Plummer, Cirencester.
Edward Golding, Dublin.
William Tarleton, Hurley in Arden.
Wm. Alexander Gavin, Aberdeenshire.
James Williamson.
Wm. Barwick Clarke, Beckermont.
Arthur Benoni Evans, Hampstead.
Thomas Salmon, Barnstaple.
Frank Dobson Potter, Chipping Ongar.
Richard Goldstone, Bath.
Richard Beadon Ruddock, Stockland.
John Donald, A.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE II.

ON THE ACTION OF MEDICINES.

GENTLEMEN,—I proceed in this lecture to examine the action of medicines on the animal system.

We have two distinct classes of phenomena, one caused by the other, both of which may be denominated the *effects* of medicines; but in order to distinguish their order of sequence, we may term the one class the *primary*, the other the *secondary* effects. Purgatives, for example, excite a certain degree of irritation in the intestinal tube, in consequence of which they are sometimes useful in relieving morbid states in distant organs. The irritation, then, is the primary effect; while the beneficial influence on the previous disease is the secondary effect: the first has by several modern authors been termed *physiological;* while the second has, in contradistinction, been denominated *therapeutical.* In conformity with the usage of some of our best writers I shall adopt these designations, without, however, being satisfied that they are the best that could be applied.

Physiological or primary effects.—The physiological or primary effects of medicines, for convenience, may be divided into such as are *local,* or those that occur in the part to which the agent is applied; and into those that take place in distant organs, and which, by way of distinction, we denominate *remote* effects.

1. *Local effects.*—If you apply strong sulphuric acid, or the potassa fusa, to a living tissue, you will observe that the death of the part soon takes place,—various chemical changes being effected in it,—while the surrounding parts become inflamed, and tender to the touch. In this case, then, there are simultaneous chemical, physical, and functional changes; and we can readily believe the primary influence of the caustic to reside in its chemical properties. This constitutes one kind of local action.

Observe the effect which arises from the application of any of the substances called *irritants* to the body—that is, of substances which excite pain, heat, soreness, and even inflammation; as, for example, cantharides, savine, gamboge, tartar emetic, or alcohol. These agents alter the vital actions of the part, and occasion a series of physical and functional changes; but we have no evidence of any chemical influence. This may therefore be regarded as a second kind of local effect, where most of the phenomena seem referrible to some unknown influence of the medicine over the vascular system of the part; and we may even suspect that the nervous system is only secondarily affected.

But there is a third kind of effect, which can be arranged under neither of the before-mentioned heads, and of which we have a good example in the numbness produced by chewing aconite. The most powerful effect of this kind that I ever experienced is in the case of the *Aconitum ferox,* a plant growing in the kingdom of Nepal, and which is used by the natives as a poison, under the name of *Bish* or *Bikh.* At the request of Dr. Wallich I undertook a series of experiments on it, which have been published by him in the *Plantæ Asiaticæ rariores.* While the spirituous infusion of the root of this plant was evaporating, I applied a drop of the liquid to my tongue. Within ten minutes an intense numbness came on in the tip of the tongue, and in the lips, and was

followed by an affection of the velum and uvula, giving rise to a sensation as if these parts were elongated, or paralysed, and rested on the tongue. This latter effect left me in about a quarter of an hour, but the numbness remained for eighteen hours. In this case, then, it is fair to infer that the primary operation of the poison was on the nerves of the part. Other instances of a like nature might easily be quoted: I shall only name two—the numbness produced on the finger by applying the vapour of hydrocyanic acid to it; and the paralysis of the muscular fibres of the intestines from the application of the ticunas poison to them. Now although all changes in vital action are fairly referrible to physical or material changes, yet in the examples here offered we have no visible alteration.

2. *Remote effects.*—One of the most striking phenomena produced by medicines is the influence which they exercise over distant organs. Certain substances taken into the stomach have the curious property of exciting an increased flow of urine; others act on the salivary glands, and promote the salivary secretion. How do these phenomena take place? Do the medicinal particles actually pass through the body, from the stomach to the kidneys, or to the salivary glands; and are we to consider these cases as, in point of fact, examples of local action, or should we refer the primary influence to a change in the condition of the stomach, or of some other organ, in consequence of which an alteration is effected in the distant organ, by some mysterious and unknown agency which physiological writers have named *sympathy?* The facts which we have at present accumulated certainly are in favour of the supposition, that sometimes one, sometimes both, of these modes of operation take place. Let us consider them separately; and first,

Of the operation of medicines by absorption.—Under this head we have to examine the following questions:—

1. Do medicines pass into the blood, and are they transmitted from one part of the body to another?

2. If they do, what are the organs that absorb them—the veins, or the vessels called absorbents?

3. If medicines are absorbed, is it probable that the remote effects take place in consequence of the absorption?

4. If a medicine produce a remote effect, apparently in consequence of its passage into the blood, in what way is this peculiar influence exercised?

Let us examine each of these questions separately.

1. That medicines do pass into the blood, and are subsequently transmitted to some part distant from the one to which they are applied, is undeniable in a great number of instances. The facts in proof are of two kinds: *first*, it has been established by the experiments of Drs. Christison and Coindet, that four ounces of a solution of oxalic acid disappeared from the peritoneal sac of a cat in fourteen minutes; and there is no mode of satisfactorily explaining the disappearance of the fluid except on the assumption of its passage into the blood. *Secondly*, the medicinal particles have been repeatedly found either in this fluid, or in the secretions, or in both.

It is not necessary for me here to enter into the difficulties which have been experienced in detecting medicines in the blood: it is very easy to establish the fact of their existence in this fluid beyond the possibility of doubt, by experiments. Camphor, animal empyreumatic oil, musk, oil of turpentine, asafœtida, indigo, rhubarb, madder, gamboge, copper, lead, cyanuret of potassium, sulpho-cyanuret of potassium, sulphate of iron, sulphate of potash, cyanuret of mercury, chloride of barium, sal ammoniac, iodine, hydrocyanic acid, and alcohol, have been detected in it; and I must refer you to the writings of Tiedemann and Gmelin, of Flandrin and Magendie, of Grognier, of Cantu, and of Krimer, for further information on this point.

But the question is easily decided by experiments, which may be made on ourselves. It is admitted that the secreted fluids are separated from the blood; hence, if we detect medicinal particles in those fluids, we may fairly infer their previous existence in it. Let me, therefore, notice some of the substances that have been found in certain secretions:—

First, in the cutaneous secretion, mercury, iodine, sulphur, the odorous matter of musk, of garlic, and of onions, and other substances, have been detected.

Secondly, in the breath, several substances have been detected by their odour; for example, camphor, alcohol, ether, phosphorus, asafœtida, sulphur, the odorous matter of garlic, and of onions, &c.

Thirdly, in the milk. The milk sometimes acquires purgative properties, in consequence of the employment of purgatives by the nurse. Tonics, indigo, iodine, and madder, have also been distinctly recognised in it.

Fourthly, in the urine so many substances have been discovered, that it will be most convenient to exhibit them in a tabular form. The following is taken principally from the experiments of Drs. Wöhler and Stehberger, as mentioned by the late Dr. Duncan:—

SUBSTANCES WHICH PASS OFF BY THE URINE.

(A) Unchanged, or nearly so.

Salts.

Carbonate of potash.
Nitrate of potash.
Chlorate of potash.
Sulpho-cyanate of potash.
Hydro-sulphuret of potash.
Ferro-cyanate of potash (in 66 minutes.)
Silicate of potash.
Tartrate of nickel and potash.
Borax.
Muriate of barytes.

Colouring Principles.

Indigo } (in 15 minutes.)
Madder }
Rhubarb (in 20 minutes.)
Gamboge.
Logwood (in 25 minutes.)
Red radishes.
Mulberry.
Black cherry (in 45 minutes.)
Cassia fistula (in 55 minutes.)
Elder rob (in 75 minutes.)

Odorous Principles, somewhat altered.

Oil of turpentine.
——— juniper.
Valerian.
Saffron.
Asafœtida.
Garlic.
Castoreum.
Opium.
Narcotic principle of Amanita muscaria.
Asparagus (*Cullen.*)

Other Matters.

Astringency of Uva ursi (in 45 minutes.)
Oil of almonds (*Bachetoni.*)

(B) In a state of Combination.

Sulphur, as sulphuric and sulphuretted hydrogen.
Iodine, as hydriodic acid.
Oxalic, Tartaric, Gallic (in 20 minutes), Succinic, Benzoic acid } Acids, appear in combination.

(C) In a Decomposed State.

Tartrate, Citrate, Malate, Acetate } of potash, or soda, are changed into the carbonate of the same alkali.
Hydro-sulphuret of potash changed, in a great measure, into the sulphate of potash.

I have only to remark respecting this table, that one of the easiest substances to experiment with is nitre, which may be readily recognised by dipping a piece of paper into the urine and drying it, when it will be found to deflagrate like touch-paper. If the accounts published respecting the *Amanita muscaria* (fig. 7) be correct, its effects are most extraordinary. A variety of this fungus has a powerful narcotic or rather inebriating effect; and that the active molecules do get into the blood is proved by the fact of the urinary secretion being impregnated with them, and thus possessing an intoxicating property; and we are told that the inhabitants of the north-eastern parts of Asia use it for this purpose. A man, for example, may have intoxicated himself to-day by eating some of the fungus; by the next morning he will have slept himself sober; but by drinking a tea-cupful of his urine he will become as powerfully intoxicated as on the preceding day. "Thus," says Dr. Greville, on the authority of Dr. Langsdorf, "with a very few *Amanitæ*, a party of drunkards may keep up their debauch

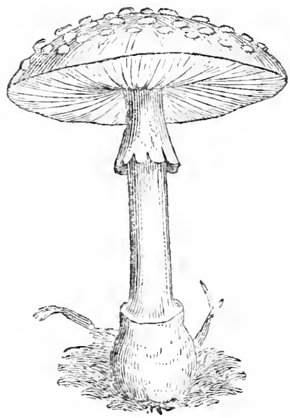

Fig. 7.—*Amanita muscaria.*

for a week;" and "by means of a second person taking the urine of the first, a third of the second, and so on, the intoxication may be propagated through five individuals."

To the facts now stated in proof of the absorption of medicinal agents, I may add the discovery of various substances in the solids of the body, such as the colouring matter of madder in the bones, copper and lead in the liver, mercury in various tissues of the body, &c. I cannot, however, help noticing here the hypothesis of Dr. Percival, more especially as it is adopted by Dr. Chapman, an American author on Materia Medica. He supposes that those medicines which, when administered by the stomach, can be detected in the secretions, do not exist in their original state in the blood, but are reproduced in the secreting organs. Without entering into all the inconsistencies of this hypothesis, I may mention that the subsequent discovery of so many substances in the blood is quite sufficient to overturn it.

2. Do the veins or the lacteals absorb medicinal particles? The ancients, unacquainted with the lacteal and lymphatic vessels, attributed to the veins the absorption of solids and liquids from the surfaces of the body. The truth of this doctrine, however, was called in question by Dr. William Hunter and Monro secundus; and their opinions were supported by the experiments of Mr. John Hunter. A change consequently took place in the opinions of physiologists, and absorption was presumed to be exclusively effected by the lacteal and lymphatic vessels. The subsequent experiments of Magendie, of Flandrin, and of Tiedemann and Gmelin, have, however, proved that the veins do absorb medicinal substances, and have rendered it highly probable that the lymphaties and lacteals do not.

Tiedemann and Gmelin administered a variety of colouring, odorous, and saline substances to animals, mixed with their food, and afterwards examined the state of the chyle, and of the blood of the veins of the alimentary canal. The *colouring* substances employed were—indigo, madder, rhubarb, cochineal, litmus, alkanet, gamboge, and sap-green; none of them could be detected in the chyle, but some were found in the blood and urine. The *odorous* substances used were—camphor, musk, spirits of wine, oil of turpentine, Dippel's oil, asafœtida, and garlic: they were for the most part detected in the blood and urine, but none were found in the chyle. The *saline* substances tried were—acetate of lead, acetate and cyanuret of mercury, chloride and sulphate of iron, chloride of barium, and ferro-cyanuret and sulpho-cyanuret of potassium. A few of these were detected in the chyle, and most of them in the venous blood and urine. From these experiments we may conclude, that although saline substances occasionally pass into the chyle, odorous and colouring matters do not; all, however, are found in the blood.

Magendie performed a striking experiment, with the view of settling, if possible, the question of the venous or lymphatic absorption of medicines and poisons. He divided all the parts of one of the posterior extremities of a dog, except the artery and vein, the former being left entire, for the purpose of preserving the life of the limb. A portion of the *Upas tieuté* was then applied to a wound in the foot: in the short space of four minutes the effects of the poison were evident, and in ten minutes death took place. To the inferences drawn from this experiment, however, several objections have been stated: first, the exhibition of opium, to diminish the pain of the operation, has been said to vitiate the whole of the experiment; secondly, the coats of the arteries and veins contain lymphatics, by which absorption might be carried on; and thirdly, as the poison was introduced into a wound, the poison might have combined with the blood, and have rendered it deleterious, without the process of absorption taking place. The first two of these objections have been obviated. Some years since I assisted my friend Mr. Lloyd, assistant-surgeon of St. Bartholomew's Hospital, in performing an analogous experiment, using *Strychnia* instead of *Upas tieuté*, and not administering opium: death took place in twelve minutes. In a second experiment, Magendie severed the artery and the vein, and reconnected them by quills, so as to preclude the possibility of absorption taking place by the lymphaties of these vessels: the effects were the same.

We may, then, I think, fairly conclude that the absorption of medicinal particles is effected by the veins. I do not think it necessary to enter into any discussion as to how these vessels carry on this function, and whether medicinal particles enter by what have been called absorbing mouths, or by imbibition through the coats. The hypothesis of the latter mode of transit has been ably supported by Magendie; and to his lectures, published in the Lancet of last year (1834), I beg to refer you for the numerous and striking facts which he adduces in favour of his own view. If his hypothesis of imbibition be correct, absorption must no longer be regarded as a vital, but merely a physical action. The principal objection to this opinion is the difficulty of accounting for the absorption of the particles of solid substances.

3. The next point to be examined is the probability or otherwise of the remote effects of medicines being produced by the absorption of the medicinal particles; for it does not necessarily follow that because certain active substances are found in the blood, their action on the system must be a consequence of their transit.

Mr. Travers, in his "*Further Inquiry concerning Constitutional Irritation,*" points out very forcibly the analogy to be observed between the effects of severe injuries and those of poisons operating rapidly upon the system (thus a punctured wound sometimes produces tetanus, so does strychnia); and he concludes that the *modus operandi* in the two cases is identical. As, in cases of injuries, there can be no absorption, so neither is there in cases of poisoning. But no injuries of remote parts that I ever heard of have produced the salivation which is caused by the use of mercury, or the affection of the urinary organs which cantharides are capable of exciting. It must, I think, be admitted that our opinion, whether for or against the operation from absorption, must be founded on probabilities, since the subject is incapable of actual demonstration or proof. I confess I cannot help thinking, that in a considerable number of cases the alteration of functions produced by poisons and medicines is the result of absorption. Let us consider *seriatim* the circumstances in favour of this opinion.

In the *first* place, we know that no organ in the body can perform its functions without a proper supply of blood; and we also know that alterations in the quality of this fluid are attended with corresponding alterations in the actions of the system; in proof of which I may refer to scurvy brought on by improper kinds of food (as the long-continued use of salt provisions.) We are, therefore, naturally led to suspect, *à priori*, that the passage of medicinal molecules (especially those of known activity) into the blood, and the circulation of them, would be attended with some functional disorder. This suspicion becomes stronger and more valid when we try the effect of injecting substances into the veins. We find tartar emetic excites vomiting; castor oil, purging; opium, narcotism.

Secondly, it seems that the effects of some medicines are modified by circumstances that influence absorption, and therefore we are naturally led to presume a mutual relationship. Thus the activity of a medicine is not uniform when applied to different parts of the body. Nux vomica, for example, is most energetic when applied to the pulmonary surface, less so when swallowed, and still less when applied to the skin; and the same remark applies to opium. Now the faculty of absorption, or of imbibition, as Magendie calls it, does not take place with equal intensity in all tissues. Certain physical conditions (viz. a fine and delicate structure, and great vascularity) enable the pulmonary surface to absorb or imbibe with extreme rapidity: in this respect, indeed, it is not equalled by any tissue of the body. Hence, then, if we assume that nux vomica and opium act by becoming absorbed, we can easily comprehend why these substances are so energetic when applied to this part. The membrane lining the alimentary canal absorbs with less facility than the pulmonary membrane,—which may be accounted for by the less extent of surface in contact with the medicine, by its less vascularity, and by its being covered, in some parts at least, by an epidermoid layer, and in all its parts by mucus, which to a certain extent checks absorption. We see, then, the reason of the less activity of the above-mentioned poisons, when applied to the alimentary membrane, if we admit their operation by absorption. The cutaneous surface, lastly, being covered by an inorganic membrane (the epidermis), does not possess the same physical faculties for absorption met with in either of the foregoing tissues; and hence the comparative inertness of medicines when applied to it. In fact, it is only by the long-continued application of these agents to the skin that we are enabled to affect the general system; and that the obstructing cause is the epidermis, is shown by the facility with which the system may be influenced when this layer is removed, as has been proposed and practised by Lembert and Lesieur, constituting what has been denominated the *endermic* or *emplastro-endermic* method of treating diseases: of this method I shall have occasion to speak hereafter.

Another circumstance tending to prove some connexion between the activity of a medicine and its absorption is, that the effect of many medicines is in proportion to their solubility. Arsenic and morphia are both more energetic in solution than in the solid state. Now liquids (particularly those miscible with the blood), are much more readily absorbed than solids, and therefore, by admitting the absorption of medicines, we have an easy explanation of the fact. In the treatment of many cases of poisoning we endeavour to take advantage of this principle, and by rendering substances insoluble, diminish their activity, or render them quite inert. Thus the antidote for the salts of lead, or of barytes, is a sulphate, the acid of which forms an insoluble salt with either of the bases (lead or barytes.). Gallic acid (or astringent infusions which contain it) is

for the same reason found useful in cases of poisoning by vegetable substances whose active principle is an alkaloid; and we employ carbonate of lime as an antidote for oxalic acid, to render this substance incapable of absorption.

We may add another argument to the above, and which, like them, is capable of practical application. Magendie asserts, as the result of experiments, that plethora uniformly retards, and depletion as constantly promotes, absorption. If, therefore, we wish to promote this function, we have a ready means of doing so in blood-letting. Thus, every surgeon knows that one powerful means of promoting the action of mercurials on the mouth is to abstract blood. And the same principle leads us to be very cautious in bleeding while a poisonous dose of opium or any other narcotic is in the stomach. Nay, in theory, the best means of preventing the operation of narcotic and other poisons that act by becoming absorbed, would be to throw a quantity of warm water into the veins. Magendie tried this on animals, and found it successful.

Thirdly, the experiment of Magendie, already related, of applying the *Upas tieuté* to the leg of a dog, connected to the body only by two quills, is another argument in favour of the operation of medicines by absorption.

The *last* argument which I shall adduce is, that some poisons, as prussic acid, are equally active when applied to the legs of an animal in whom the spinal marrow has been divided. In this case the effect of the poison could not be the result of its action on the nerves of sensation and voluntary motion. But it is said the division of the lumbar spine does not prevent the action of poisons, because it does not destroy the action of the sympathetic system, the nervous branches of which are distributed to the lining membrane of the blood-vessels. I am aware that it is an experiment liable to objection; but, on the whole, it is certainly favourable to the opinion of the operation of poisons by absorption; more particularly when we bear in mind that the motion of the blood is necessary to the action of the poison; for if the circulation of a part be obstructed, the poison will no longer act.

Taking into consideration, then, all these arguments, I can come to no other conclusion than that it is in the highest degree probable that the remote effects, of some substances, are produced in consequence of their absorption. I cannot admit this position to be at all invalidated by the experiments of Messrs. Morgan and Addison. Indeed, these physiologists do not deny the fact that poisons *may* enter the blood-vessels, and, in consequence, produce their poisonous effects on the system, but they deny the absolute necessity of this process. "It will be seen," say they, "that we are not opposed to the theory of venous absorption, but to the theory which would associate with it the *absolute necessity* for the admission of a poison into a vein, as a cause, and a sole cause, of its effects upon the body."

4. It being admitted, then, that certain medicinal or poisonous agents do get into the blood, and that when in this fluid they exercise a powerful influence over remote parts of the body, I proceed now to examine in what way this influence is communicated to distant organs. In the examination of this question, we meet with so many difficulties inseparably connected with the subject, that we cannot but acknowledge that any conclusion our reasoning may lead us to adopt, must be in the highest degree problematical. Viewing the question theoretically, we see three ways, by one or more of which a distant organ may become affected by the passage of medicinal molecules into the blood; namely—

(*a*). The medicinal particles circulating with the blood are brought into contact with all the tissues of the body, and thus an organ far distant from the stomach may be affected by local contact with the active molecules.

(*b*). Or we can conceive the possibility of the medicinal molecules making some impression on the lining membrane of the blood-vessels, and which, by sympathy, may be extended to remote parts.

(*c*). The properties of the blood may undergo some change by the contact of this fluid with the molecules of medicines, and the different organs of the body may have their actions or functions materially affected by receiving thus a vitiated blood.

Let us examine each of these supposed modes of operation separately, and endeavour to determine which has the greatest probability.

(*a*). It is the general opinion of physiologists, that after medicines or poisons have got into the blood, they are carried, in the ordinary course of circulation, to the heart, and from thence to the lungs. Here the blood undergoes certain chemical changes, and probably loses part of the foreign particles; at least this appears to be the case with respect to the molecules of certain odorous substances. The blood, still impregnated with medicinal particles, is returned to the heart, and from thence is transmitted to all parts of the system. In their passage through the tissues of the different organs, it is presumed that these particles act on one or more parts which are endowed with a peculiar susceptibility to their influence. Thus the opiate par-

ticles are supposed to exert a specific influence on the cerebral tissue; strychnia is thought to act on the tissue of the spinal marrow; mercury on the salivary glands, and so on. The molecules are supposed to be ultimately got rid of by the excretory organs. On this supposition, then, the blood is merely the "vehicle of introduction."

It must, however, be admitted, that this very plausible theory cannot be satisfactorily proved. We may adduce several arguments in favour of the opinion that medicines and poisons are conveyed to the parts on which their remote action is principally observed, but absolute proof or demonstration cannot be offered: our facts merely prove the passage of medicinal particles into the blood, and the affection of the remote organs; but the link which connects the two phenomena cannot be, or at least has not yet been, shewn. The strongest argument that, in my opinion, can be brought forward in favour of this theory, is, that the molecules of certain medicines may be detected in some one or more of the excreted fluids; and at the same time we find that the functions of the organs secreting or excreting these fluids have become influenced by the medicine. Now the simplest, and, therefore, the most plausible, explanation of these facts, is, that the molecules, in passing through the organ, acted on its tissue, and thus gave rise to the functional disorders. Let us select an example or two.

When nitre is exhibited, diuresis is frequently produced, while the salt may be recognized in the urine. The alkalies also usually have some diuretic effect, and at the same time alter the condition of the urine, either neutralizing the free acid, or even rendering this secretion alkaline. The oil of turpentine, in like manner, is supposed to produce its diuretic effect by local contact with the kidneys; for the urine acquires by its employment a violet odour. We are incapable of offering arguments of this kind in a large number of cases, either because the active principles of medicines are not easily detected, or because the part on which they act is not a secreting organ.

Thus, if it be true that strychnia acts on the spinal marrow by local contact, we cannot prove its presence in this part for the reasons just mentioned. We see, then, that this theory, though plausible, cannot from the nature of the evidence be easily proved. Is there any thing improbable in it? Can any arguments be adduced which are adverse to it? I am bound to acknowledge that there are. Many substances which have been swallowed may be detected in different secreted fluids, although they exercise no power or action over the secreting organs. Thus if a dose of rhubarb be swallowed, the colouring particles may be detected in the urine, although this secretion does not appear to be otherwise altered; and therefore it may be said that in those cases where the quantity of the secretion is affected, we have no right to infer that it depends on the passage of the medicinal particles through the secreting vessels. This objection, however, deserves but little attention, inasmuch as we know that the susceptibility of the same part is not the same to all medicines; for it is not every medicine which produces vomiting when applied to the stomach.

It has also been said that this theory of medicines "being conveyed by the circulation to particular parts, is utterly gratuitous, and no less improbable."—"What intelligence," says an American writer, "directs them, in this voyage of circumnavigation, to the port of destination; and how, on their arrival (admitting it to happen), are they separated from the great mass of fluids in which they are enveloped?" It is not supposed, on this theory, that medicines are *conveyed to particular parts;* we presume that the medicinal molecules are *conveyed to every part* of the body in which the blood circulates, but that certain parts only are susceptible to the influence of these particles. But, then, it may be replied, how is it that particular parts only are affected, since medicinal molecules are in contact with every part? We do not pretend to account for this circumstance. Every one is familiar with the fact that carbonic acid may be applied to the stomach in large quantity with impunity; whereas, if taken into the lungs, it acts as a narcotic poison. The urine has very little effect on the bladder, but if introduced into the cellular tissue, it gives rise to violent inflammation.

I have already alluded to another objection to this theory—namely, that injuries sometimes produce the same symptoms as poisons. But it must be recollected that in a large number of instances injuries do not produce the same symptoms; and in those cases where the effects of the two are analogous, I see no difficulty in assuming that there are two modes of affecting the nervous system: mechanical or other injury to the nervous fibrils; and the circulation of poisonous molecules in the cerebral vessels.

The most important objections that have been advanced against the operation of medicines through the circulation, by local contact with the tissues, are those founded on the experiments of Messrs. Morgan and Addison. Of all their expe-

riments, the following are, I conceive, the strongest against the theory under examination:—

The jugular vein of a full grown dog was secured by two temporary ligatures; one of which was tied round the upper, and the other round the lower part of the exposed vein. The vessel was then divided between these two ligatures, and the truncated extremities reconnected by means of a short brass cylinder or tube (fig. 9), within which was placed a portion

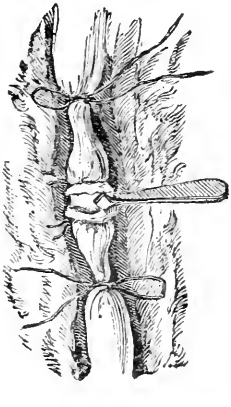

FIG. 8.

FIG. 9.

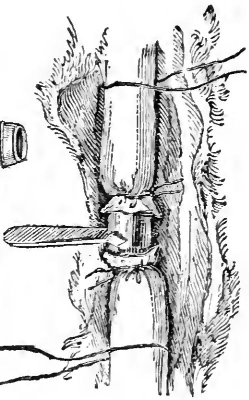

FIG. 10.

of woorara, of the size of a grain of canary-seed (fig. 8). Both the temporary ligatures were then removed (fig. 10), the accustomed circulation through the vessels was re-established, and in forty-five minutes the animal dropped on the ground, completely deprived of all power over the muscles of voluntary motion: in two minutes, convulsions and respiration had entirely ceased. This result was to be expected, whatever theory be adopted.

In another experiment, two temporary

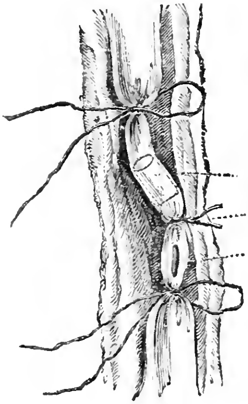

FIG. 11.

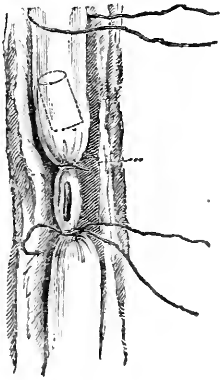

FIG. 12.

ligatures were applied to the jugular vein, as in the former case. A cylinder of quill containing a little woorara was then introduced into the vein between the two ligatures; another ligature was then applied (fig. 11), and the upper temporary ligature removed (fig. 12). In the space of 108 seconds after the removal of the ligature, the animal dropped in convulsions, as in the former case, and expired in 3¼ minutes. Now, in this experiment, the direct entrance of the poisoned blood into the heart, &c. was prevented by the lower ligature: hence, if this poison operated by contact with the brain, a greater length of time was necessary for its effects

to be produced; inasmuch as the circulation was no longer going on through the trunk of the jugular itself, and therefore if the poison acted by cerebral contact, it must have got into the system by the vessels of the vein.

The results of this experiment, it must be admitted, are somewhat difficult to account for, on the supposition that the woorara influences the brain by local contact, though they are not absolutely incompatible with it. Before, however, we can attach much weight to the experiment, it ought to be repeated several times, in order to determine whether the results obtained by Messrs. Morgan and Addison uniformly occur. It is necessary, as Dr. James Blundell has truly observed, "not to draw conclusions hastily from a few experiments, but, on the contrary, to multiply them as much as may be, since it is by performing the same experiment repeatedly that important exceptions are sometimes ascertained." But admitting that this experiment was performed with every attention to accuracy, and that the results obtained were correct, the most that can be inferred is that the woorara may disorder the cerebral functions without local contact with the brain On this supposition, then, woorara will not be peculiar in its operation; for concentrated hydrocyanic acid is presumed to act in a similar manner. We have no right to infer, because one poison (and that very imperfectly known) is presumed from one experiment not to act on the brain by local contact, that therefore no other poison can act thus. I cannot see the absurdity of admitting that the brain may be influenced in two ways—by local contact and by the medium of the nerves; I cannot admit that "all fair analogy forbids the conclusion." I cannot forbear here quoting an observation made by Mr. Travers on this point, more particularly as he is a supporter of the views of Messrs. Morgan and Addison. "But though it has been fairly argued that it is unphilosophical to admit two modes of explaining a phenomenon when one suffices, it cannot be denied that absorption by the blood may extend to the disintegration of it, and its incapacity of so acting on the nerves as to entertain life, any more than that it may be the vehicle of a subtle poison, which, upon reaching the sentient nerve, is instantly diffused over the nervous system, and puts a stop to its power."

The following experiment, related by Messrs. Morgan and Addison, appears to me to be of less weight than the one just mentioned. By the aid of a double brass tube (figs. 13 and 15) they established a complete double circulation between the carotids of a poisoned and of a sound dog, by connecting the lower and the upper ends of the divided arteries in both animals, so that each supplied the brain of the other with the portion of blood which had previously passed through the carotid artery to his own (fig. 14); and consequently the poisoned dog, in this case, received from the unpoisoned animal a supply of arterial blood equal to that with which he was parting. One of the dogs was then inoculated with a concentrated preparation of strychnia, which had been found, upon other occasions, to produce death in these animals in about three minutes and a half. In three

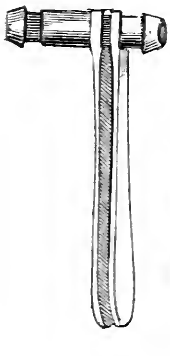

Fig. 13.

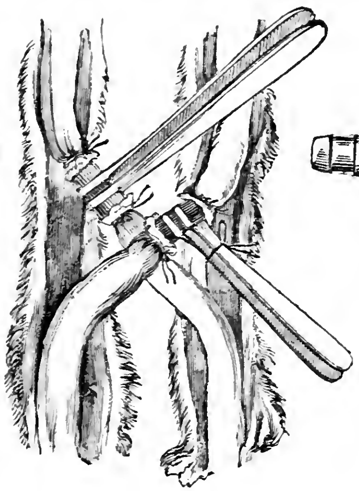

Fig. 14.

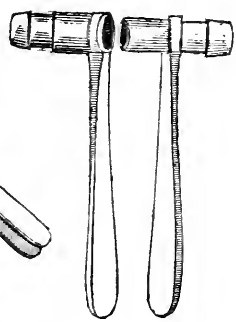

Fig. 15.

minutes and a half the inoculated animal exhibited the usual tetanic symptoms which result from the action of this poison, and died in a little less than four minutes afterwards—viz. about seven minutes from the time at which the poison was inserted; during the whole of which time a free and mutual interchange of blood between the two was clearly indicated, by the strong pulsation of the denuded vessels throughout their whole course. The arteries were next secured by ligature, and the living was separated from the dead animal; but neither during the operation nor at any subsequent period, did the survivor shew the slightest symptoms of the action of the poison upon the system.

The inference which has been drawn from this experiment is, that the arterial blood of an animal under the influence of poison is not poisonous. It appears to me, however, that this is not a necessary inference from their experiment; and as it is opposed to numerous facts, it requires careful examination ere we admit it.

Even if the blood of the inoculated animal had been really poisoned, the effect on the second animal would have been comparatively slight: for if the circulation of blood through the tube had been as free as through the artery, (which may be fairly doubted,) the second animal could receive little more than one-fourth only of the quantity sent to the brain alone, and, therefore, but a small part of the whole circulating blood in which was diffused the poison. Now as it is presumed that strychnia acts on the spinal marrow (not on the brain) by local contact, the blood thus sent to the brain would have to go through the usual route of the circulation before it could reach the medulla; and it is not too much to suppose, that during this transit some portion of the poison might be decomposed, or thrown out of the system, before it could reach the spinal marrow; and even if this were not the case, this organ could only receive a small portion (viz. that sent by the spinal arteries) of the poison contained in the system. This will, therefore, explain why a poison thrown into the arteries acts less powerfully than when thrown into the veins, unless it be the arteries supplying the parts on which the poison acts.

These reasons, then, lead me to doubt the correctness of the inferences which have been drawn from the ingenious experiments of Messrs. Morgan and Addison. When to these we add that Vernière found the blood of dogs killed by nux vomica was poisonous to leeches, and also to another dog when thrown into a vein, I think I am justified in stating that further experiments are required to disprove the theory of the operation of poisons by local contact.

Mr. Travers, in noticing the different results obtained by Vernière and Messrs. Morgan and Addison, says, that "if it be inquired why the poisoned blood concentrated below a ligature, and transferred into the vein of a healthy animal, proves destructive, while the blood of their common circulation affects only the one of the two animals which is the subject of the inoculation, the answer is obvious—that either the mechanical impulse fails, or the activity of the poison is exhausted before, in the latter case, it reaches the second animal." This admitted uncertainty, then, as to these experiments to which so much importance has been attached, proves, I think, that not one of them can be regarded as an *experimentum crucis.*

(*b.*)—It has been presumed by Messrs. Morgan and Addison, that when poisons pass into the circulation, and in this way affect the system, the effects result from the impression made upon "the sensible structure of the blood-vessels." And Mr. Travers says that the sentient properties of the lining membrane of the blood-vessels "is pre-eminently adapted to be impressed by the introduction of foreign substances or alterations in the condition of the blood:—their nerves are derived from the sympathetic or organic nervous system." Though I do not think it at all improbable that some medicines may act when they get into the circulation in the manner here assumed, yet further evidence is wanting on this point; for, as Bichât observes, sympathies in veins, like those in arteries, are very obscure, and we are but little acquainted with the influence which the tissues of these vessels may possess over other tissues.

(*c.*)—The operation of every medicine was formerly referred to the effects which it produced in altering the physical or chemical condition of the fluids, or, as they were termed, the *humors* of the body. To this doctrine of *humorism* succeeded that of *solidism*; in which the effects of all medicines were explained by alterations in the solids. These notions are now giving way to a kind of compound doctrine of *humoro-solidism*; and it is presumed that diseases are referrible sometimes to the blood, sometimes to the solids; and therefore that the operation of medicines may be either on the one or the other. It is possible that modifications in the qualities of the chyle, or of the lymph, may sometimes be the proximate cause of disease; but on this point we have no accurate information to guide us. No facts are known which demonstrate that the action of medicines and of poisons is primarily on the blood, although several circum-

stances favour the probability of such an opinion. We know that in many diseases the properties of the blood are altered; that in some cases the blood of a poisoned animal acquires poisonous qualities; and that by the use of poisons, medicines, or particular kinds of diet, we may alter the properties of the blood, and produce certain diseased states. It may, indeed, be said, that in these cases the alteration in the qualities of the blood is the consequence of the altered action of the solids; but when we bear in mind that the solids are nourished by the blood, and that they cannot support life without it, we cannot but admit that they must be influenced by the different conditions of this fluid.

Physiology, then, leads to the conclusion, that while alterations of the solids may be succeeded by alterations of the blood,—modifications of the blood may be succeeded by modifications of the solids; and, as an able continental writer has remarked, it is as hypothetical to assert that all medicines and poisons act primarily on the solids, as to assert that they all act on the blood: there is as much physiology in the one hypothesis as in the other.

ON THE

CHOLERA OF NORTH AMERICA.

To the Editor of the Medical Gazette.

SIR,

As the subject of Cholera still courts inquiry, I send the inclosed, if suitable, for insertion in your journal.—I am, sir,

Your obedient servant,

G. FARR,

M.R.C.S. & L.S.A.

Assist.-Surg. Ordn. Med. Depart.

Woolwich, Sept. 22, 1835.

In treating the subject of spasmodic cholera, more particularly as it appeared in the northernmost parts of America (where, however, its symptoms and appearances principally varied in the degree of their malignity, as compared with those exhibited in other parts of the world), my sole intention is to show the nature of its development, as influenced by the various modes of practice which were instituted to combat it; and to state what was finally deduced from these various means, by the majority of practitioners, as the most successful methods of treatment. In this attempt, I hope I may be excused in occupying the place of other matter, when it is considered that however desirable it may be to obtain a just estimate of the pathological nature of the disease, yet, as it has been of so fatal a character, it is the proper mode of treatment that we particularly want to see; and, therefore, he appears not to deserve ill who is willing to give an account of his own, especially when it has been more or less approved by other members of the profession with whom he has acted in concert. I may be permitted to presume, also, that the vastness of the field in which I was employed in those years, which will ever be memorable in North America—viz. 1832 and 1834, when the mortality from spasmodic cholera far exceeded that produced by the same disease in any other part of the world, is not the less a recommendation to my observations, having had the immediate charge of several hundreds of cases of more or less perfectly formed cholera, and having travelled upwards of a thousand miles through various districts where it either was, or had been raging; and, moreover, having personally witnessed and performed nearly every thing which I am about to state, which, it must be kept in mind, relates almost entirely to Canada, although there are few observations which will not apply, with nearly equal force, to the state of things at the same time in the adjoining republic.

Premonitory Symptoms.

I shall without farther remark commence with the disease itself, and leave any cursory observations till afterwards. There was, as in India and other places, a regular train of premonitory symptoms, more or less perfectly formed, in most cases; but in some it can hardly be said that there was any; for when a man who was about his ordinary business, apparently in tolerable health, suddenly fainted in the street, then vomited a little, turning cadaverous, and dying in half or three-quarters of an hour, without any purging at all, it cannot practically be said that he had any premonitory symptom; neither do any of these observations apply to such a case, as restorative means are here quite out of the question.

The person affected, then, with premonitory symptoms, felt an universal languor; impatience of interruption; pettishness, and dejection of spirits; loss of appetite; or, if the food was taken, it

remained like a heavy load at the pit of the stomach; some slight thirst, and other symptoms of indigestion, attended by giddiness of the head, and sometimes swimming of objects before the eyes; chills, and occasional numbness in different parts of the extremities; perhaps constipation of the bowels; in other cases something like the reverse; but not diarrhœa to an extent which I shall presently term the first stage of the disease.

I will not at present touch on treatment or remedies, but will go through with the progress of the disease, which, in a great majority of cases, is so systematic and methodical in its symptoms, as to allow of being divided into distinct stages, which, by the way, has been done by several writers, particularly Kennedy, although I shall take the liberty of observing a slight deviation or two from his rule. There will often, of course, be a difference in the real appearance of the disease and in its representation on paper. In the latter case we may, for the purposes of clearness and elucidation, have recourse to distinctive marks, and regular lines of difference in the symptoms, duration, and other circumstances of it, in order to see and understand its character better; but sometimes symptoms, and even stages, are blended together in the patient's case; and hence the value of experience, which, being attained, enables us still to treat it, in some measure, according to regular principles, although, at the time, we may be obliged to divest each division of its abstract grade.

Invasion of the Disease.

Under the head of the first stage of the disease it will be right to say a few words upon those articles of diet which, in all countries, act so perniciously upon the alimentary canal in hot weather, and which, owing to the excessive contrast of the summer and winter, together with the sudden cessation of the one season and the arrival of the other, act upon these organs in a most intemperate degree in America. Fish, aqueous fruits and vegetables, hard salted provisions, fermented liquors, ardent spirits, acids, and iced-water, are only a few of the articles which compose this almost indefinite tribe. These things in most countries, perhaps, act by producing diarrhœas and common cholera, both of which are produced in Canada, especially in the summer months, to a somewhat serious degree, from irregularities of diet, and also from the use of the water of the rivers, which is very strongly impregnated with lime and magnesia. Spasmodic cholera, then, happening to be epidemic, and diarrhœa being one of its common precursors, it is easy to imagine what facilities of dissemination it acquired: accordingly, the first stage of the disease commonly had marked symptoms of diarrhœa; these, however, were attended by some peculiarities. Upon loss of appetite, restlessness at night, slight thirst, heaviness and pain of the head, united with some other symptoms of the premonitory kind, would succeed an increased number of evacuations from the bowels, preceded by pain, and attended by tenesmus and tormina. These evacuations were characterised by nothing like bile; they were a little frothy and viscid, but nearly altogether composed of a disagreeable, clay-coloured or muddy water; at the same time very offensive. If this was allowed to go on for a few hours, numbness and tingling of the limbs supervened, attended by coldness, and in a short time by slight cramps. There is now a somewhat dark areola about the eyes and mouth; and sometimes at this early period the voice considerably alters, becoming both hoarser and weaker. The evacuations continue to be more watery, and prostration of strength rapidly ensues. Here, then, congestion has commenced, indicated by the more particular coldness of the limbs, the headache, and also by the state of the pulse, which is flagging.

The next, or second stage of the disease, is generally ushered in by the first, in a more or less developed state; sometimes, however, it advances immediately upon the patient, without any precursor of consequence. Here our attention is immediately awakened by symptoms of violent headache, great pain darting through the stomach and bowels, vomiting of a semi-transparent watery fluid, and constant stools of what has most aptly been called rice water. The fœtor of the stools is peculiar; and there is an offensive or deadly odour exhaling from the body, which odour is also peculiar and characteristic. If this state of things is allowed to proceed, the cramps which had commenced in the extremities increase in a short time to violent spasms, travelling on-

wards towards the central organs of life. The abdominal muscles and diaphragm become implicated, and a peculiar painful sensation, apparently sympathizing with these spasms, runs through the brain. The pulse soon becomes nearly imperceptible, the body cold, and the skin wrinkled about the hands and feet; the countenance sinks, and becomes cadaverous; the face wrinkled and shrivelled; the eyes sunk and cast upwards; the tongue becomes cold, and the thirst much more considerable; the voice hoarse, sunk, and guttural. Anxiety, great restlessness, fear, and occasional cries (sometimes vehement) characterize this state of things.

We find but too often that all our efforts to arrest the disease in this stage are futile, and with the most astonishing rapidity and vehemence this terrible malady advances steadily to the last stage. Now, then, the spasms put on the most violent form, particularly attacking the heart. The shrieks of the patient are sudden and piercing; the restlessness extreme; the pulse becomes quite imperceptible; the face and extremities much more discoloured, having a dingy blue hue, which sometimes increases to an alarming extent, appearing the colour of black-lead shaded with bronze. The countenance is horribly sunk; the eyes ghastly; the odour from the body very deadly; the feet and hands extremely soddened and shrivelled; the whole body is covered with a cold, clammy, watery fluid; the thirst is most intolerable, and the voice very much sunk, hoarse, and sepulchral. The dejections continue as frequent and copious for some time, and, in the majority of cases, a diminished vomiting continues. It is to be regretted that when the symptoms have gained this preeminence it almost invariably happens that the patient shortly sinks into perfect collapse: his appearance is then almost that of a dead person; he breathes in a hurried but feeble manner; his eyes are not quite closed; the cold sweat lies upon the surface of the body in large drops; the fæces pass involuntarily for a short time, and then cease; the vomiting ceases. The patient finally dies quietly, evidently possessing a correct knowledge of all that has taken place, and sensible of the presence of surrounding objects.

Sometimes the disease made its attack upon the patient in a different manner from that above recited (although not so suddenly as in those cases mentioned in the early part of this paper, where the patient might have been pursuing his ordinary occupation at the time of attack and almost immediate death); instead of coming on in a regular way, and proceeding through a regular series of symptoms and stages, its peculiar virulence was almost immediately developed amidst a confusion of symptoms of all kinds, which, after having proceeded with violence for a very limited time, were succeeded by perfect collapse. This is designated by Kennedy as the "rapid type;" and a more appropriate name could not have been given it.

There are a few other circumstances connected with this progress, and one or two anomalies. From about the time of the invasion of the second stage there is no secretion of urine; and I may add, that however violent the cries of the patient may be, whether male or female, you never observe tears, or any excretion from the nose. I do not think the secretion of saliva went on: although I never observed the tongue to be either remarkably white, or furred, yet I have seen both these symptoms in a moderate degree in different patients; but in the majority of them the tongue was nearly clean. It must be especially noted, too, that one of the earliest distressing symptoms is pain at the epigastrium, as noted by Mr. Annesley.

In patients who recovered, some trouble was occasioned in healing excoriations about the rectum, apparently arising from acridity in the matters passed from the intestines. A peculiar appearance sometimes takes place in the eye some hours before death; it consists in an extravasation, or ecchymosis, under the conjunctiva, upon the sclerotic coat, and, in general, has the appearance of a dark or black-coloured bar running transversely across the eye, below the cornea. I have witnessed it more particularly in cases where the rapid type has prevailed, and when the surface of the body has resumed its heat during collapse; for some remarkable exceptions to the common run of symptoms take place in the state of collapse. After a while the heat increases to an astonishing degree, so much so as to present a peculiar burning sensation to the touch; the perspiration becomes also heated, but with re-

spect to quantity remains the same; and this heat never diminishes until after death. This anomalous heat I have always observed to occur in cases where an extraordinary quantity of stimulus had been exhibited.

There was also, in many of the cases, after death, an extraordinary motion and confusion amongst the muscles in different parts of the body, and an irregular contraction going on to an astonishing extent. This may be seen in many parts of the body in a given number of cases; but, in the majority, happens most in the muscles of the thigh and abdomen. I have, indeed, seen the lower jaw separate itself completely from the upper, as though the patient opened his mouth wide to get breath, at a considerable period after death. The contraction of the muscles of the abdomen is often so perfect as to imitate the breathing of the patient, and to excite doubts whether he is not, in a most remarkable manner, reviving.

Treatment.

As a great deal of the practice instituted in Canada was unsuccessful, the bare mention of those means (which, indeed, were principally selected from the proposals of practitioners in other countries) will be sufficient, previous to reciting that which did appear, in some cases, to produce or facilitate recovery. Hot or warm water baths invariably appeared to injure the patients by exhaustion. Tinctures of a stimulating and heating kind never produced any decided benefit. Saline medicines, champaign, and cold water, seemed worse than useless, by very much augmenting the secretion of the alimentary canal, and so exhausting the powers of life. Nitric acid never acted well topically. Large opiates were not considered good in themselves, although opiates were used beneficially to a certain extent,—of which more anon. Acetate of lead and hydrocyanic acid did not produce much evident effect any way; and injections into the veins, although stated to be attended with successful results in other places, were followed either by apoplexy or delirium in all the cases in which I saw it tried: perhaps, however, there might have existed some untoward circumstances to account for this, either in the time, quantity, or method of administration; and the number of cases operated on were not numerous. I will, therefore, now briefly state that practice which, with a little modification, was most successfully pursued.

When a patient was attacked with premonitory symptoms, we administered an emetic of ipecacuanha, conjoined with a little carbonate of soda, a pediluvium, and an immediate immersion of the body between warm blankets: after a while, ten grains of calomel, with one of opium, were given: and the same medicines were repeated several times, in the proportions of two or three grains of calomel, with an eighth of a grain of opium, at intervals of three hours. One or two moderate doses of castor oil, to render the bowels sufficiently open after the secretions were healthy, generally effected the cure.

But in the first stage of the real disease we have to use both caution and expedition, whilst we employ the most energetic treatment which the patient is able to bear. Bleeding, in moderate quantity, was a very successful mode of practice, and was effected with all the speed possible; this process often relieved the urgent symptoms immediately. With respect to what kind of artificial heat it was best to employ at this stage of the disease, it became necessary to consider that prostration of strength was fast approaching; that the disease was then peculiarly violent, and of hasty progress; that the slightest exertion exhausted the remaining strength of the patient, which is the only foundation we have for our efforts; together with the general opinion of the medical men there, that, from what they had witnessed, the exhausting influence of warm water was of itself sufficient to destroy the remaining vitality of the patient. All these things, therefore, combined, made the application of *dry heat* I may say universal. Tin vessels of different sizes and shapes, made to fit the several parts of the patient's body, were filled with hot water, and applied as universally as possible; hot bran, or wheat, or barley, in bags of flannel, or hot sand in the same, together with a sufficient covering of flannel and blankets, were the means resorted to for applying it. As soon as possible, likewise, an emetic, consisting of forty or sixty grains of ipecacuanha, and half a drachm of carbonate of soda, combined, was administered, and rather a liberal quantity of warm water given, to excite vomiting: the result obtained

here by a pretty smart vomiting was generally a good one. After the commotion of the stomach had for a short time subsided, twenty (and sometimes thirty) grains of calomel, with half a grain or a grain of opium, was given; care, however, being taken during the whole treatment not to administer too much opium; the principal object in its exhibition being to make the calomel rest quietly on the stomach. If this first dose of calomel was rejected, it was repeated after a short interval, when it generally remained, unless the disease was inclined towards the next and more dangerous stage. Afterwards three grains of calomel, with an eighth of opium, were given every two or three hours, care being taken at the same time to keep up the heat of the body. The patient was not allowed much drink, a very small quantity of gruel or tea only. In this stage the cramps are often considerable, but are often relieved by heat; or if that does not succeed, by rubbing. I have, however, seen, even at this period, cramps so severe, as to leave behind them large extravasated blotches when the patient was recovering, as high up as the middle of the femur. The mercury was now carried on sufficiently far to produce ptyalism before the patient was considered safe. The subsequent treatment was commonly effected by castor oil, and a cautious introduction of diet. Port wine in small quantities, when sufficient recovery had taken place and sufficient time elapsed, was decidedly beneficial.

If the case had advanced to the second stage before the patient was seen (which not unfrequently occurred), the utmost care and expedition were required, in order to sustain the heat of the body, and also as much as possible to increase it; which was attempted by the means above mentioned. It was now a question of great importance to decide, and to decide expeditiously, whether or not venesection might be resorted to. For the most part, if the constitution of the person suffering seemed to be unimpaired by dissipation or infirmity, and the pulse retained a moderate volume, the result of a small abstraction of blood was beneficial; but if the constitution had suffered much from debauch, or sickness, or variations of climate, or if it was naturally weak, especially in advanced life, then, on the contrary, bleeding was invariably followed by quick collapse. An emetic was, however, given, but not so large a one as that in the former stage; for if great care was not taken to husband the strength of our patient, he sank almost without passing through the subsequent stage. But if the patient had been seen from the first, and, notwithstanding our efforts, the case had thus far advanced, then a domestic enema, with plenty of salt, was administered; and this usually contained an ounce of castor oil, and one or two ounces of spirit of turpentine; but sometimes, instead of these last, if the patient was of a very robust habit, from thirty to sixty grains of emetic tartar; and these injections were sometimes repeated with evident advantage. A rag dipped in spirits of turpentine, or a mustard plaister, was at the same time placed upon the region of the stomach, and retained there as long as it could be borne. The best stimulant wherewith to rub the external surface of the body, and to allay the cramps and spasms, was spirit of turpentine: but for this labour a considerable number of persons were required to be in attendance; and it was necessary, for the benefit of the patient, that they should be indefatigable. If possible calomel and opium were continued, in the proportion of a grain or two of the former, with an eighth of a grain of the latter, every quarter of an hour: occasionally twenty grains of carbonate of soda; a tea-spoonful or two of brandy whenever the pulse became very small; and to prevent large potations, a piece of ice now and then put into the mouth, which the patient always sucked with the utmost greediness. I have seen patients so employed almost in the act of dying.

But too often all these efforts are unavailing, and, with the utmost rapidity, this terrible disease advances onwards to the last stage. Little is then to be expected from our remedies; but yet every moment must be made the most of, and we must be as unremitting as possible in our exertions. And here I would say, that it requires no common share of courage to be enabled to act at all. The dreadful state in which the whole apartment is at this time excites so much horror, as well nigh to overcome the strongest mind. Emetics at

this crisis (supposing no previous treatment) for the most part were instrumental in destroying life, by excitement. Clysters were used, more as experiments than any thing else, composed of gruel mixed with two or three drachms of tincture of opium, and one, two, or three ounces of brandy, or from four to six of port wine. Some question was raised whether, at this period of the disorder, the clyster should be large or small in quantity; both were tried, and I should say that a decided preference was given to small ones; for although I am not prepared to say that the difference ever proved of sufficient importance to attribute recovery or death to it, yet, as in all the preceding stages, it had been considered best to allow but little fluid to be introduced into the alimentary canal, and as it never appeared that a large clyster produced benefit from its mere bulk, but perhaps served in part to exhaust the remaining powers of life, by causing so much to repass the anus (for these injections, however anodyne they were made, were speedily returned), operated in persuading us that the less the clysters the better the effect.

Very large doses of morphia were now given; ice was still used sparingly; and wine or brandy (which last is best) in exceedingly liberal doses, every three or five minutes. A drachm of rectified ether, with twenty grains of camphor, every five or ten minutes. These doses may appear large, but it is merely trifling with a patient to make them smaller at this most critical juncture; added to which, the system does not in any way appear to be acted upon by doses of an ordinary kind. Carbonate of ammonia, and, indeed, all the stimulants, were here resorted to; the indication being to prevent the collapse, which most imminently threatens every moment.

It is necessary that blistering should not be overlooked: if the symptoms were very urgent in the second stage, blistering became necessary, in order to have the advantage of time; but if we did not find ourselves called upon to apply this remedy so early, it always became necessary when the last stage had set in; and I venture to assert, that the more the patient's body was covered by blisters, the more chance he had of recovering. Blistering the whole spine, from the head to the coccyx; blistering the regions of the stomach and abdomen; applying blisters round the arms, legs, and even over the whole scalp, is what in some cases we successfully did. In one particular case, in 1832, this treatment was fully acted up to, in a second attack of cholera, when the patient was perfectly collapsed, saving a little warmth on the body, for nearly fifty hours; after which he perfectly recovered, and was, even very lately, officiating as a surgeryman in the Garrison Dispensary of Quebec. In a few other cases, the natural constitution seemed to assist in passing through this deadly trial, and to rally,—burnt brandy being principally administered by the mouth. In the rapid type the indication was altogether to keep up the heat of the body, and get stimulants to act in such a way as to produce revival. I need not, however, say, that our efforts were generally in vain.

The subsequent fever which occurred in those cases where recovery was not complete, possessed much of the typhoid type, and sometimes ran a most tedious course, yet subsiding at last. There appeared always to be gastro-enteritis; but I suppose rather as a consequence than a cause of the original disease. It is needless in this place to repeat the variable treatment which was resorted to; I shall only observe, that when these patients were convalescent, bottled porter seemed frequently to restore them to their former vigour sooner than any thing else.

Morbid Anatomy.

The principal post-mortem appearances which I have observed are the following:—Congestion of the vessels of the brain; ecchymoses on the pia mater at its base, particularly under the medulla oblongata; an absence of water in the ventricles; patches of ecchymoses immediately upon the trunk of the par vagum (these last above, but near the division of the carotid and subclavian); patches of small size upon the artery itself. Lungs extremely engorged; pericardium nearly empty. Heart covered with remarkably distinct, and somewhat large ecchymoses; serum and black blood coagulated in the auricles; extreme injection of the outer coat of the aorta; inner coat of the aorta having a

livid shade. Omentum considerably engorged. Stomach partly distended with a whitish semi-mucous liquor; internal surface flocculent. Duodenum two-thirds filled with biliary secretion, rather dark and inspissated; small intestines generally containing a bilious secretion for a short distance, sometimes rather fæcal; otherwise nearly empty; internal membrane flocculent; small intestines, particularly towards their termination, injected with bright-coloured blood. Colon partially filled with a whitish semi-transparent fluid, something like the dejections. Bladder empty, exceedingly collapsed, and drawn to the bottom of the pelvis. Kidneys gorged; liver gorged in its nervous system, and its substance altered in colour to an ash, or livid yellow. Gall-bladder nearly full, and its contents dark.

I have thus hastily drawn up this fragment, amidst a multiplicity of duties and a great variety of occupation. My desire is, that if it contains any thing worth knowing it may be made known; and for this reason I have not pretended to argue any points connected with the mysterious pathology of this fatal epidemic, however interesting in themselves, or showy in their announcement; but what I have written I have written with confidence, as of matters which I have myself seen and handled; and, moreover, have, in some measure, sadly experienced in my own person.

MUSCULAR IRRITABILITY.

To the Editor of the Medical Gazette.

SIR,

I FIND by Dr. Alison's reply of the 14th ult., that the objection of Dr. Allen Thomson was not exactly that which suggested itself to my mind; for I never doubted the accuracy of Dr. Reid's statement. I suspected the experiment to be an imperfect one, from which, consequently, no sound conclusion of any kind could be drawn: this suspicion is now confirmed by Dr. Alison himself, when he says that the irritability of the muscles was only *diminished.* There is, therefore, no reason to doubt Dr. Reid's accuracy, since, like those experiments of Mr. Hunter on the question of the impossibility of absorption by veins, it is clear that it may be perfectly true, and equally evident that it does not bear at all on the real point where the proof was necessary. Dr. Alison ought to bear in mind, that no evidence can be admitted which falls short of proving the existence of muscular action after the *complete destruction*, or *exhaustion*, of the nervous influence. If he is able to bring forward positive proof to this extent, I shall be ready to acknowledge that I have been in error; but if he cannot do this, which he will recollect has never yet been done, I should hope that he on his part will not hesitate to make a similar admission.

I may observe, in conclusion, that the grand point wherein the generality of physiologists have erred, is in conceiving that the nervous influence is destroyed by the division of a nerve, or of the spinal marrow, as when the head of an animal is cut off; whereas the nervous influence is, in fact, no more destroyed by such an injury, than the blood is destroyed in an artery when a ligature is thrown around it.

I remain, sir,
Your most obedient servant,
J. W. EARLE.

64, Welbeck-Street,
Oct. 5, 1835.

OBSERVATIONS

ON THE

CHANGES PRODUCED IN THE BLOOD IN THE COURSE OF ITS CIRCULATION:

WITH EXPERIMENTS.

Read to the Royal Medical Society of Edinburgh in 1823.*

WITH ADDITIONS AND REMARKS ON DISCOVERIES AND OPINIONS SUBSEQUENTLY PUBLISHED.

BY CHAS. J. B. WILLIAMS, M.D. F.R.S. &c.

[Concluded from preceding vol. page 876.]

On the Origin of Animal Heat—continued.

IF we compare with the general results of the experiments which have been

* This essay formed the subject of a thesis published in Latin in 1824; and in 1826 an abstract of it was published in the Transactions of the Medico-Chirurgical Society of Edinburgh. The additions are enclosed in brackets.

described or noticed in the preceding observations, the views which I have advanced respecting the changes of the blood and animal heat, we shall find them to be in perfect consistency with the phenomena, and explanatory of them.

It is not impossible to reconcile these views even with the extreme results of Mr. Brodie's experiments. According to our theory, the carbonic acid exhaled by respiration is what has previously existed ready formed in the blood. The usual quantity of this gas might therefore be *emitted* for the first half hour, without a sufficient quantity being actually *formed* to preserve the heat of the body. That little carbonic acid is formed where the nervous influence has been destroyed, appears further probable, from the fact observed by Le Gallois, that the blood does not in this case assume the proper venous hue; and this is, most likely, because the secretions, which we have shown to supply carbon for this purpose, are suppressed. This suppression also removes the other process which we have supposed to be a direct source of heat—namely, the formation of the principles of the secretions.

If it is possible to explain these extreme results, there can be no difficulty in accounting for the phenomena observed by other physiologists, and by myself, in which for a short time animal heat *was* kept up by artificial respiration. Hence we must either ascribe to the functions of respiration and circulation the power of generating heat (although to small extent, unless supported by other functions), or, with those who attribute to the nervous energy a power almost omnipotent—assume that the heat generated after the removal of the brain is produced by the nervous organs still remaining in the body. This latter alternative is so entirely destitute of support, that it is unnecessary to discuss it. I will, however, remark of the only author who, to my knowledge, has advocated it, that he had a particular hypothesis involved in it. I allude to Dr. Wilson Philip, who considers animal heat to be a *secretion*, a *tertium quid*, resulting from the operation of the nervous energy, or electric fluid (for he holds them to be the same), on arterial blood*. If, by this expression, he implies that the evolution of heat is the only consequence of the supposed action, I affirm that his proposition is not in accordance with the known properties of heat, nor with the generally received opinions of its nature; but if he admits that the supposed action is attended with other changes, besides the mere evolution of heat, his term *secretion* is logically inaccurate; for the heat must be the result of these other changes (whether in composition or in condition) of the principles of the blood, and not the direct effect of the supposed nervous power on this fluid. That such was the case in Dr. W. Philip's experiments with galvanism and arterial blood, a perusal of his account of them will sufficiently prove; for the rise in temperature which took place on passing the electric current through florid blood was attended with a blackening and obvious change in the chemical condition of this fluid.

[Since the foregoing remarks were written, the opinions of philosophers respecting heat have undergone some change, the notion having gained ground that it is the undulation of an elastic medium rather than a distinct matter. This will but little affect our subject; for we have less to do with the nature of heat than with the laws of its development. We find heat continually evolved in the animal body; and if we can point out according to what physical or chemical law it is there produced, we explain its cause as far as is necessary in the science of physiology. Any notion which falls short of this is not an explanation. Such appears to me to be the opinion of Dr. Wilson Philip, above quoted. To call heat a secretion, in spite of its want of parallelism with any other secretion, is to substitute an hypothetical, and probably erroneous, term for an explanation. With more plausibility animal heat might be referred to the calorific power of a current of electricity passing through an insufficient conductor. When a large quantity of electricity is sent through very fine metallic wires, it will heat them even to incandescence and fusion. The heat is here truly a *tertium quid* (a *secretion*, if you will), resulting directly from the action of electricity on the metal; there being no chemical or physical change to account for it. But if we admit (as I think we must) that there are electric currents continually present in the animal frame, there is no trace of the condi-

* Experimental Inquiry, &c.

tions under which they can produce heat, as in the case just described. There is no where in the body a sign of so strong a current, or of insufficient conductors. Besides, nearly all the solids and fluids of the body are electrolytes, and chemical changes would accompany the passage of electricity through them, as in the case of Dr. Philip's experiment, which destroys the analogy with the case of conduction by a metal. If, then, electricity be a direct cause of animal heat, it must be through some property not at present known; and to assume gratuitously the existence of such a property, is contrary to all rules of philosophy.

The hypothesis that electricity is the direct cause of animal heat being unsupported by analogy or experiment, we have again to inquire whether the position which I have advanced, that the chemical changes continually going on in the system will explain it, is still tenable. This view requires further consideration than I had given it in the preceding essay, and it may be conveniently examined under the following propositions:—

1. Certain kinds of chemical change are attended with an evolution of heat.

2. Such kinds of change do take place in the living body.

3. Relations are observed to subsist between these changes and the production of heat in the living body.

1. It is well known that when bodies pass from a gaseous to a liquid state, or from a liquid to a solid state, they give out heat. The same phenomenon accompanies any change in a body from a rarer to a denser condition. The most numerous and remarkable sources of heat are, however, the changes accompanying chemical action; and at the head of these stands the familiar one of combustion.

The phenomena of combustion depend on a certain intensity and rapidity of chemical action, which, when moderate and slow, does not give out heat sufficient to be luminous. Thus a mixture of hydrogen and oxygen in the proportions to form water, when heated sufficiently, unite instantaneously, and by the heat, light, and explosion, exhibit the intensity of their mutual action; but if heated to a lower degree, or if much diluted with some neutral gas, and exposed to spongy platinum, they then unite slowly and silently, still giving out heat, but not with the rapidity and quantity necessary to constitute combustion and explosion. This example, although elementary, illustrates generally the principles of calorific union. We are apt to associate the generation of heat especially with combustion, forgetting that this phenomenon exhibits only the higher degrees of what occurs also extensively when similar chemical changes take place more slowly, or when circumstances prevent the accumulation of heat. Water has this latter effect in a signal degree; and as this property is materially concerned in the calorific processes which are to come under our notice, I will illustrate it by a simple example. We know how sudden and vivid is the combustion of dry gunpowder. When the mutual action of its component parts is developed, nothing interferes with the extrication of heat, which is accordingly intense and instantaneous; but if the powder be moistened, the evaporation of the water impedes the heating process, and the combustion proceeds through the mass more slowly, and less vividly. Again, expose the chief components of gunpowder to each other's action in a watery medium, by warming sulphur and charcoal in nitric acid; the chemical changes are much the same as in the former case, and heat is evolved; but the liquid impedes its extrication and the rapidity of the action, which therefore go on in a lower degree, and for a longer time. This instance of gunpowder is given, because its constituents and their mutual action are well known; but it would be easy to shew that many other chemical actions, which, at their acmé, exhibit the phenomena of combustion, are, in their lower degrees, and when retarded by the presence of a cooling mass of water, still attended with the gradual extrication of minor degrees of heat.

In a somewhat similar light may be viewed the processes of fermentation and putrefaction, which develope low degrees of heat; and their chemical nature, although different from that of common combustion, may be proved to pass into it by successive gradations. It is thus, as I have elsewhere shown, that many cases of spontaneous combustion originate. Take, for example, the

spontaneous combustion of damp, or newly-made hay. This arises from a fermentation produced by the presence of moisture; but the heat thereby generated gradually dissipates the moisture, and developes the other ultimate affinities between the vegetable matter and the air. Hence the hay emits at first a fragrant steam, then an empyreumatic smoke, whilst its interior becomes charred by the increasing heat, which, under favourable circumstances, at last breaks out into open flame.

It would lead us beyond the immediate purport of this essay to pursue this part of the subject further here: the examples adduced will suffice to show how generally heat, in various degrees, accompanies certain chemical actions. *What are these actions which produce heat?* is a question still requiring a brief notice. It may be answered, *those kinds which tend to the formation of simple and permanent products.* The most efficient cause of heat by chemical change is the union of two contrary elements, with no opposing affinities to restrain their combination. Such is the union of oxygen with hydrogen, with carbon, &c. The next in calorific effect may be the open combustion of various animal and vegetable matters: the simplest products result; but the development of heat is somewhat impaired by the pre-existing slight affinities, and the presence of some oxygen, already in the combustibles. A lower degree of heat, but yet luminous, is produced in the low combustion which I have shown to affect most combustible bodies, both simple and compound, at temperatures considerably below red heat*. The products of this combustion in vegetable and animal matters are, according to the kind, chiefly water, empyreumatic acetic acid, oxalic acid, carbonic acid, and ammonia; all more simple in ultimate composition than the combustible. Lastly, the lowest cases of calorific change are those of fermentation and putrefaction. In one sugar is converted into alcohol and carbonic acid, or alcohol into acetic acid; in the other, animal and vegetable compounds are resolved into ammonia, carbonic and hydrocyanic acids, carburetted hydrogen, and the like: in both these cases the change being from the more complex organic principles to combinations simpler, and more resembling the permanent products of combustion. We may therefore reduce all the above instances to this general law—*the evolution of heat during chemical action is, cæteris paribus, in proportion to the change from isolation, or weak combination, to firm and simple union.*

2. Our next position to establish, is, that such chemical changes as have been just shown to evolve heat, do take place in the living body. We know of no processes in which the condensation of gases, or solidification of liquids, can become a source of animal heat. It is true that, in nutrition or reparation, the solids are formed of the liquid blood; but this is balanced by the opposite process of decay, in which the solid structures are again removed in a fluid state by the various absorbent vessels; and by the operation of chylification, in which a liquid is extracted from a more or less solid mass of aliment.

But the several chemical changes in the blood which we have been considering in the preceding pages, I apprehend we shall find included in the definition above given of the production of heat by chemical action. That the union of carbon and oxygen must prove in the body as elsewhere a source of some heat, is too obvious to need further argument. I shall here only consider the changes effected in the formation of the secretions. Here, from the highly perfect animal principles, albumen and fibrine, which originate only in living bodies, are susceptible of organization, and become the medium of some of the most remarkable properties of life,—we find produced, urea, uric acid, ammonia, picromel, resin of bile, lactic acid, and the like; matters not only totally insusceptible of organization, but obviously approaching in nature to inorganic substances, and capable of being formed by the decomposition of other organic matter, and in some instances even by the synthesis of inorganic compounds. Thus urea consists of precisely the same elements as the hydrated cyanate of ammonia; it may be formed artificially by the action of ammonia on cyanogen; and as it exists in urine, a boiling heat is sufficient to resolve it into the still simpler carbonate of ammonia.

* Transactions of the British Association for the Advancement of Science: vol. iii., Chemical Section.

The uric and lactic acids also approach to ultimate compounds; the former differing but little from some of the combinations of cyanogen, and the latter being the product of fermentation of milk and other animal fluids. Of picromel and the resin of bile we can speak with less certainty; but their ultimate composition, resembling oils, varieties of hydro-carbon, bespeaks the simplicity of their nature.

As we thus find the principle of calorific change fulfilled in the formation of the excretions of the animal body, so we may have experimental illustrations of it in the further history of the excreted matter. Thus in the septic properties and progressive decomposition of the urine and dung of animals we see a continuance of the simplifying process which had begun in the body; whilst the attendant heat, so familiar in the steaming dunghill, and usefully applied in hot-beds for forcing plants, exhibits the constancy of the phenomenon, which in its earlier periods had assisted to sustain the temperature of the living animal.

3. The last position to be examined, is, that relations are actually observed to subsist between the chemical changes going on in the body, and the animal temperature.

I need not dwell on the general relation observed between the heat and the perfection of the respiratory process in healthy animals. This has been sufficiently pointed out by the various writers on the subject, from the time of Dr. Black and Lavoisier. The experiments of Edwards have added a new proof, in the fact that young animals gain the power of preserving their own temperature in proportion as respiration becomes necessary to them. Animals born blind, or without covering, partake somewhat of the fœtal state, and will live for a short time without air; in this condition they have very little power of generating heat, and depend in great measure on the warmth of the mother: but as the respiration and connected functions become more perfect and indispensable, they gain the power of sustaining their own temperature. The exceptions to this law of relation in the experiments of Sir B. Brodie, and of those who have followed him, do not disprove it; they only shew that a certain integrity of the nervous function as well as of the respiratory is necessary for the preservation of animal heat. But, as it has been already observed in this essay, these experiments afford a direct illustration of the relation which we seek to establish between certain chemical changes and animal heat. A quotation already given from the accurate Chossat comprehends the result of his and all other experiments on this point. "*All the lesions of the nervous system which diminish the production of animal heat, act in a similar way on the secretions.*" Here, then, we find the exception proving the rule. A certain integrity of the nervous function is necessary to maintain animal heat, because it is necessary to the continuance of those chemical processes on which animal heat depends. It is directly necessary to the formation of the secretions, (one cause of heat) and as these supply carbon to maintain the production of the carbonic acid of respiration, (the other cause) the nervous energy is also necessary to the continued perfection of this function. Some production, as well as exhalation, of carbonic acid, may take place after the destruction of the nervous influence; and my own and other experiments shew that some heat is at the same time evolved. But this portion of calorific power is insufficient to preserve the heat of the blood: hence, besides the absence of the agency which forms the secretions, the increasing depression of temperature diminishes even the changes which the oxygen absorbed can *chemically* effect; the cooling is therefore progressively rapid, and when it has reached a certain degree, artificial respiration accelerates instead of retarding it.

I have before had occasion to cite from Dr. Hodgkin's notes to Edwards, some experiments of Sir A. Cooper which illustrate the effect of intense cold in arresting the changes of the blood in a sound animal, that in the veins retaining the arterial hue. It at once destroys that nervous influence, and impairs those chemical affinities, which jointly work the calorific changes. Such a moderate degree of cold as the vital powers can react upon has an opposite effect; more counteracting heat is generated, the blood becomes darker, and more carbonic acid is given out from the lungs;*

* Crawford, Lavoisier, &c.

and it is this exhibition of a property peculiarly vital, adapting the laboratory of the body to a variety of states, that distinguishes living from dead chemistry, and makes the very laws of decomposition subserve to maintain the heat and health of the body. We are familiar with the effect of external cold in increasing the secretion of the kidneys, and are used to ascribe it to the mechanical change of the circulation of blood thrown inwardly from the constricted surface; but nature's beneficial purposes are not limited to this, for in this inward determination of blood we also see a beautiful provision for the maintenance of animal temperature by an increase of those changes in which the internal viscera are materially concerned.

The relation of the heat and respiration of very young animals has already been noticed; but we have to add the correspondent relation of the state of the secretions. In the fœtus the secretions are scanty, and devoid of distinctive character, the power of producing heat being at the lowest; but as soon as the animal has breathed, the vital energies are excited, the chemical changes are promoted, the glands yield their peculiar secretions, and the power of maintaining heat is proportionately acquired.

These last considerations deter me from reckoning *nutrition* among the chief calorific processes of the animal body. The only way in which I see that it can contribute to produce heat is in the trifling extent to which it may (as before noticed) supply carbon for the respiratory function. But the opposite process, *decay*, which is supposed by physiologists to be continually affecting the tissues of the body, is essentially one of those simplifying changes which are always attended with an evolution of heat, and we thus find that this process, which has hitherto been deemed a result of defective composition, whether we view it as a distinct operation or as a part of the function of excretion, answers the useful and important purpose of contributing to sustain the heat of the body.

The necessity of a controling power over all the chemical changes which thus sustain animal heat is as obvious as is the need of a similar influence to predominate over the various physical properties of the animal machine; and if in the agent by which that control is exercised we recognise some characters which approximate it to electricity, we step but little higher in the mysteries of vitality. What directs this agent, and what are its relations to the physical and chemical laws which act upon it, and which it so powerfully and beneficially controls, are matters which according to our present knowledge are entirely beyond our comprehension. We have been studying the chemical changes as they do occur under this unknown influence, and find in them a sufficient cause of the heat of the animal frame. This inquiry, far from degrading our view of the animal economy into a mere application of chemical or mechanical laws, exalts and enlarges it, in the further proofs which it has afforded, that these laws, which in dead matter tend to decompose and to destroy, are made under the influence of vitality to warm, sustain, and purify the living body. In the variations of disease, which are too numerous to admit of present notice, we may find proofs of insubordination in the chemical agencies which sometimes seem even to predominate for a while; and in the balance of these against the opposite ones of vital reaction, are comprehended many of the phenomena of morbid action. The physical condition of temperature is, however, still amenable to the laws of its production; and in the highly charged excretions and increased carbonic acid expired in inflammatory fevers, we see the causes of augmented heat; whilst the lower temperature in typhoid, cachectic, and dropsical states, is accompanied by a diminished excretion from all the important organs.* Other causes may doubtless be assigned for these variations of functions and phenomena; nor do I deny their reality: and in adducing these new relations of acknowledged facts, I do but shew further instances of the admirable economy of nature, by which the chain of causation, although consisting of many links, is at once simple, comprehensive, and harmoniously adapted to a variety of ends.

COLLEGE OF PHYSICIANS.

DR. PHILIP IN REPLY TO DR. JOHNSON.

To the Editor of the Medical Gazette.

SIR,

IT has pleased the Editor of the Medico-Chirurgical Review, in the number just published, to make, under the title of a review of my Gulstonian Lectures, an attack on me in consequence of my having been elected a fellow of the College of Physicians.

The degree of credit due to his observations will appear when I state that I attended but one meeting of the College between that at which I obtained my license, about fifteen years ago, and that at which I was received as a fellow; and I never either directly or indirectly intimated to the President or any other Fellow any wish to obtain a fellowship, or took any step of any kind whatever with such a view: so far from it, indeed, that, although gratified by the flattering offer made to me, there was more than one reason which for several days caused me to hesitate whether I should avail myself of it: a fact well known to one of the most respectable members of our profession, whom I consulted on the occasion, and to whom I stated the reasons here referred to.

Such being the case, to what am I to ascribe a *tirade* written in absolute ignorance of the facts, and which sets all good taste and delicacy at defiance? Is it possible that it could have originated in any feelings which a man who has the least regard for his respectability would venture to acknowledge?

The truth is, that with regard to the by-laws of the College, which excluded from the fellowship, except under peculiar circumstances, the graduates of other Universities than those of Oxford and Cambridge, but which have since been repealed, having never experienced any inconvenience from an exclusion which implied nothing personal respecting the individual, I had never particularly directed my attention to the subject; and at the time I declined signing the petition of the Licentiates, I certainly had no reason to suppose that a fellowship would have been offered to me. My only reasons for refusing my signature were that just mentioned, my not having sufficiently attended to the subject to see all its bearings, and my dislike to come forward on such occasions.

Why is Dr. James Johnson so much offended by what I say of the medical scribblers of the day? It cannot apply to all medical reviewers, many of whom are among the best informed of our profession.

The review which follows, both with respect to the knowledge and feeling it displays, is such as might be expected after such a preface.

In all my late publications—a Treatise on the Preservation of Health, that on the Effects of Minute Doses of Mercury in gradually restoring the Vital Functions, the republication from the Philosophical Transactions under the title of A Treatise on the Nature of Sleep and Death, my Gulstonian Lectures on the more obscure affections of the brain, as well as my Treatise on Indigestion—I have had the same object in view; the application of the long series of experiments which have for the greater part of life occupied the time I could spare from the more active duties of the profession, to improve our knowledge of the nature and treatment of diseases; and it is gratifying to me that I am entitled to state, from the testimony of many members of our profession, that my objects have not been altogether unattained. But those who either will not be at the trouble, or are incapable, of entering with any accuracy into such inquiries, only see in the foregoing publications a reference to the same train of experiments, ; and here, as on other similar occasions, the most ignorant are the most confident. They neither see the difficulties, nor can judge of the means by which an attempt is made to remove them. What I have done will remain as far as it is consistent with truth. I wish nothing more.

I am, sir,
Your obedient servant,
A. P. W. PHILIP.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Practical Observations on the Nature and Treatment of Nervous Diseases: with Remarks on the Efficacy of

Strychnine in the more obstinate Cases. By George Russell Mart, Member of the Royal College of Surgeons in London, &c.

Mr. Mart's preface sets forth—

"The following pages contain what may be considered new information respecting the treatment of such chronic nervous diseases as are too often pronounced incurable. The virtues of *strychnine*—the remedy chiefly used—are imperfectly known, and it has not received that degree of attention which its merits demand. Secondly, to prove that various complaints, if they do not admit of relief at one period, are capable of alleviation at another;—and to impress upon patients who have long been afflicted with these distressing maladies, the necessity of persevering in the method recommended in these pages; more especially, when it will be found that in the majority of cases which appeared hopeless, the method has been efficacious."

A word on this. We have in vain sought in the book for the "new matter," or information; the matter is very familiar—an old friend with a new face. Moreover, we deny that the "virtues of strychnine" are imperfectly known; nor are we strangers to its vices, any more than the dogs who have suffered in the cause. Assuredly, if Launce's dog were to look out of his grave, there would be much wringing of hands for those of his species who have become acquainted with the "virtues of strychnine."

The utter hopelessness of the public ever being able to appreciate or apply medical knowledge, diagnostically or curatively, must always expose the practitioner who tenders it, to the suspicion of having an *aim* less direct than the *sole* benefit of the laity. That this work is addressed rather to the public than the profession, the above quotation is an unfortunate proof. Apart from every other consideration, such as the danger of entrusting patients with so active and expeditious a poison as strychnia—the moral effect of attempting, or professing, to popularize physic, is exceedingly pernicious; for it brings into ill odour and contempt the whole body for the sins of the few, whose bad taste or cupidity have incited them to the medical misdemeanor of mantling empiricism by *book* advertisements,—a practice no less degrading and dishonest than Goss's or Eady's, and, unhappily, becoming nearly as frequent. To complete the misfortune, when the meanness meets with castigation and exposure, the cry of "jealousy" is raised by the populace, and joined in by the delinquent, who of course encourages the vulgar belief that the legitimate is envious of the wisdom and good fortune of the quack: in truth, the "public" is an exceeding fool, somewhat ungrateful withal, and far more likely to rend the medical watchman than the charlatan thief.

Mr. Mart adopts a notion with respect to nervous affections, strongly savouring of one of the rejected articles in the creed of humoral pathology, *viz.* that a "morbid state of the blood" must stand accountant for the sin of their production.

Few doubt the fact of a changed condition of the blood being competent to cause diseases of varying kinds and severity; but such affections are for the most part *constitutional*, not *local*, (if we except some cutaneous affections.) Few maladies are more decidedly *local* than the "nervous affections," for which strychnine has been so abundantly employed, and, (if we take the evidence of the impartial and disinterested,) with any thing but encouraging success.

Spasmodic, painful, and paralytic affections, depending upon lesions of the cerebral or spinal organs, are necessarily beyond the possibility of *cure*. Time may abate, remedies alleviate, but cure never. The same affections depending upon those intangible causes, called functional derangements, are often medicable, chiefly when treated on *general* principles, and sometimes by means which operate *sui generis*, as galvanism, or electricity, and magnetism, perhaps (?) Nevertheless, failure is sufficiently frequent to forbid the indulgence of a reasonable hope that "the more obstinate cases of nervous affections" may be tractable to any known remedies, not even excepting the virtues of strychnine. It were useless to deny that good results have been *apparent* from its use; but have these been the *effects* of the remedy? No cases have ever convinced us; yet writers of such books as Mr. Mart's would have us adopt the advice of Friar Michael,—to take the implication for absolute; and, without looking into the fact *whether*, seek only the reason *why?* And by consequence they are never deficient in hypotheses, "physical-natural, physical-historical, or natural-superinductive." Our belief is, that a willing self-delusion is practised when the expectation is indulged, and

talked of as *just not* inconsistent with possibility; that "specifics" may some day be found to add to the surprisingly long catalogue "bark, brimstone, and mercury:" and then we are favoured with the shrewd inquiry—Who would have thought sixty years since that so many apparent impossibilities would have been surmounted by modern science and ingenuity? Then follows a cloud of examples in point, such as steam-boats, gas-lights, and the musical glasses! Reasoners like these are ignorant of an impossibility *in limine*, or of an antagonist and incremental difficulty in many of their fine speculations; such are the persons who would hope to *double* the speed by merely *doubling* the power; they are of that school of philosophy, whose founder—we are told by Lear's fool—out of sheer kindness to his horse, buttered his hay!

To return to the author. His pathology is vague and indefinite; and his generalization appears to be of the kind that founds a general conclusion upon a single fact. He is unmindful of the powerful aid derived from the auxiliaries which were employed conjunctively with the "virtues of strychnine;" or, if cognizant, somewhat ungratefully omits to acknowledge the obligation. Sir Abel Handy says—none of his specifics being at hand,—"Well, perhaps the fire may go out of itself." Certain is it that many disorders realise the baronet's expectation, *quoad* the fire: they exhaust themselves; nervous and hysterical affections one of them; yet magnets, metallic tractors, with other equally questionable agents, appropriate the merit. There is not a class of disorders more numerous, more embarrassing, than that whose characteristics are referable to some permanently or periodically deranged condition of the nervous system: the fact of their being too often regarded as the results of organic disease, and subjecting the unhappy patient to active treatment, adds to their consequence; but we contend that they will never be better understood, nor their treatment improved upon, by regarding them as depending upon a general or common cause, which is certainly inferred by the general recommendation of a common remedy.

Disquisitiones de Animalium vertebris carentium in Ovo formatione: De Generatione Insectorum in Ovo. Auctore Maur. Heroldio, Jenensi, M.D. &c. Frankf. am Main, 1835. —Schloss.

We learn from the prefatory notice attached to this splendid work, that the author, Professor Herold, of Marpurg, has spent eighteen years in its preparation. We are not surprised at such an announcement when we see what has been done: the plates in the present fasciculus representing the development of the eggs of insects, as observed with the microscope, indicate the most unwearied diligence and perseverance. As a work of art we never saw any thing to equal the representation of the *Bombyx quercus*, just issued from the egg, given magnified to about 600 diameters: of the faithfulness of the figure we entertain no doubt, seeing the wonderful minuteness with which all the details are executed. Some interesting remarks on the comparative value of simple and compound microscopes are prefixed to the explanations of the plates: and the author candidly asserts that diligence in observing is a better auxiliary than any optical contrivance even of the highest powers.

There are to be four fasciculi altogether to complete the work. The present, which is the first, contains both outline and finished coloured copperplate views, 1, of miscellaneous ova and their elements; 2, the ovum of the *Bombyx quercus* at different intervals after birth; 3, that of the *Sphinx ocellata;* 4, the grub of the *B. quercus*, already alluded to; and 5, successive views of the development of the egg of the Blowfly.

The form of the work is in folio; and the letterpress is given in Latin and German.

De Pulsu, Resorptione, Auditu, et Tactu: Annotationes anatomicæ et physiologicæ. Auctore E. H. Weber. Lipsiæ: 4to.—Schloss.

Some of the most curious questions in physiology are here treated by the distinguished professor of anatomy at Leipsic. We could wish the first of these subjects had been allowed a larger space and more ample discussion; but the tract on the sense of Touch

compensates for the scant measure given to Hearing, Pulse, and Absorption.

On the subject of *touch* we have here an account of the numerous experiments instituted by the author regarding the subtlety of that sense, and a summary of all that is authentic concerning its peculiarities. On our perception of the part touched; on our estimation of the weight of bodies; our sensations of heat and cold; and on the delicacy of the sense of touch as compared with that of our other senses, we have many admirable remarks made by the learned professor. Among the facts mentioned under the last head, there are one or two with which our readers may be glad to be acquainted.

The author considers it as a point worthy of special notice that the sense of hearing has in some respects a marked superiority over sight and touch in regard to acuteness and sensibility. Although the sight has such advantages in the clearness and subtlety of its perceptions, it appears that in observing minute differences it falls short of hearing. For example: M. Weber shows that by *touch* we cannot distinguish between the respective gravities of ponderable bodies unless they differ by $\frac{1}{15}$th, or at the very least, by $\frac{1}{30}$th of their weight. By *sight*, in order to distinguish a difference between two lines, one must exceed the other by at least $\frac{1}{100}$th part of its length. Whereas by the sense of *hearing* we can distinguish sounds from one another when they merely differ by the $\frac{1}{322}$d part of the number of vibrations.

The volume is dedicated to the sacred shade of Scarpa: "*piis manibus Antonii Scarpæ*"!

Theoretisch-practische Geburtskunde durch Abbildungen erläutert.—Midwifery, Theoretical and Practical: illustrated by Plates. By W. H. Busch, Professor of Midwifery in the University of Berlin.

The plates, which constitute the staple of this work, form an excellent collection: they are gathered from all quarters—Hunter, Maygrier, &c. as well as from original sources. The style of lithography in which they are executed is of the best sort; and we have no doubt the whole will form a very complete and valuable production.

Nosologie und Therapie der Chirurgischen Krankheiten in verbindung mit der Beschreibung der Chirurgischen Operationem. Von C. J. M. Langenbeck, &c. &c. Fünfter Band. Erste Abtheilung.

The excellence of Professor Langenbeck's work on Practical Surgery is too well known to need description. We merely notice it here to announce the recent publication of the first part of the fifth volume.

Lehrbuch der Chemie. Von E. Mitscherlich. Zweiter Band. Erste Abth. Berlin, 1835.—Schloss.

This is another work which is famous on the continent, and especially among chemists. The admirably simple and popular manner in which all the processes are detailed and illustrated with engravings, renders the Elements of Professor Mitscherlich the best production of the kind in any language.

MEDICAL GAZETTE.

Saturday, October 10, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE LANCET AND THE APPRENTICESHIP SYSTEM.

That the labourer is worthy of his hire is a sacred as well as a familiar truth. That the demagogue who lives on popularity, and sucks through the crooked quill of imposture the uncertain tribute of credulity and ignorance, earns hardly, and enjoys precariously, *his* reward, is a fact that history sufficiently attests. The mountebank must be ever on the move: when *known* in a neighbourhood, his occupation is quickly gone. Falsehood, in order to captivate, must surprise; and to maintain its empire, must be ever new. It is like those fireworks which derive their brilliancy from the rapidity of their revolutions; stop

them, and they are seen to be but sorry squibs.

Reflections like these must suggest themselves to the mind of any one who contemplates, even for a moment, the rise, the progress, and the present situation of the Lancet. The offspring of a lawless disregard for property, it has pursued from the instant of its birth one undeviating course of profligate indecency. Reckless of the truth, regardless of aught save the private interests and private passions of its owners and conductors, its honesty has been accident, its knavery calculation. Circumstances have made it liberal. As the many are those who can best pay their supporters, the many are its clients. They who openly laugh at even a decent regard for truth, can scarcely be supposed to entertain a very active perception of principle. Principle, indeed, and the Lancet, are twain—the moral antipodes each of the other. The monotony of its malignity was relieved at first, by some of those charms with which ability has the power of adorning vice. With much ribaldry and billingsgate, there was often humour, and sometimes wit. But the volatile spirit has evaporated altogether, and the *caput mortuum* that remains is unmitigated trash. Talent, at least literary talent, has departed; and the man of education must turn with disgust from the stupid vulgarity of its pages. Yet the same sordid thirst for personal gain—the same indulgence of vindictive passions, are as constant in their exhibition, and as palpable in their workings amid decay, as in the palmy days of the supremacy of that journal. It is with it as with the bawd that Horace loathed—unquenchable venom

"Sævit circa jecur ulcerosum."

That the circumstance which has more immediately called forth these remarks may be appreciated, it is proper to inform our readers, that, on the Saturday preceding the first of October, it is the custom of our contemporary to publish what he calls a "Student's Number." The name is probably, and properly, given on the *lucus à non lucendo* principle, because it is a number which students ought not to read. And yet it is a curious number, for on these occasions the worthy Editor is usually in the habit of "going the whole hog," if we may use that phrase, and outdoing even himself. It is really astonishing to see how many lies, and what gross absurdities, are packed in this cargo of calumny. First there is a preface—a summary of fabrications, and then there is a leading article, especially addressed to students, and, of course, especially false. But we leave the actual falsehoods for the present, in order to direct attention to one or two of the sentiments and exhortations, with which our contemporary insults the understandings of the students he affects to patronize. His pages on these occasions remind us of Richardson's booth at a country-fair. The senseless clap-traps strut up and down in the presence of the gaping multitude, and the prestige is crowned by a jig before the mob, in which Hercules and Pantaloon, the heroine in blue satin and she who pockets the cash, "go in and out and round about," to the delight and bamboozlement of the crowd below.

All who have thought much, we might almost say who have thought at all, upon the subject of medical education, have arrived at the conclusion that the present system of apprenticeship is decidedly pernicious. There has latterly arisen a disposition to abate that nuisance, and to do away with the palpable absurdity of confining a young gentleman for five good years

behind a counter, where he learns very little unless it be to label a bottle or a pill-box, and to make himself agreeable to his master's maid. But observe the light that has dawned upon the mind of our honest contemporary. He has suddenly discovered that the apprenticeship system is the beau ideal of human wisdom. He has discovered that it is not lectures—no, nor hospital practice—that can teach a student the principles of his profession; but this same calumniated system of apprenticeship, this it is, which constitutes the veritable Amphitryon; this it is which, under the new light, will rear the future Crichtons in medicine and surgery. To be sure, the *honourable* advocate of this antiquated abuse has at present the majority of thinking persons opposed to him, and is much in the situation of the bedlamite, who accounted for his chains and straw by the circumstance of the world and himself entertaining different opinions, and the world being able to outvote him. But it is not those who think, that the Lancet aims at pleasing, for they are the minority. Those who "take apprentices" are the mass of the profession, and, by flattery, they may be also got *to take the Lancet*. Look to this, parents and guardians! students, look to this! You whom the Lancet addresses and cajoles, you whom it advises—and advises, to betray—see your real interests offered up, without one feeling of compunction, to the Moloch of its cupidity! By us, and such as think and act with us, you have been rescued from the parchment bonds with which the ignorance of barbarous ages had bound you; will you suffer yourselves to be fettered again, that the miserable scribblers who subsist by that journal—the

"Heaven's Swiss who fight for any God or man—

may enjoy a little longer the wages of their literary prostitution?

It may be thought that we wrong our respectable contemporary—that it is a libel upon his unspotted character to attribute to him the preposterous idea of advocating the system of apprenticeships. We present his own words; and, unlike himself, we do not garble nor misquote.

"Why is the knowledge which the country surgeon communicates to his pupil treated as nought by the extortioners of our colleges and companies? It is one of the grossest insults that was ever offered to a body of educated men. By the existing regulations, all the medical students in the kingdom, unless they have paid certain sums of money to other schools where the system of folly and of falsehood is carried partially into operation,---all the students, without exception, we repeat, are treated as so many dunces,---as mere beginners in the rudiments of medical education. What doctrine does this inculcate to the community? Why, that those surgeons who take apprentices are incapable of instructing them even in the very elements of professional knowledge. Thus, in the course of years, they are deprived of those fees which they are entitled to receive from their apprentices, because parents and guardians, naturally enough, contend, that if the knowledge which the student derives during his apprenticeship does not *lessen* the expense of a medical education in London, the money paid for the pupilage in the country is, virtually, thrown away. Thus a flagrant robbery is committed on the great body of surgeons and apothecaries who are engaged in private practice, and a most shameful injustice is inflicted on the student, who, during his apprenticeship, and under the able and generous guidance and instruction of his master, has succeeded in obtaining a practical and scientific knowledge of his profession."

How absurd it is to suppose that lectures and observation at the bedside and in the deadhouse of a hospital, can teach a young gentleman what he learns "under the able and generous guidance and instruction of his master" in the country. Observe the peculiar advantages enjoyed by the apprentice. Anatomy is the foundation of surgery and medicine. What are our schools, with the amount of ca-

pital expended for the comfort and instruction of the pupils? what are *they*, we say, to some snug little corner in North Wales, where bodies must be plenty, and the facilities for dissection incomparably great? What are your hired lecturers and demonstrators, who devote themselves to teaching, if not to learning, the science they profess, to some generous master, the cares of whose family and fatigues of whose practice qualify him most admirably for affording anatomical instruction to his pupils? Can the paid attendance of a teacher in a dissecting-room be placed for an instant in comparison with the easy and familiar style in which a country surgeon, having finished his day's work, initiates the neophyte in the mysteries of the human frame? Oh, no! the student who would learn anatomy should go where there are no bodies, no dissecting-room, no museum, and no teacher. He would not acquire that vulgar information which would tell him the course and the relations of arteries, and nerves, and muscles; but he probably would acquire a much more subtle and refined sort of knowledge—such knowledge as we may suppose the *honourable* propounder of this new doctrine to possess in his own person.

We have instanced anatomy, but the parallel will hold equally with the other divisions of medical study. In all, the Lancet's reasoning will enable us to lay down this important axiom, that the best way to qualify a student is to strip him of every advantage. The less he sees and hears, the more he is to learn—a conclusion extremely reasonable in itself, drawn, we cannot doubt, from our contemporary's personal case and experience. He, we believe, enjoyed the advantages of an apprenticeship, and great were the fruits, in leading to a professional career, which may have been short, indeed, but which was certainly brilliant, as was convincingly proved a few years ago in a Court of justice*. Success equally signal will probably be the lot of those young gentlemen who are wise enough to follow the advice of so eminent an example, and so trustworthy a guide.

THE GOWER STREET PUFFERS.

We thought we had done with the wily trickery of the Gower Street stock-jobbers: we flattered ourselves that we had abated some of their overweening pretensions: but they have returned, we find, to their old habits again. No gentry calculate better than do the worthy proprietors on the value of advertising themselves in every possible shape, particularly at certain seasons: and we should not quarrel with them for this, if they only did it fairly and with good faith. Mark, however, what they have been doing this week, in the way of blowing trumpets on the opening of the session. Poor Mr. Tooke is, as usual, converted into a stalking horse or a cat's paw in the service. He hawks his "statement" into the market, complaining bitterly of ministers for not granting a charter to the self-styled university, to grant degrees—which, he says, they promised to do. Now this has evidently been contrived to lead the public to suppose that they, the Gower Street joint-stock company, still have a chance of such a charter, when they know in their hearts that such a pretence is a gross deception. Next comes *Professor* Malden, with a letter in the *Times*, to inform the public that, though the "University" may not have the power of *giving* degrees, it, along with King's College, will have the power of *taking* them; thereby insinuating that there was no chance for students getting degrees in London otherwise than by entering the respective establishments in Gower Street or the Strand. We are glad to find that the barefaced manœuvre of the "Greek" professor has not been suffered to go unreproved: the *græculus esuriens* will be more cautious for the

* In the trial which took place on the subject of the calamitous fire in Mr. Wakley's dwelling-house, a medical gentleman, who acted as his deputy during an absence of "about ten days," deposed that he had been called upon to attend but one patient, "a decent woman lodging in Avery Row!"

future. But the party know they have not much longer to carry on the game of deception, and are accordingly very desperate. The charter, which they know is destined for them, and which will take them down to their proper dimensions, changing their jackdaw title of "University of London" into "London College," will shortly be before the public, when it will be seen that they must stand henceforth on their merits alone, and on a precisely similar footing with the other schools of the metropolis.

OPPOSITIONISTS OF ST. GEORGE'S.

EPISTLE FROM DR. WILSON.

We cannot present the following letter to our readers without premising one remark, on the ridiculous *touchiness* of the writer; it can only be compared to the sensibility of a skinned eel. But let Dr. Wilson speak for himself: we shall append a few notes to his "*grandis epistola*," though we confess there are parts of it at the meaning of which we can only guess.

To the Editor of the Medical Gazette.

Sir,

It is with extreme unwillingness that I address any communication to a journal which, while encouraging attacks on personal character, withholds the name of its Editor, and thus renders itself irresponsible to complaint.

In justice, however, to others, I am compelled to correct certain statements relating to the School of St. George's Hospital, which appears in the "leading article" of the last number of the Medical Gazette. It is there assumed that a school of anatomy, designated as that of Kinnerton-Street, is especially connected with the school of medicine and surgery established in St. George's Hospital, of which hospital school your readers are led to believe that the Kinnerton-Street school forms a part. As a governor of the hospital, as one of its physicians, and as a teacher in its medical school, I beg to inform you that such connexion does not, and cannot, exist.

It is further stated, that the lectures lately established at the school immediately adjoining St. George's Hospital, in Grosvenor Place, have been "set up in opposition to those in the hospital." This your assertion, sir, in the spirit of the term "opposition," I utterly deny. The lectures on physic, on surgery, and on other branches of medical education, now given at the school in Grosvenor Place, were established, not in opposition to the lectures delivered at the adjoining hospital, but in defence of the anatomical school, threatened in its very existence by the concerted, yet active, hostility of one of the surgeons of the hospital, against which no security could be obtained from the majority of the medical officers acting with the individual to whom I have alluded, and myself, in committee on the affairs of the hospital school.

On the system of disparagement by implication, long pursued by you with respect to the anatomical school under my direction and that of Mr. Lane, I shall offer no remarks. Within the last few days you have been joined by an associate lecturer, in every way worthy of the same high mission.

The incorrect and injurious statements to which I have directed your attention, have already received a contradiction the most public and direct.—I am, sir,

Your obedient servant,
James Arthur Wilson.

St. George's Hospital,
Oct. 6, 1835.

Upon the intelligible parts of this communication we have only to observe—

1. That the charge of personality in the outset is wholly gratuitous; that there was any thing of a personal nature in the article which seems to have roused the chivalry of the Doctor, we totally deny. If, however, his gallantry extends to the protection of the *honourable* member for Finsbury, we must only cry him mercy.

2. As to the Doctor's fidgettiness to find out the name of the Editor of this journal, it only makes us smile at his simplicity. We long ago made up our mind that a public journal, in order to be conducted with impartiality, and to deal out even-handed justice to all parties, ought not to have an editor's name fixed on the wrapper; and we are not going to change our principles at the bidding of the valorous Doctor. If he thinks any of our statements slanderous, false, or libellous, he knows our publishers, and our printer: let him be content with that. Truth is independent of personality: though it may be convenient for Dr. Wilson and his friends

to turn aside from facts, to find out and fasten upon, if possible, a writer's name.

3. With regard to Dr. Wilson's assertion, that such a connexion as is represented in the Gazette does not exist between the hospital school and the school of anatomy, we have only to repeat our former statement (to which we refer), and to add, that what the Doctor says only proves that he has been misinformed on the subject.

4. The intimation that the lectures at Mr. Lane's school are not in *opposition* to those given at the hospital, is amusing. The matter stands thus: lectures on medicine, surgery, materia medica, &c., it is well known, have for several years been delivered in the theatre of St. George's Hospital (No. 1, Grosvenor Place); Dr. Wilson and others have been procured to lecture on the same subjects at Mr. Lane's house (No. 2, Grosvenor Place). This we were simple enough to think constituted what is commonly understood by an "opposition;" but Dr. Wilson says it does not: of course we must bow to his decision.

The rest of the letter we do not understand, and therefore cannot pretend to answer. Dr. Wilson, however, appears to charge us with having in some manner disparaged his school,—which we directly and positively contradict: we merely spoke highly of the excellent, and, we are happy to learn, most flourishing establishment in Kinnerton-Street,—if, indeed, that can be construed into disparagement of the "opposition" school!

A word at parting. As we happen to know from experience that the worthy Dr. Wilson and his friends rejoice in a prodigious *copia verborum*, and that discussions on this subject cannot be very interesting to the general reader, we beg to decline further contributions of this nature; but venture to suggest instead, that *the long-promised* PAMPHLET (see the letters of Messrs. Lane and Co., published some months back in this journal) may serve the purpose of the whole party, in opening up all their grievances to a sympathizing world.—Ed. Gaz.

MUSEUMS AND HOSPITALS OF PARIS.

M. Orfila, as Dean of the Faculty of Paris, has just visited Holland. He went through the museums of Utrecht and Leyden, in the latter of which he had an opportunity of viewing the combined collections of Albinus, Raw, Bonn, Bruckmann, and other eminent anatomists. The object of the Dean has been to gather information on the modes of preparing practised in the Dutch cabinets, as well as to ascertain what may be wanting for the new "Museum Dupuytren," which it is intended shall be the richest and grandest in Europe. In visiting the hospitals of Rotterdam, the Hague, Amsterdam, Breda, and the towns already mentioned, M. Orfila is said to have gathered much useful information respecting the best mode of pursuing medical studies, which no doubt he will turn to account, as the project of law of the French government regarding medical education is still on the tapis.—*Journ. Hebdom.*

GUACO A REMEDY FOR GOUT AND ASTHMA.

In the year 1788, Mutis, a Spanish botanist, learned from an Indian the preservative properties of the guaco against the bites of serpents. He and his friends tried it, by inoculating some of the Indians with the saliva of a venomous serpent, in which the presence of the poisoned fangs was ascertained. One of the party was also bit in the hand. The application of the leaves of the guaco arrested the occurrence of consequences which would otherwise have been fatal. The Indians regularly inoculate themselves with juice of guaco to protect the system from serpent bites; the juice is also taken internally, by way of reinforcing the inoculation. The guaco is said also to be efficacious where hydrophobia is apprehended. In arthritic pains, gout, convulsions, tetanus, and other disorders, the guaco is said to act as a specific; but the list of affections in which it is boasted to be beneficial is so heterogeneous, that little confidence can be reposed in it.—*Casper's Wochenschrift.*

NEW DIVISION OF THE ANIMAL KINGDOM.

M. Ehrenberg has lately presented to the Academy of Sciences, Paris, a new plan of dividing the animal kingdom into twenty-eight classes, founded on organization. M. de Humboldt, who explained M. Ehrenberg's system to the Academy, stated that twenty-two of the twenty-eight classes were of the invertebrate animals,

which are divided into *cordata* and *vasculosa*, according as they are possessed or are destitute of a heart. In the latter the vessels offer no pulsations, and the rapid movement of the fluid within them is promoted by the oscillation of the internal walls. The digestive organ is either simple, as in the *tubulata*, or multiform, as in the *racemifera*, the lowest classes of which having ciliæ and hermaphrodite organs, constitute the *infusoria* or *polygastrica*.

In the course of two expeditions which he made (one in Syria, Nubia, Dongola, and along the shores of the Red Sea; the other in the north of Asia, and about the Caspian Sea), M. Ehrenberg had an opportunity of observing a vast number of these organizations. But the plan of dividing them now suggested he by no means considers as perfect; he merely proposes it as an essay susceptible of development and *perfectionnement*.—*Gaz. Médicale.*

HAHNEMANN AND HIS DISCIPLES.

The French government has licensed Dr. Hahnemann, the founder of homœopathy, to practise his profession in France. It is doubtful whether his disciples in the capital will retain the due respect for their master, who is now become their rival.—*Gaz. des Hôpitaux.*

ASPHYXIA OF INFANTS IN THE BIRTH.

M. Baudelocque announces that he has saved the lives of two children, footlings, whose heads remained long engaged in the pelvis. The plan adopted was to introduce into the mouth a silver sound of sufficient capacity to permit the entrance and exit of air in the act of respiration.—*Gaz. Médicale.*

LONGEVITY OF BIRDS.

A wild goose was lately shot at Schievenhorst, near Dantzic, having round its neck a metallic collar, on which was inscribed the date 1800.—*Gaz. des Hôp.*

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE III.

OPERATION OF MEDICINES BY SYMPATHY.

IN my last lecture I mentioned two ways by which it may be presumed the remote effects of medicines are produced—namely, absorption and sympathy. Having fully discussed the first mode of operation, I proceed in this lecture to examine the second.

Some medicinal agents affect remote parts of the body, under circumstances which do not authorize us to conclude that they act by absorption; such substances are said to operate *by sympathy*. Let us inquire into the meaning attached to this expression.

All the different parts of an organized being have certain relations or connexions with each other; which are divided into three kinds or varieties,—the mechanical, the functional, and the sympathetic. It frequently happens that one organ in the performance of its functions exercises a mechanical influence over another. Thus the motions of the respiratory muscles have an important influence over the circulation of blood within the chest. By the contraction of the muscles of the fore-arm pressure is made on the deep-seated veins, and the passage of blood through them thereby obstructed. These, then, are evident and clear cases of a *mechanical relation* between certain organs. We have also numerous instances of what I have called *functional relations*; but one example will suffice: the liver cannot secrete bile if the supply of arterial blood, or of nervous energy, be cut off: hence it is evident that the function of the liver depends for its performance on the proper execution of the functions of the arterial and nervous systems.

But there is a class of relations which cannot be referred to either of the preceding heads, and which are called the *true sympathies*, or the *sympathetic relations*. Thus if we titilate the mucous membrane of the nose, sneezing is produced; if the soft palate, vomiting. These are but two out of many instances in which relations exist between organs connected neither mechanically nor functionally. We know not how sympathies are maintained; the membranes, the cellular tissue, the blood-vessels, and the nerves, have each in turn been charged with this office; but none of these modes of explanation are free from objection. The most plausible hypothesis is, that the nervous system is the seat of sympathies; but the difficulty in admitting this supposition arises from the evident proofs of sympathy which exist in vegetables, beings not known to possess nerves, or a nervous system. Dutrochet, indeed, asserts that the small points, or spots, observed on the cells and vessels of plants (figs. 16 and 17), are analogous to the nervous globules of animals; he calls them *nervous corpuscules*, and regards them as the scattered elements of a diffused nervous system. That globules are found in vegetables in the situation described by Dutrochet no one can deny; but the grounds on

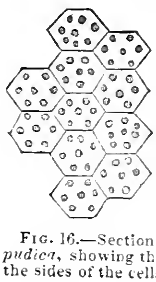

FIG. 16.—Section of the medulla of the *Mimosa pudica*, showing the globular bodies adhering to the sides of the cells.

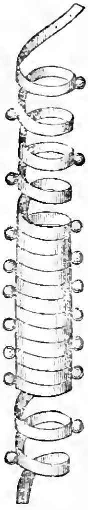

which he asserts they are nervous, are slender indeed. The researches of Leeuwenhoek, Prochaska, Fontana, Sir Everard Home, Bauer, the brothers Wenzel, and Dr. Milne Edwards, have shown that the nervous system of animals is composed essentially of agglomerated globular corpuscules. Here is a drawing (fig. 18) representing the globular cells of the pulpy matter forming the brain of *Limax rufus* (red slug), and of *Helix pomatia* (the great or vineyard snail), molluscous animals of the class *Gasteropoda*. Observe the corpuscules on the sides of the cells. Here, says Dutrochet, is a structure evidently similar to the medullary tissue of vegetables; and the analogy extends beyond the mere physical characters, for we find the two structures agree in their

FIG. 17.—Spiral vessel found in the stems of *Solanum tuberosum* and *Cucurbita pepo*, with the adhering globules.

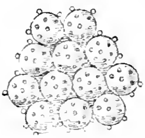

FIG. 18.

chemical properties: the globular corpuscules both of animals and vegetables are rendered opaque by boiling in nitric acid, while a solution of potash restores their transparency. These corpuscules, then, are regarded, by the before-mentioned celebrated physiologist, as the organs producing the nervous power.

In the lower classes of animals which have no nerves—namely, the zoophytes—we meet with a kind of diffused nervous system. Here is a magnified representation of one of the arms of a *Hydra* (fig. 19), showing the distribution of the nervous corpuscules. In this animal, the *Vorticella convallaria* (fig. 20), these corpuscules are much less numerous, but are still observed; they occupy the central part of the branches.

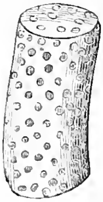

FIG. 19.

On these grounds, then, Dutrochet assumes that the little globules sticking to the cells and vessels of plants, and which are nothing but particles of amylaceous or resinous matter, are to be regarded as the scattered elements of a diffused nervous system. Two facts seem to disprove his hypothesis: first, plants that do not offer the least trace of animal sensibility have globules in as great abundance as those vegetables (*Mimosa pudica*, for example) that really appear to possess it; and secondly, those plants which offer the strongest symptoms of sensation are not those that

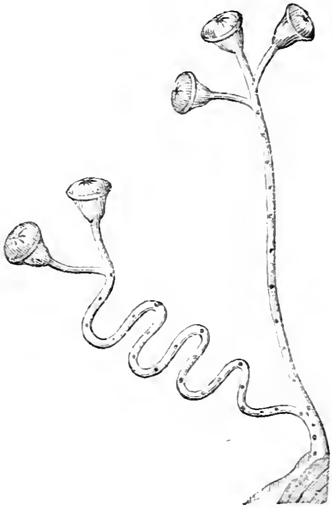

FIG. 20.

approach the nearest to zoophytes in structure. I think, then, we may say with Bichat that the causes of sympathies are completely unknown: a dark veil still conceals from us the agents of communication which connect the organs from whence the sympathetic influence is conveyed, to the part which receives it.

Four circumstances lead us to infer that particular substances produce certain remote effects on the system, independently of absorption; these are as follows:—

1. The instantaneous operation of some medicines.

2. The remote effects not being in proportion to the absorbing power of the part.

3. Dilution diminishing the remote action.

4. Mechanical injury affecting remote organs.

1. Observe the instantaneous effect of strong hydrocyanic acid. I apply the nose of a rabbit to the mouth of a receiver, filled with the vapour of this acid, and you see the animal is instantly killed. In this and other cases the operation is, I think, too quick to admit of the supposition that absorption was the cause of the phenomenon. Sir Benjamin Brodie has remarked, that he once happened to touch his tongue with the end of a glass rod, which had been dipped in the essential oil of bitter almonds; and he says that he had scarcely done so, before he felt an uneasy indescribable sensation in the pit of the stomach, great feebleness of limbs, and loss of power to direct the muscles, so that he could hardly keep himself from falling.

2. Orfila found that alcohol acted with

much less energy when injected into the cellular texture than when taken into the stomach; and as the power of absorption is greater in the former than in the latter part, he concludes that the remote action of alcohol must be produced by the agency of the nerves. Opium, on the contrary, is supposed to operate by absorption, because it is more active when injected into the cellular texture of the thigh than when taken into the stomach.

3. The effect of dilution on the action of medicinal and poisonous agents oftentimes assists us in determining the mode by which the remote effects take place. Thus if we apply a strong mineral acid to the stomach, great disorder of the general system is produced; but if we dilute the acid previous to its exhibition, little disturbance in the system is observed. Now as dilution facilitates absorption, it is improbable that the constitutional disorder caused by swallowing strong mineral acids depends on their absorption. On the other hand, Dr. Christison has shown that oxalic acid, considerably diluted, quickly enters the blood, and causes speedy death; hence it is presumed to kill in consequence of absorption.

4. Mechanical injuries sometimes give rise to effects on remote parts similar to those caused by the action of certain medicines or poisons. Laceration of the stomach produces similar constitutional disorder to that occasioned by the strong acids.

The action of medicines by what authors call *continuity* and *contiguity* of organs is only an example of sympathetic operation. By irritating the mouth of the excretory duct of a gland we promote excretion; and by applying clysters or suppositories to the rectum, we excite secretion and contraction in the intestinal tube above the rectum: these are examples of the action of medicines by *continuity* of organs. When we give aloes, hellebore, or savine (substances which irritate strongly the lower portion of the large intestines) to affect the uterus, or when we employ demulcents to lubricate the pharynx and œsophagus, and thereby to alleviate cough, we are acting on the principle of *contiguous* sympathy.

Peculiar Effects of Medicines.

Having now discussed the question as to how the remote parts of the system become affected, I proceed to examine the *locality* and *quality* of the effects of medicines; and

First, of the *locality* of the operation. Most medicines have some one or more organs on which they exert their especial influence; and in consequence of the mechanical, functional, and sympathetic relation which this organ has with the other organs of the body, the whole system becomes, in a secondary way, more or less disordered. These are the *Specifica topica* of Hufeland. Dr. Christison has justly remarked, that there are few substances which affect primarily and simultaneously many parts of the body: arsenic and mercury, however, do appear to have this effect. The following are instances of parts specifically affected by medicines:—

1. The brain, by the substances commonly called narcotics and inebrients.
2. The spinal marrow, by the substances containing strychnia and brucia, to which we may probably add mercury and lead.
3. The circulatory organs, by stimulants, tobacco, arsenic, digitalis, &c.
4. The lungs, by tartar emetic, emetia, corrosive sublimate, &c.
5. The alimentary tube, by some emetics and purgatives.
6. The urinary apparatus, by diuretics, cantharides, &c.
7. The skin, by some diaphoretics.
8. The salivary glands, by mercury, and also sometimes by hydrocyanic and nitric acids, opium, arsenic, fox-glove, &c.
9. The mucous surfaces, by mercury, turpentine, balsam of copaiba.
10. The lymphatic system, perhaps by mercury and iodine.
11. The organs of reproduction, by ergot of rye, cantharides, phosphorus (?), and some of the substances denominated emmenagogues.
12. The liver, probably by mercury.
13. The throat, by belladonna.

This list might be much extended, but it is difficult to satisfy one's mind in many cases; and, indeed, in this list I have inserted several substances whose operation on the parts mentioned, though generally believed, has been less satisfactorily proved. Many remedies disorder several of the functions of the body, but it is sometimes not easy to determine which was the first effected.

Secondly, of the quality, or nature, of the effects produced by medicines.—Theoretically we can easily conceive that the functions of the system may be influenced in two ways—namely, *quantitatively*, or in respect to the *degree* of their action; and *qualitatively*, or in reference to the *nature* of the action induced. It is, however, difficult to select pure and unequivocal instances of either mode of operation solely, since most medicines give rise to simultaneous quantitative and qualitative changes.

Dr. John Brown, the ingenious author of the *Elementa Medicinæ*, assumes that all medicines are stimulants, differing only in

the degree of their operation. His views may be thus explained: all living beings possess a peculiar principle, termed *excitability*, and which distinguishes them from inanimate bodies. Certain agents, called by him *exciting powers*, act on the *excitability*, and thus maintain life, or, in the language of Brunonism, produce *excitement*. Whatever can modify the excitability, and produce a greater or less degree of excitement, are termed *stimulant powers*. Hence, therefore, medicines, like other external agents, are stimulants; some of them causing excitement of the whole system, others of a part of it.

The author of this doctrine also assumes that medicines differ from each other in little more than the degree in which they exert their stimulant power;—so that digitalis, hydrocyanic acid, cinchona, mercury, opium, alcohol, cold, and even bloodletting, are all stimulants, differing only in degree. But what right have we to assume all medicines or other agents, stimulants? Where is the evidence of this stimulant effect when we apply strong hydrocyanic acid to the tongue of an animal, and thereby produce instantaneous death? Is it not absurd to suppose that alcohol, mercury, cinchona, and opium, differ in the *degree* of their operation only? The apparent effects produced are so dissimilar, that we are compelled to suppose a difference in the *nature* or quality of their operation.

These difficulties in the way of the Brunonian doctrine led some physicians of Italy to modify it; and thus arose the *theory of contra-stimulus* of Rasori, Borda, and Tommasini. Some medicines, say these writers, stimulate, others have a contrary power: the first they call stimulants, the second contra-stimulants. Is this term contra-stimulant synonymous with sedative? Certainly not; for sedatives, properly so called, are those substances which produce a depressing action upon the system in a state of health. Now a contra-stimulant is a substance which merely counteracts a state of excitement, and the term, therefore, becomes applicable to many bodies whose action is unequivocally stimulant. Perhaps our word antiphlogistic is most analogous in its meaning to that of contra-stimulant; but by the Italian physicians would not be regarded as synonymous, for according to their notions contra-stimulants diminish excitement, by depressing the excitability of the fibre by a kind of specific property, which no one thinks of assigning to our antiphlogistics. The difference between the two, however, is after all only theoretical. The test of the contra stimulant power of medicines is their obviating or counteracting the effects of some well-known and well-characterised stimulant. Thus alcohol is put down as a stimulant, and hence any agent which relieves the inebriation produced by it, is denominated a contra-stimulant. Proceeding in this way, then, we may form the following classification:

Stimulants.	*Contra-stimulants.*
Caloric.	Cold.
Opium.	Bloodletting.
Musk.	Metallic medicines.
Camphor.	Emollients.
Phosphorus.	Tonics.
Æther.	Ipecacuanha.
Ammonia.	Purgatives.
Wine.	Hydrocyanic acid.
Alcohol.	Digitalis, belladonna, stramonium, &c.
Carbonic acid.	
The electric fluid.	Nux vomica.
Aromatics.	Valerian.
Cinchona (by some this is regarded as contra-stimulant.)	Coffee.
	Mustard and pepper.
	Cantharides.
	Turpentine.
Red particles of the blood.	Squills.
	Nitre.
Animal food.	Acids and oxygen.

A slight view of this table will convince you that many of the substances put down as contra-stimulant are, unequivocally, stimulant; for example, cantharides, turpentine, &c. In fact, the founders of this doctrine have assembled under the same head, bodies of the most opposite effects; and have separated others, whose general operation is very analogous. They appear to me to have totally disregarded the physiological or immediate, and to have directed their whole attention to the therapeutical or secondary effects, which, as I shall hereafter have to show, are accidental and uncertain. They assume the existence of certain diseases, which are called *sthenic*, because they are produced by too much stimulus, and suppose the existence of *contra stimulants*, because certain agents sometimes relieve this state. In other words, these physicians judge of the nature of a disease by the effect of the curative means, and of the virtues of medicines by the nature of diseases. So that if a disease now supposed to be *sthenic* should hereafter prove to be *asthenic* (that is, produced by too little stimulus), the medicines used would then immediately pass from the class of contra-stimulants to that of stimulants!

The hypothetical notions of the Italian physicians have, however, led to some practical advantages in the treatment of diseases, and taught us that the system will oftentimes bear much larger quantities of medicines than had been supposed. According to their views the doses ought to be proportioned to the degree of excitement; for when inflammatory

action runs high, the patient will bear very large doses of contra-stimulants without any obvious evacuation from the skin, stomach, or bowels, and the disease will be subdued wholly by the contra-stimulant effect upon the fibres, and other solids of the body. This capability of bearing increased doses has been called *tolerance* of medicines, and has led to their exhibition in much larger quantities, and at shorter intervals, than had previously been practised, and which in several cases, (especially that of tartar emetic in peripneumonia) has been attended with great success. Thus, instead of giving one-eighth of a grain to three grains of this antimonial salt, they have administered it to the extent of a scruple.

I now proceed to offer a few remarks *on the circumstances which modify the effects of medicines;* a subject which is of considerable importance, and which would become of great practical use, were we better acquainted with it. Frequently, however, the causes of the modifications observed are enveloped in the deepest obscurity; and in other cases, though we may by experience refer certain results to particular causes, yet we cannot in the least explain the mode of agency of the latter. The following are some of the leading circumstances that influence the operation of medicines:—

1st. *Variations in the doses of medicines* are sometimes attended with variations in the effects produced. Thus, in small repeated doses, oil of turpentine acts as a stimulant or excitant to the general system, and in a large dose, as a purgative.

2nd. *Variations in the mechanical and chemical properties of medicines* also modify their effects. Thus, sulphuric acid in its concentrated form acts as a caustic, but not so when largely diluted. Morphia is more active in solution than in substance.

3rd. *Habit.*— Experience has proved that by repetition metallic substances seldom lose, but, on the contrary, seem rather to gain an increase of power by repetition. Habit or custom will not, I believe, enable a person to increase to any great extent the dose of arsenic or of mercurials; yet the very reverse of this is found to hold good with respect to many medicines obtained from the organic kingdom, especially narcotic and inebriating substances; of the diminished effects of which we observe good examples in opium-eaters and drunkards. Habit enables the Turk to swallow two drachms of solid opium at a dose; the *bon vivant* to take his two or three bottles of wine at a sitting; and the sailor to chew large quantities of tobacco, which in the unaccustomed would be attended with powerful effects. Dr. Chapman tells us that he knew a wine-glassful of laudanum to be given several times in the twenty-four hours. "But what is still more extraordinary," says this author, "in a case of cancer of the uterus which was under the care of two highly respectable physicians (Drs. Monges and La Roche) of Philadelphia, the quantity of laudanum was gradually increased to three pints, besides a considerable quantity of solid opium in the same period." Pinel mentions a lady who required 120 grains of opium to give her ease in cancer of the uterus.

In what way are we to explain these phenomena? Some think that the effect of habit is only an increased power of decomposition, on the same principle that, by repetition, the stomach often acquires an increased facility in digesting substances which had at first resisted its assimilative powers. If this explanation were correct, we ought to observe the effect of habit principally when substances are swallowed, and little, or not at all, when they are applied to a wound, to the cutis vera or other parts not possessing a digestive or decomposing power;—and the common dose of opium ought to have the usual effect, when applied to any part of the body of an opium eater, except the alimentary tube. I am not prepared to say positively whether this would or would not take place, but I suspect the result of the experiment would be a disproval of the hypothesis. The ultimate fact, then, to which we can reduce our inquiries as to the effect of habit, appears to be this, that by repetition, the body (or certain parts of it) becomes less susceptible to the influence of certain organic agents.

We must not pass over a curious fact sometimes observed by the repeated use of certain substances, namely, that effects are obtained different in their nature from those caused by only one or two applications. For example, no one could by observation of the effect of one or even two doses of opium have anticipated that great emaciation, debility, and even premature old age, could be brought on by the long-continued use of large doses of this substance.

4th. *Climate.*—That climate has an important influence over the functions and even physical characters of the body, every one will admit; and we presume that the same agent may influence the action of medicines, by rendering the system more or less susceptible of their influence. It is, however, difficult to select pure and unequivocal instances of this. Calomel has been given in much larger quantities in India than it is customary to exhibit it in Europe, and as the effect was not proportioned to the dose, it has been presumed that the climate of India diminishes the susceptibility of the system to the influence of this agent; an inference,

however, which, although it may be true, can hardly be said to have been proved.

5th. *Diseased conditions of the body.*—Diseases of various kinds sometimes have a remarkable influence in modifying the effects of medicines; and hence it is of considerable importance in practice to be acquainted with these facts. One of the most striking instances is that of the diminished influence of opium in tetanus. A scruple of this substance has been given at one dose, and repeated every two or three hours for several days, without any remarkable effects being produced. To what cause we are to attribute this I know not. The late Mr. Abernethy mentions in his lectures, a patient who had tetanus from a wound which he received at the time of the riots in the year 1780, to whom a scruple of opium was given every day, besides a dose of a drachm at night: when his body was opened, 30 drachms of opium were found undissolved in his stomach. You might perhaps infer from this case that the diminished effect arose from the want of solution of the medicine; and that this was Mr. Abernethy's opinion seems presumable from his advice as to the mode of using it in this disease. "Give it," says he, "repeatedly in small doses, so that it may liquefy." However, that it was not the want of liquefaction or solution seems proved from the fact that laudanum is also less effective in tetanus than in health.

Begin, in his *Traité de Therapeutique*, relates that M. Blaise, in a case of tetanus, administered in ten days, four pounds, seven ounces, and six drachms of laudanum, and six ounces, four drachms, and forty-five grains of solid opium! Begin endeavours to explain these facts by assuming that the stomach acquires an increase of assimilating power, so that it is capable of digesting these enormous quantities of opium, in consequence of which their usual narcotic effects do not take place. He supports this hypothesis by stating, that if, during tetanus, opium be injected into the veins in much smaller quantities, it produces its usual effects. If, however, this latter assertion be correct, it does not at all warrant Begin's assumption; and bearing in mind that opium administered by clysters during tetanus is less powerful than usual, and also taking into consideration the case related by Mr. Abernethy, I think we have evidence sufficient to warrant our non-admission of this hypothesis. All, therefore, apparently that can be said in the way of explanation is, that in tetanus, the nervous system has undergone some change by which its susceptibility to the influence of opium is considerably diminished.

Another example of the influence of disease in modifying the effects of medicines is seen in the diminished power of mercury during fever. I have repeatedly seen large quantities of mercurials exhibited internally, and in some cases accompanied with mercurial frictions, without exciting salivation; and in general such cases terminated fatally. I never saw a case of fever in which salivation was established (and I have seen several) that died; but whether the recovery was the consequence of the mercurial action, or the salivation of the recovery, I will not pretend to say, though I must confess I have formed a favourable opinion of the efficacy of mercury in some forms of fever, especially those complicated with local congestion or inflammation.

6th. *Mental influence.*—The effects of medicinal agents on the body are very much influenced by the state of mind. Hufeland tells us that he knew a lady who, having conceived a violent aversion to clysters, was thrown into convulsions by the injection of a mixture of oil and milk. I have several times seen the most violent effects attributed to bread pills, which pills the patients had been previously told exercised a powerful influence over the system.

7th. *Age.*—Living beings are incessantly undergoing changes; so that at different epochs of their existence their organization and actions are somewhat different. Thus they increase, develope themselves, arrive at maturity, and lastly decrease. We may conveniently admit four ages of man,—infancy, youth, the adult age, and old age,—each of which is marked by particular states of the functions, by a tendency to certain diseases, and by a different susceptibility to the influence of medicines. As a general rule, infants require much smaller doses than youth, and the latter than adults. This is particularly remarkable in narcotics, which require to be exhibited with the greatest caution to infants: while the more active metallic preparations, as the salts of lead, nitrate of silver, arsenic, &c. ought perhaps never to be given to them. However, infants appear to be less (or certainly not more) susceptible to the influence of calomel than adults; constituting here a remarkable exception to the general rule.

Attempts have been made to lay down a general rule for determining the doses of medicines for children, but none is applicable in all cases. Dr. Young says, that for children under twelve years of age, the doses of most medicines must be diminished in the proportion of the age to the age increased by twelve. Thus, at twenty-one, the full dose may be given, but at two years only $\frac{1}{7}$.

$$\frac{2}{2+12}=\frac{1}{7}$$

Hufeland gives the following scheme:— At the end of the first year suppose the dose to be 1; then at the fifth it will be 2; at the fifteenth 3; and at the twenty-fifth 4. Suppose the dose for an adult to be 40 grains, for other ages it will vary thus—

Years.	25	20	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
Doses.	40	35	30	29	28	27	26	25	24	23	22	21	20	18	16	13	10

Months.	11	10	9	8	7	6	5	4	3	2	1	½
Doses.	9		8		7		6		5	4	2	1

8th. *Sex* has also an influence on the operation of medicines, females being much more susceptible than males.

9th. The *nature of the part* to which the medicine is applied has an important influence over the effect produced. The stomach, for example, is much more susceptible than the skin. Opium acts more powerfully on the serous than on the mucous tissues. Carbonic acid acts as a positive poison when taken into the lungs, but as a grateful stimulant when applied to the stomach.

10th. *Individual peculiarities.*—Under this head we may examine three kinds of peculiarities; 1st, those that affect whole nations or communities, and which constitute the differences between the human races: if I might be allowed to coin a new term, I would call these *racic peculiarities;* 2ndly, those peculiarities called the *temperaments*, which affect certain individuals without reference to the races, and which consist in disproportions in the development or activity of certain organs by which the whole animal economy is influenced; 3rdly, *Idiosyncracies*, or those peculiarities which affect the functions only of organs, and which are not common to a number of individuals.

In the first place let us notice the influence of *peculiarities of race or of nations.* It is not necessary for me to enter into an examination of the peculiarities (structural and functional) of the human races or of individual nations. It is quite sufficient for me that such do exist, and are obvious to the most careless observer. *A priori* there would be little difficulty in admitting that these may be accompanied with modifications of the susceptibility to the influence of exterior agents, such as medicines. As, however, we meet with differences of customs, manners, diet, climate, &c. among different races, or even nations of the same race, so it is difficult to determine what we ought to refer to the influence of these, and what to the peculiarities in organization. Hence we are not in a condition to offer pure and unequivocal instances of the peculiarities of race affecting the operation of medicines.

Differences of *temperament* are said to affect the influence of medicinal effects. But what is temperament? This term is derived from the Latin verb *tempero*, to mix together, or to temper, and is applied to certain conditions of the body formerly supposed to arise from variations in the proportions of the fluids of the body. Thus, when the fluids were in proper relative proportions, they were said to temper each other, and by so doing produce a perfect temperament. When the yellow bile was supposed to be in excess it produced the choleric or bilious temperament; when black bile, the atrabilious or melancholic; when blood, the sanguineous; and lastly, when pituita or phlegm, the pituitous or phlegmatic. Although in modern times physiologists do not admit this theory of the ancients respecting temperaments, yet we cannot help acknowledging that certain individuals offer physical and functional peculiarities of the kind described by the ancients under the above mentioned heads: and thus the existence of temperaments has been generally admitted, while the theory or explanation of them has varied with the prevailing medical doctrines of the day.

The number of temperaments has not been agreed on; Hippocrates admitted four, Boerhaave eight, others five. Under five heads I think we may include the leading varieties, which will then stand as follows:—

1st. The *nervous* temperament, characterized by great susceptibility of the nervous system, and comparative little muscular power.

2d. The *sanguine* temperament, known by great development of the vascular system. The functions are performed with considerable activity, but the strength is soon exhausted.

3d. The *muscular* temperament is characterised by great development of the locomotive organs (bones and muscles); but accompanied by diminished nervous energy.

4th. The *relaxed* temperament, marked by deficiency of power and imperfect performance of all the functions, with a soft and flabby condition of the solids.

5th. The most *perfect* temperament is that in which all the organs and functions are properly balanced, and in which we have the greatest strength.

Each of these temperaments varies in regard to its susceptibility to the influence of medicinal agents. In the sanguine temperament stimulants must be employed

very cautiously: in the nervous and relaxed temperaments, evacuants can only be used with great attention and care.

The effect of *idiosyncracy* (a term derived from ἴδιος *proper*, σὺν *with*, and κρᾶσις *mixture*) in modifying the effects of medicines and poisons is in general to increase their activity. Thus, some individuals are peculiarly susceptible of the action of opium, some of mercury, and others of alcohol. The odour of ipecacuanha will in certain persons produced short and difficult respiration, approaching almost to a paroxysm of asthma. The late Mr. Haden has related a case in which two drachms and a half of tincture of colchicum produced death: the mother of the patient was also exceedingly susceptible of the action of colchicum even in very small doses. There are, however, instances in which the effect of idiosyncracy is to diminish the activity of medicines; some persons, for example, are exceedingly insusceptible of the action of mercury.

A PAPER

ON THE

APPLICATION OF COMPARATIVE ANATOMY TO HUMAN EMBRYOLOGY,

Read before the Junior Physical Society, Guy's Hospital, May 2d, 1835 *.

By John Anderson, M.E.S.
Late Clinical Clerk, Guy's.

Some apology is necessary for introducing a subject which may appear at first sight foreign to the usual discussions in this society; but still more will an apology be necessary for the very imperfect manner in which that interesting subject will be submitted to its notice, and the presumption (I may almost say) on my part, in at all venturing upon so diversified, so intricate, an investigation.

It is scarcely necessary to observe that the objects and meaning of comparative anatomy are the anatomical and physiological investigation of the lower animals, and a comparison of their structures with the same structures in man,—the results of such investigation and comparison forming an unerring foundation for the systematic zoologist, and marks of identity for the inquiring geologist, exposing and unfolding numberless physiological facts to the natural historian, and enriching and perfecting by comparison our knowledge of human anatomy, physiology, and pathology, the ground-work and basis on which the superstructures of medicine and surgery are built up and supported, the links by which they are indissolubly compacted and united. These subjects are, however, so diversified and extensive, that it behoves me to confine myself entirely to a comparative consideration of the essentially important organs and systems (those of generation purposely excepted), and to adhere rigidly to some fixed plan. In accordance, then, with the one which, as possessing the greatest general interest, I have thought it most expedient to pursue, a two-fold object has been attempted. I propose, in taking a review of the whole animal kingdom, to illustrate, as they present themselves, the analogies and progressive phases of development of the human embryo, premising these by a momentary elucidation of systematic technicalities and classification, and a few remarks on the advantages to be derived from the study and pursuit of comparative anatomy. To do justice to these propositions, I must trespass on the time, and entreat the patient hearing, of the society.

Many illustrious names, from the earliest ages, may be ranked amongst the promoters and followers of comparative anatomy; many highly-talented names of recent and present date may be mentioned as its enthusiastic advocates, contributing, by their unwearied and patient investigations, to improve a science which, until lately, has advanced with but reluctant progress. Will it be out of place here to mention the splendid monograph of Mr. Bell on the

* I feel it necessary (to my more immediate friends especially) to explain the motives that have induced me, after so long a delay, to publish this paper, which is word for word the same as that read before the Society in May last. From a variety of circumstances, which it is unnecessary here to notice, I was induced, after reading that paper, to extend it, and alter its form, before publication in the Medical Gazette; but in prosecuting the investigations, and making the necessary dissections for that purpose, time has rapidly passed away, and I have been so led on by the extreme interest and variety of the subject, as to render the mass of facts even now accumulated much too large for insertion in any periodical; and thus I have been induced to abandon the idea of adding to the original paper; with the view, however, of publishing those facts, and the results of my recent observations, in a different form and distinct title of "Researches in Comparative Anatomy and Human Embryology." Under these circumstances, therefore, I have considered it better not in any way to disturb the original arrangement; and will conclude these remarks by requesting the indulgence of my readers in perusing this very imperfect and superficial paper, assuring them, at the same time, of the substantiation of many assertions here made, in the work in which I am at present engaged, together with many new and I trust some important facts collected from actual dissections, in a series of which I am still occupied, and to some of which I shall take the opportunity of referring in this communication.

testudinata, the accurate investigations of Mr. Morgan on the generative system of the kangaroo, and the invaluable lectures of Professor Grant on comparative anatomy and physiology? Sir Charles Bell observes *, "Comparative anatomy is but the means of preparing us for other branches of the profession," and it is in this light, and not as an abstract science, that we, as students of medicine, are to consider and pursue it; and of this we may be assured, that when engaged in these attractive investigations, there will be unfolded to our view many beautiful phenomena, many otherwise hidden truths, and a multitude of facts with which to store and invigorate the mind; to impress it, as Cuvier observes †, with a habit of order and precision, to accustom our powers of observation to vigorous exercise on all occasions, to lay up a rich and solid foundation-store of human anatomy and physiology. How necessary are all these acquirements for us in our professional career! With how many advantages, then, may we pursue that science which I now venture to introduce to the notice of the society. But again: where is the link whereby the fundamental connexion of comparative anatomy with the sciences just mentioned is formed?—it is in its application to human embryology; it is this that constitutes the essence of its import, and the value of its researches to the student of human anatomy.

In endeavouring, however, to demonstrate the facts just enumerated, I regret my necessity to make use of certain terms that to some may not be familiar. With a view, then, to their elucidation, and a hope of increasing the general interest of my subject, I will detail a hasty and general survey of the animal kingdom, referring to the denominations of the leading classes, and the characters by which those denominations are supported. In taking this survey, the most superficial observer would find many general points of interest, many beautiful illustrations of the relation of organization and instinct, many physiological analogies, to arrest his attention; he would be struck with a certain degree of similarity pervading the construction of animals, and the end and aim of their existence; he would see, indeed, that the whole animal kingdom was an extensive chain of beings, every link being perfect, every gradation being strictly, though almost insensibly, apparent: so that from man, "the type of animal perfection," a general and gradual decrease of organization, of perfection, of development, takes place—chasms that formerly existed being now filled up by geological discoveries; breaks that still remain affording matter of stimulating interest to the industrious naturalist and scientific geologist.

Again, on taking only a general survey of the organization and nature of animals, we find four principal forms, four general plans, on which they are constructed. The first form is that where a bony case or shell protects and encloses the brain; a chain of bones proceeding thence protects the spinal marrow; and from these, ribs, varying in number, protect the viscera. Added to this, a mouth, with two jaws, senses distinct, sexes separate, red blood and a muscular heart, characterize a large group of animals, with man at their head, to which the name of Vertebrata has been applied. They are subdivided into *mammalia*, viviparous animals, suckling their young, and *aves*, or *birds*, which are oviparous; both these classes have a heart, with four cavities, and hot red blood. *Reptilia*, which are oviparous, have a heart with only three cavities, and cold blood. These three classes breathe by means of lungs. *Amphibia*, animals undergoing a peculiar metamorphosis, having a heart with only two cavities, and breathing at first by means of gills. Lastly, *pisces*, or *fishes*, undergoing no metamorphosis, having a heart of two cavities, and breathing by means of branchiæ. These classes are subdivided into orders, founded principally on the form and position of the teeth and the structure of the feet. The second form comprises animals with no skeleton, but of a soft muscular texture, in which occasionally are inclosed plates or shells; the digestive apparatus is tolerably complex; two organs of sense only are discoverable: they are called Mollusca. Amongst them we distinguish the *cephalopoda*, so named from the feet surrounding the head, as the common *sepia*. The *pteropoda*, having wing-shaped membranes for swimming, as the *clio borealis*. The *gasteropoda* inhabit univalve shells, and have a sub-abdominal muscular disk, upon which they creep, as the *snail*. The *conchifera* inhabit bivalve shells, and are always fixed to them. The *tunicata* have their internal organs tolerably developed, and are surrounded externally with a soft transparent tunic. Most of these animals are inhabitants of the sea. The third group, familiar to us in the forms of insects and worms, comprises animals with articulated membranes, and breathing by lateral tracheæ; their external covering is hard and horny, or soft and

* Lectures on the Hunterian Preparations, delivered at the College in 1833; published in the Lancet, vol. i. 1833.—Vide Lecture I., p. 285; the concuding paragraph of which contains strong proofs of the advantages to be derived from comparative anatomy.

† Preface to the first edition of his Règne Animal.—See also a letter addressed by Cuvier to Mertrud, in his Leçons d'Anatomie Comparée.

annulated; their jaws move laterally. From their form they are called Articulata, and are divided into *crustacea*, having a solid calcareous covering, compound eyes, and two pair of antennæ. *Arachnida*, or *spiders*, with no antennæ. *Insecta*, a magnificent tribe of animals, the study of which alone has engaged the attention of the most profound talents, the most illustrious characters. I could wish that time would permit me to dwell on the beauty, the infinite variety, the instinct, the external appearance, the internal conformation, of this splendid, this numerous tribe. They are distinguished by undergoing an interesting metamorphosis, having six legs, antennæ and spiracula for respiration; they are found in every corner of the globe. The *myriapoda* are characterized by a number of feet, as the *centipede*. The *annelida* are surrounded by rings, as the *leech*. The *cirrhopoda* inhabit multivalve shells, and have feet of a curled form, as the common *barnacle*. The minute *rotifera* are distinguished by their circles of ciliæ and wheel-like form; and the *entozoa* are animals found in the interior of the body, and familiar to us under the forms of hydatids and intestinal worms. The fourth and last form comprises animals whose organs of sense and motion are arranged in a radiated manner: they are called Radiata. Amongst them are the *echinodermata*, animals having a spiny skin, and a complex internal organization, as the *echinus*, or *sea-egg*. The *acalepha*, which are of a gelatinous form, and excite inflammation of the skin when touched, as the various forms of *medusæ*. The *polypiphera*, or *zoophytes*, have digestive cavities in a soft fleshy substance, and a calcareous concretion either externally or internally; they have a great analogy to, and some were indeed formerly figured as, plants. The *porifera*, or *sponges*, have an external porous surface, leading to internal ramifying canals. And lastly, the *polygastrica*, minute microscopic animals, having an amazing number of stomachs. Many of these classes are inhabitants of the sea.

Having taken this hasty survey, I pass more immediately to the object of my paper. The comparative development and perfection of the organs of support and of digestion, the nervous, circulatory, and respiratory systems, will come successively under consideration; and I set out with presupposing a complete anatomical knowledge of these parts in their perfect and complicated state. I suppose also that we are familiar with the varied external appearance and configuration of the human embryo, according to its age, and the peculiarities of the full-grown perfect fœtus.

It is a singular but beautiful physiological fact, that organic matter generally should be developed and called into being, should obey the same laws and rules of development, should become more complex and perfect in the same gradual manner, in which man individually, from the first germ of his existence to his perfect form, exhibits;—that the animal kingdom, from its minutest microscopic point of vital endowment, should pursue an analogous perfection of development of different organs, should exhibit the same systems, mutually dependent or rising into or out of each other, that are called into operation in rapid succession during the short nine months of human embryotic and fœtal existence;—that we ourselves, in embryo, should lead a similar aquatic life to many of these animals. I repeat it,—it is a stupendously beautiful fact of analogy, that in every living animal, from the lowest zoophyte to the highest quadruped, a certain degree of organization, or development of every structure, whether taken individually or collectively, is found, that will correspond with the development and temporary perfection of the same organ, or organs, in man, in all his different stages, from the embryo upwards. Thus, when we reflect upon our own complex organization, we are struck with the fact, that in the development of our organs, the evolution of our systems, the formation of our structures and tissues, we demonstrate a rapid and magnificent succession of objects illustrative of the whole animal kingdom. To prove this will now be my humble endeavour.

The impregnated human ovum, when first detected, consists of a thin membrane inclosing a quantity of transparent limpid fluid. The time at which it enters the uterine cavity is variously stated by various authors, some mentioning eight days*, others sixteen†, others twenty‡. The embryo is first visible in about three weeks, but according to Meckel in five days §. Now the lowest speck of animal life with which we are acquainted, the *monas termo*, one of the Polygastrica, seems to furnish us with a similarity in form and structure to the human ovum, it also being in the form of a minute vesicle, consisting of a delicate membrane inclosing a transparent fluid. Thus, then, in the very onset, the two extremes of animal organization present a similarity in external configuration and internal structure ‖. These Polygas-

‡ Dr. Ramsbotham's Lectures on Midwifery, Med. Gaz.

§ Dr. Blundell's Midwifery, by Castles.

‖ Concerning the interesting subjects mentioned so cursorily in this paragraph, but which time then prevented me from further noticing, I have collected some valuable information from the most eminent authors; and as regards the

trica are minute animals of a soft texture, inhabiting fluids of various kinds: this corresponds with the gelatinous aquatic condition of the very early human embryo, when no trace of earthy matter is perceptible, and when imbedded and surrounded by the water of the amnion. Their substance is made up, as it were, of an infinite number of appendices, cavities, or stomachs, the structure of which the recent investigations of Professor Ehrenberg have more clearly demonstrated. Some of them have only one aperture for the reception of food and excretion; others have an oral and an anal aperture.

The organs of support in the Porifera, or sponges, present us with a pleasing analogy; they consist of minute spiculæ of various forms imbedded in a texture of some firmness, and composed either of silica, of carbonate of lime, or of a peculiar horny matter. In the human embryo we find nuclei of ossific matter deposited in various parts, in a similar manner, and each point of calcareous matter following a uniform and constant methodical arrangement of deposition. Again, in the very early human embryo, no internal cavity I believe exists; and this is the case with these and the preceding class of animals in their early and gemmule state; but as the former proceed in development, minute openings and internal ramifying canals are formed, through which currents of water are constantly circulating. The same takes place in the latter class, only that the ramifying vessels are more superficial, and the currents of water are excited by the rapid vibration of ciliæ placed on the surface of the animal; thus, then, is nourishment afforded by the animalculæ which the water contains, are oxygenation and renovation of the vital properties effected, by the air which is in this simple manner circulated. This uncomplicated state of things will at once bring us to the earliest embryo condition of the human body, where there are found only similar anastomosing ramifying vessels (derived from a simple one proceeding from the amnion), simply circulating fluids, without any contraction or peculiar action of the vessels themselves, or without any development of a central cavity. No nervous filaments have as yet been detected in either of these classes of animals, though they certainly appear to be under the well-directed guidance of nervous sensibility; nervous globules, however, are everywhere diffused through the cellular tissue of their body*. Precisely the same occurs, I presume, in the earliest condition of the human embryo.

Proceeding with the Polypiphera, the next class: in some the skeleton consists of a horny substance, situated either external or internal to the secreting fleshy part, which is itself permeated by calcareous spiculæ, reminding us again of the formation of bone in the early human embryo, and especially the white calcareous points in the young cranium. In others again, as in the *corals*, the skeleton is composed of an earthy substance—either silica, carbonate, or phosphate of lime.

The digestive apparatus presents us with a greater complexity of development, and diversity of form, than in the preceding classes. Some, however, as the *hydra*, or common fresh-water polypus, have only the simple form in them described; others have the mouth prolonged, or developed into a number of tentacula; and the ciliæ with which they are fringed having a vibratile motion, create a current of water, and thus attract such a prey of animalcules within its vortex as is necessary for food and subsistence, and for the proper aeration of the cellular texture of their body. Some again, as the *flustra*, have a distinct cæcum appended to the alimentary canal, this forming the first rudiment, the first approach, to a chylopoietic gland; for Dr. Grant supposes that this cæcum may be the origin of the liver†. Now this gland I have found well developed in the early fœtus of the *mus musculus* (common mouse), *erinaceus europæus* (hedgehog), and *felis catus* (domestic cat), of immense size in the human fœtus at the fifth month, the tenth and seventh week; and as most physiologists consider it to be in some way or other instrumental in the development of the fœtal body, we may infer that it is of exceedingly early formation: allowing this, therefore, and judging from analogy, may not its rudimentary condition and primary development be even the same as in these Polypiphera? Again, the forms of stomach in the classes of animals just related have an analogy to what is considered the embryo development of the human stomach, which probably is at first little else than a fold inwards of the external tunic; or, reasoning from Andral's descrip-

primary form of organized matter, the analogies of its development, and the manner in which the progressive advances of this latter phenomenon take place, according to geometrical principles, I hope to bring forward some of the highly important, and to this country somewhat novel, opinions advanced by Carus in his Anatomie Philosophique, a work abounding in elaborate and scientific research.

* On this subject Dr. Roget, in his Bridgewater Treatise, makes some valuable remarks.

† Lectures on Comparative Anatomy and Animal Physiology. In this first quotation from Dr. Grant's Lectures, I will take the opportunity of stating how much valuable assistance I have derived from their perusal and study; in fact, they have been my guide throughout.

tion *, a pouch formed by the continuation inwards of the vesicula umbilicalis; and this pouch or cavity, equally in the early human embryo as in these low zoophytes, may be considered as the only well developed organ; but, in the more complicated forms of the Polypi just described, we find the alimentary canal composed of a distinct membranous tube, open at both extremities; so, in a little more advanced state of the human embryo, do we find a similar tubular cavity existing. Andral observes †, " the intestinal canal is one of the first organs of which any trace is perceptible; at first it is only a continuation of the vesicula umbilicalis, which gradually elongates itself into two tubes,—one inferior, constituting the large intestine; the other superior, forming the small intestine and stomach." Others, however ‡, assign a different situation (the cæcum, for instance) to the origin of the intestinal canal §. Sanguiferous vessels, and circulatory currents of fluids and globules, have been observed in many of these Polypi; but their nature does not seem well determined. Nervous globules are abundantly distributed, and nervous filaments are supposed here to exist, but only by analogy.

Proceeding with the Echinodermata, some are covered with a dense integument, of a leathery consistence, and have a power of forming for themselves adventitious coverings of shells or sand. Others, as the *asterias*, or star-fish, have the rays, or framework of their body, composed of small osseous pieces; others, as the *echinus*, have the body invested by a shell, or calcareous crust, armed with spines, and a mouth with five teeth. The genera of this class present numerous forms and transitions of the digestive apparatus, and in them its increased complexity is well demonstrated. In the star-fish there are radiating ramifying canals, or cæca, extending into each division of the body, terminating in little sacs, and having their origin in a central stomach, which alimentary canal, again, has but one opening for the reception of food and the discharge of excrement, though in the higher classes it terminates by a distinct anal orifice. In the common *echinus esculentus* we find an œsophagus, developing a stomach, and an intestinal canal having no ramifying cæca, but supported by a mesenteric membrane, and terminating in a cloaca, or general cavity for reception. Here an analogy may be noticed: the cloaca (according to Andral) exists in the human fœtus a few months before birth; and I have myself observed it at the fifth month, and tenth week. Again, in the early human embryo, at first but one opening to the alimentary canal can be supposed to exist, and that the tubular communication with the vesicula umbilicalis, which, according to Velpeau, contains a nutritive fluid contributing to the development of the embryo; but as this development progresses this communication ceases, the alimentary canal becomes more extended and perfected, though straight, and, it is scarcely necessary to observe, oral and anal orifices are formed. In examining a fœtus of about nine weeks, I distinctly traced a cord, independent of the intestine, running from the vesicula umbilicalis to the under part of the stomach.

As regards the nervous system, the entrance of the alimentary canal is surrounded by a circular nervous cord, giving off filaments in various directions, each of which has its origin marked, as in the Acalepha, by a minute ganglionic enlargement. In the mesenteric membrane before noticed is a distinct vascular system, comprised of numerous ramifying minute capillaries; these anastomosing form a larger circular trunk, which surrounds the stomach; in some this trunk is longitudinal, which then gives off lateral branches. The same occurs in the human embryo: the ramifying vessels before described, by anastomosing, enlarge into a trunk, a simple canal, which gradually dilating, is the first rudiment of the heart.

The respiratory organs are of a tolerably complex structure; for, in the Holothuria, the water for the aeration of the blood enters by the cloaca, or anal orifice, passes through two large vessels, and then circulates through a number of smaller ramifying capillaries over the whole of the body; these may be considered as internal branchiæ, and are apart and separate from the vessels for circulating the blood.

Thus, then, in the Radiata, the lowest group of animals, many pleasing analo-

‡ Oken and Geoffroy St. Hilaire.

§ The primary evolution and gradual perfection of development of the alimentary canal is a subject of the highest possible interest: and the structural changes that take place during its passage from a simple tube to a highly-complicated state of organization and formation, are well demonstrated in the metamorphosis of the Amphibia. This fact I was led to notice from repeated investigation; and having at length demonstrated these changes by dissection, I shall have some very interesting results to communicate on this head in my little work. These remarks will equally apply to the nervous, circulatory, and respiratory systems; and, indeed, I am quite sure, that insignificant as the Amphibia might appear to be, their internal anatomy is of the first importance, and that the degraded frog, if minutely investigated from its first escape from the ovum, would tend to throw great light upon a subject which, in this country, has so little engaged the attention of scientific individuals.

gies have presented themselves, and the rudiments of many important structures have already been demonstrated. The similar commencement of ossific deposit, and the analogies of the digestive cavities, are interesting; the early development of the vascular system, highly important, inasmuch as it governs the formation of other structures, and immediately regulates the growth of the whole nervous system, the varied parts of which we shall presently find developed in a corresponding ratio with the particular distribution of the arterial system *.

We now pass to the Articulata, the first class of which comprises animals whose habit and more immediate connexion with some of the diseases of the human body claim for us almost a double share of attention. I mean the Entozoa; under which class are arranged the different forms of hydatids and intestinal worms, parasitic inhabitants of the bodies of other animals. Some of the *ascaris* are provided with a dense external covering, transversely striated or articulated; others have sharp-pointed spines; others, called *epizoa*, have a skin much more dense, articulations more perfect, and a rudimentary development of legs, antennæ, and maxillæ. In the *hydra*, a species of hydatid, we find a simple digestive cavity, with but one aperture, capable of distention, when it has the appearance of a thin, white, transparent bag. In the *tænia* there are two communicating alimentary canals. In the *ascaris* I found the alimentary tube passing straight from mouth to anus; dilated in places, and in the middle third completely imbedded and surrounded by a leash of filiform tubes†. All the species have sharp spines, or rudimentary teeth, and many of them are well known to infest the human subject. A minute Nematoid Entozoon, inhabiting human muscle, has been recently described by Mr. Owen ‡; it first occurred in this hospital, and was then introduced to the notice of the profession by Mr. Hilton §. The formation and origin of tubercles have been by some imputed to a species of hydatid ‖. The nervous system in these Entozoa shews itself in the form of a fine, white, opaque streak, consisting of a double nervous filament without ganglia, extending the whole length of the body, and encircling the œsophagus. This is highly interesting, from the similar rudimentary condition of the nervous system in the human embryo; where, as in all other animals (the sympathetic nerves being first demonstrable), the spinal cord is formed before the brain. The first visible rudiments of a brain and spinal marrow appear in the fœtus (according to Tiedemann *) between the fifth and sixth week, in the form of a whitish vesicular fluid, contained in a membranous canal or tube in the trunk, leading to or forming a cavity or pouch in the head. At the seventh week the spinal cord (in consequence of the early development of the intercostal arteries) is large and thick, the rudiments of the two lateral columns of which are manifested in the form of a simple, pulpy, white streak — a nervous streak, according to Dr. Grant, precisely similar to what has just been described in the Entozoa; a groove in the posterior part marks the penetration of the pia mater; its structure is minutely globular†. The pre-existence of a nervous system in the form of globules has been before hinted at; these globules increasing and uniting form sympathetic ganglia ‡. Arteries and veins are distinctly traced, ramifying through the body of these parasitic animals, and, in the higher forms, a distinct pulsating cavity or vessel is demonstrable. In this way is a colourless nutritive fluid circulated, and this again oxygenated by the cutaneous transpiration of the fluids of the animals, in which they live. Here, again, may an analogy, a similar progress of development, be traced. We have seen that at first, numberless ramifying inactive vessels, without any central enlargement, circulated the vital fluids equally in

* This description of the Radiata is, it must be confessed, excessively deficient in originality, from my not having been able to procure at that time any marine animals; since then, having had the opportunity of collecting on the sea coast, I have been able to verify many of these statements by dissection, the results of which will be fully detailed subsequently.

† Subsequent dissection has, however, proved to me that there was only one long convoluted tube, the ovary of these animals.

‡ In a paper read before the Zoological Society. See Med. Gazette for April 25th, 1835.

§ In a paper read before the Medico-Chirurgical Society. See Med. Gazette for Feb. 2, 1833.

‖ Having mislaid my notes on this subject, I am unable to give the direct quotation; but the paper appeared in a number of the Lancet not further back than two years ago. The author was a Frenchman.

* Anatomy of the Fœtal Brain; a most elaborate work, with exquisite plates from nature.

† Though I have dissected fœtuses of an early age, I have not yet been able to demonstrate any portion of the nervous system; and, indeed, not having had the opportunity of immersing them in alcohol when recent, this could hardly be expected. I have now, however, some very early fœtuses of the squirrel, mouse, sheep, &c. hardening in alcohol, in which I hope to be more successful. Should this fail, the artificial incubation of the egg will probably afford some opportunity for dissecting the spinal cord in its earliest state, the development of which is undoubtedly the same in birds as in the human species.

‡ The manner in which the globules both of the nervous and vascular systems arrange themselves, according to geometrical principles, to form a pervious or impervious tube, is beautifully detailed by Carus, in his Anatomie Philosophique.

the early human embryo as in the lower radiata, and progressing simultaneously, an inactive dorsal vessel was formed. Now in these higher Entozoa, a central pulsating vessel has been demonstrated; so in the human embryo, at the fourth week, is a pulsation perceptible which is known to be the beating of the heart *.

Passing over the Rotifera and Cirrhopoda, from want of time, and as not illustrating much progressive development of the human embryo†, we come to the Annelida, or red-blooded worms; some of which, as organs of support, have the power of laying extraneous layers of shells or sand, others of exuding from their body a calcareous secretion, forming a tube of various shapes; others have hard spines, of a horny consistence. The digestive apparatus, in some, consists of a simple, partly dilated canal, with two openings; others, as the leech, have three jaws set with sharp teeth, and a membranous stomach divided into large communicating cells. In the *lumbricus terrestris* I found the intestinal tube presenting a sacculated form. The nervous system consists of a double longitudinal cord, united in two or more ganglia; the development of which, and the distribution of the filaments, depending on the complexity of organization and structure. These are the only invertebrate animals that have red blood; it contains, however (according to Dr. Grant), but little fibrin, and circulates in a double system of vessels—viz. a dorsal arterial trunk and two returning abdominal veins. Here we find, apparently for the first time clearly demonstrable, but still existing more or less in all the articulata, distinct venous trunks for the return of blood; the same, we may presume, takes place in progress of development in the human fœtus, and demonstrable, we may conceive, in the rudimentary vena cava, which I have myself found in the fœtus of nine weeks. The organs of respiration in some of these worms present branchiæ resembling tufts, attached either to the anterior or middle and back part of the body; others respire by means of air-sacs opening from the side, as in the leech.

Having spoken of the helminthoid, I now pass on to the Entomoid Articulata; noticing the Insecta, Myriapoda, Arachnida, and Crustacea, conjunctively. These all possess articulated members, the rudiments of which were perceptible in the preceding class: this may be considered as analogous to the primary bud-like development of the extremities of the human embryo, and their subsequent increased protrusion and elongation. In a fœtus of eight weeks I found the anterior extremities 1-12th of an inch long, the posterior appearing only like hemispherical tubercles; at ten weeks they both measured 5-8ths of an inch in length. The bodies of these entomoid animals are protected and inclosed in a hard, elastic, solid case, composed of a peculiar principle called *chitine* by the French, and either the carbonate or phosphate of lime, or both: in the Insecta there is scarcely a trace of carbonate of lime, while in the larger Crustacea it is very abundant. This skeleton or case is exuviable, to allow of the animal's growth; it is composed of a certain number of articulated rings, or segments, the rudiments of a perfectly developed vertebral column in the higher classes, the analogue of its development in the human embryo, where we can conceive the tubular canal before spoken of to have become more consolidated by cartilaginous and slight bony deposit. The digestive apparatus varies much in form, being tolerably simple in the Myriapoda, but in the Insecta we find a pharynx, œsophagus, crop, a muscular toothed gizzard, a stomach, and complicated intestines. In the dissection of some neuropterous larvæ, I observed these parts tolerably distinct; the intestinal canal was short and nearly straight, the gizzard and true stomach were supplied with a beautiful plexus of nervous filaments *. Most of the assistant chylopoietic glandular organs were present—viz. liver, pancreas; and these forming a beautiful rudimentary illustration of the same organs in the higher classes, and it is reasonable to suppose also in the human embryo. The form and structure of the mouth are very various; it is armed with huge-toothed maxillæ in some †, furnished with a delicate perforate proboscis in others ‡, and set with little laminæ, in the form of setæ, in those that live by suction §. The Arachnida and Crustacea being animals of a true carnivorous nature, have the alimentary canal short and straight; in the common edible crab I found the œsophagus and intestinal canal very short, the latter curved forwards, and the stomach curved with teeth. The nervous system in most of the true Insecta, Cuvier describes ‖ as consisting of

* Physiological Observations in Lizars's Anatomy and Cyclopædia Americana, article *Embryo*.

† These classes will be fully treated of in my subsequent investigations.

* Larvæ of *libellula depressa, agrion*, &c. These are carnivorous feeders. I have more recently had the opportunity of dissecting some vegetable-feeding insects (*melolontha, cetonia*, &c.), where the construction of the alimentary canal, biliary vessels, &c. was quite different.

† *Cicindela, carabus, libellula*, &c.

‡ *Papilio, sphinx, phalæna*, &c.

§ *Cimex*, &c.

‖ Règne Animal, translated by Griffiths.

a brain placed on the œsophagus (formed by two ganglions united at the base), giving off eight pair of nerves and two single ones, and of twelve ganglia, all inferior *. Here, then, we find a supra-œsophageal nervous accumulation; in fact, an imperfect brain demonstrable, and in the hymenopterous insects its division into hemispheres becomes first apparent. This we know to correspond with the progressive development and situation of the fœtal brain; the globular fluid in the cranial cavity before described, becomes similarly condensed to that in the spinal column; in the course of time (according to Tiedemann) two membranous pouches, the terminations of the pyramidal cords, form the rudiments of the two hemispheres, the various convolutions and cavities becoming subsequently demonstrable. In the Arachnida the ganglia are fewer, the nervous system is more concentrated, and holds, as it were, an intermediate condition of development between the Insecta and the Crustacea, in which latter class it presents itself in the form of simple abdominal filaments, which, increasing in development (with thoracic ganglia) coalesce into one great nervous accumulation in the centre of the body. The vascular apparatus is upon the same plan as in the other articulata, only that the dorsal vessel in the Insecta is divided into eight chambers, each having a contractile power, separated from each other by two converging valvulæ, which prevent the blood from retrograding and communicating by fissures with the abdominal cavity; the ultimate distribution and circulation of the vital fluid do not appear well understood, as no ramifying capillary vessels can be traced †. These are, however, better marked in the arachnida, where, indeed, the whole sanguiferous system is more highly developed. In the lower Crustacea, the head is only a lengthened dorsal vessel, but in the higher ones it consists of a fleshy ventricle placed on the back; from this the blood is transmitted to the different parts of the body; whence it is sent to the branchiæ, and then back again to the heart. Let us now turn to the vascular system of the human embryo: we have already traced its origin and progressive development up to the formation of a central and pulsating cavity; still progressing, we now find that a distinct muscular cavity is formed (analogous to that in the Crustacea), to be afterwards divided and subdivided to form the complex perfect heart of the hot-blooded Vertebrata. The respiratory organs in Myriapoda, Insecta, and Arachnida, consist of tracheæ or elastic vessels, which, receiving air through stigmata pierced in their sides, distribute it by infinite ramifications to every part of the body. In the Neuropterous larvæ before mentioned, I found this beautifully illustrated; two dorsal tracheæ, united by a transverse one, gave off in the thorax lateral tracheæ, opening externally by stigmata, and terminated in the abdomen by a complete leash of air-tubes. Some of the higher Arachnida respire by true air-sacs, and in the Crustacea there are branchiæ variously situated and protected, receiving air from openings in the skin. Rapid strides of advancement in the evolution and increased development of the various organs and systems have been made in these Articulata. A perfect external skeleton has been formed, the digestive apparatus has become complicated, a nervous system well established, and the vascular and respiratory systems more determined and concentrated. It may be interesting also to state that the first appearance of tubercular deposit in the lower animals, takes place in the larvæ of some Insecta *, and that a minute *acarus* has been lately found to exist in the vesicle of the itch †.

[To be continued.]

* All these parts, I am glad to say, I am now able to shew, by dissection, in the larva of *dyticus marginali*, of a species of *arctia* (Leach), &c. I am now working upon this beautiful tribe of animals, and have yet several interesting species to examine.

† In recently reading Carus, however, I find that he has discovered the circulation of the blood in the larvæ of some Neuroptera (*agrion puella*), &c.; which important fact he made known at the meeting of German naturalists at Dresden, in 1826. See, on this subject, his memoir Entdeckung eines einfachen, &c. Leipzic, 1827; his memoir in the Isis, 1828, p. 477; and his Traité Elémentaire d'Anatomie Comparée, translated by M. Jourdan, vol. ii. p. 319.

* I cannot recollect the direct quotation, and I have searched through various books for the original statement of the fact, but without success. I have a faint idea that it was in the larva of the *pontia brassica*, but am not at all certain.

† See, on this subject, the Medical Gazette for October 4, 1834, and the Medico-Chirurgical Review for January 1835. For the original description, see the Mémoire Comparatif sur l'Histoire Naturelle de l'Insecte de la Gale; by F. V. Raspail: Paris, 8vo.

OBSERVATIONS

ON A

FATAL CASE OF CONFLUENT SMALL-POX,

OCCURRING IN THE ADULT.

To the Editor of the Medical Gazette.

Sir,

Should the following observations upon a case of small-pox taken from my case-book, appear worthy a place in your valuable journal, from having a

tendency to elicit information from persons more competent than myself, their insertion will oblige, sir,

Your humble obedient servant,

SAM. J. JEAFFRESON,
M.B. Cantab.

Arundel St. Strand,
Oct. 7th, 1835.

I was called upon on Wednesday, Sept. 2d, to visit W. K., (a previously healthy individual of about 28 years of age) whom I found to be labouring under small-pox. The eruption first made its appearance on the evening before my visit, having been preceded by barely eight-and-forty hours of premonitory fever, not of a very severe kind. The eruption became confluent upon the face and extremities; the earlier part of his complaint was attended by no very extraordinary symptoms; there was, however, for some days a discharge of blood by stool; but as this was kept within due bounds, I did not think it desirable to check it by any very active means. About the 8th or 9th day he began to flag; his tongue being brown and his pulse feeble; with delirium. Small quantities of port wine and beef-tea were now given him, and he was ordered ʒiss. doses of Huxham's Tincture in an effervescing saline draught every six hours, with an opiate at night.

Under this plan he was going on remarkably well, when on the 14th (the 13th day of eruption) I was sent for to see him in the morning, his friends considering him worse. I did not, however, see him till noon; he had then become much more comfortable: it was ascertained that he had not had a very good night's rest. His tongue was now tolerably clean and moist; his pulse 110, of sufficient strength; bowels and urine natural; skin warm; wandering *slightly* in his mind, but retaining a perfect recollection of me, and consciousness of what was going on around him. The only symptom upon which I looked with any degree of suspicion, was that the pustules on the arms and legs, (which had run a good deal into each other in places, and so had become very extensive) were remarkably and suddenly fallen in. He was ordered to continue his bark, wine, and beef-tea. I saw him again in the afternoon, about half-past four: he was still going on well, and his pulse remained so steady that I requested them not to give him more wine unless he appeared to get lower, till my visit in the morning; but a powder at bedtime, consisting of 7 grs. of Dover's powder, and 1 gr. calomel.

An intelligent medical friend who saw the patient this morning considered him to be going on so well as to be nearly out of danger.

15th. Half-past 9 A.M.—The patient died at about 8 this morning. His friends stated that after I left him last evening he became more delirious; this, however, subsided in a short time after taking the powder; he then became calm, and expressed his conviction of his approaching fate; he afterwards "got a *comfortable* night's rest;" awoke at about 6 o'clock, and "went off without a struggle."

REMARKS.—What, it may be asked, was the cause of death? I regret that circumstances would not allow of my making a post-mortem examination, which might have thrown some light upon this subject; but I think it must be allowed that the symptoms during life did not indicate sufficient lesion of any one organ to have caused the fatal termination of this case. Delirium, it is true, had been present for some days, but it had not been of a very severe character, and was rather on the decrease than the increase; and, indeed, was absent for some time previous to his death. Would this have been the case if congestion or other cerebral lesion had been the cause of death? It cannot be supposed that active mischief within the thorax or abdomen could have been present to a sufficient extent to have proved fatal, without having given rise to some symptoms during life.

Be it remembered that he died on the 14th day of the eruption of confluent small-pox. May not exhaustion alone have been sufficient to destroy life? It may be said that this does not appear probable from the report of the day before; but it should be borne in mind that that report was made after he had taken stimuli, and that these stimulants had not been used from 4 o'clock of the previous afternoon up to the hour of his death. This, then, would give rise to the question, might the administration of stimulants on the morning of the 15th have prolonged life? Possibly they might.

But I incline to think that the fatal termination of this case was owing to other circumstances; circumstances

which would probably have defied the scrutiny of the morbid anatomist's scalpel—an instrument which, though it has greatly advanced medical science, too often, I fear, aims at laying down the exact bounds of structural lesion which are consistent with the preservation of life. It will be remembered that the only symptom which I considered unfavourable on the 14th was the sudden falling in of the large pustules on the extremities; a symptom which Dr. Gregory, the accuracy of whose observation is only equalled by the extent of his experience, considers highly unfavourable. Within twenty-four hours, then, of this circumstance the patient dies. Now it is a fact that the variolous pustule contains a poisonous matter capable of communicating the disease by inoculation; and it is a reasonable conclusion that if these pustules suddenly fall in, (their containing cuticle remaining entire) the greater part of their contents must have been reabsorbed into the system. Considering, therefore, the severe effects which succeed the introduction of the variolous poison (whether by infection, contact, or inoculation) into the system of a previously healthy and strong individual, can it be wondered that the sudden absorption of so large a quantity of this virus into the system of one worn down by sixteen days' severe illness, should itself be sufficient to cause death?

Supposing, therefore, the fatal termination in this case to have been owing to such a cause, it becomes a question of much interest, how similar cases (for it does not follow that all cases are similar—that is, owe their fatality to this cause) may be treated with the most reasonable hopes of success.

I think the objects to be attained may be considered under three views:—viz.

1st. To prevent the reabsorption of any, or at least of a great portion, of the noxious matter.

2dly. If absorbed, to enable the constitution to bear up against its baneful effects; or,

3dly. To administer (if any such exist) some principle which shall have the power of destroying, or at least diminishing, the injurious tendency of the variolous poison.

1st. Might not the first object be in part obtained (in instances like the present, when the pustules run much into each other) by puncturing them, and thus letting out their contents? This plan has, I believe, been adopted on a small scale on the face, not with the object now mentioned, but for the purpose of preventing the scars.

2d. This object will be obtained by generally supporting the system, and needs no further observation here.

3d. Whether any substance with which we are at present acquainted has the specific power of destroying or diminishing the virulence of the variolous poison, I will not upon my own experience pretend to say. This power has, indeed, been attributed to acids and to mercury; the latter of which, when rubbed up with the small-pox virus, has been shown to destroy its power of communicating the disease. If, therefore, a specific be found whose administration is safe, it would appear to be a particularly desirable remedy in such cases where the principal danger is threatened rather from the malignant nature of the disease than from any structural disorganization to which it may give rise. This idea is followed up further on.

Mrs. K.'s baby, 6 months old, was ordered to be vaccinated immediately on my first seeing her husband; this was, however, by some accident delayed until the following day (the 5th of fever, and 3d of eruption) The vaccination succeeded perfectly well; and although the child was exposed night and day to the influence of the infectious atmosphere, both before and after vaccination, yet it escaped without any illness whatever. This circumstance (and similar ones are not uncommon) leads me to reflect that possibly the introduction of the vaccine virus into the system at an early period of small-pox, might have the effect of modifying this disease. I am not aware that this plan has ever been tried, nor have I had opportunities of trying it myself; but I cannot see any reason why the experiment should not be made with safety. Since writing the above I have met with two cases where variola and cow-pox ran their course simultaneously in the same individuals, which, at all events, would lead one to suppose that this experiment is practicable. One of these cases is recorded in the Lancet by Mr. Macnee, in which confluent small-pox and cow-pox simultaneously ran their course in a child of 18 months old: the case proved fatal,

but the fatal termination does not appear to have been in any degree owing to the cow-pox. The other case is recorded in the Medical Gazette for June 13, 1835, by Mr. Grantham: it is one of great interest; and in this case I may remark that the cow-pox appeared to exert a decidedly beneficial influence over the variolous disease, the case terminating favourably.

REMARKABLE CASE

OF

PUNCTURED WOUND OF THE HEART,

FOLLOWED BY RECOVERY.

To the Editor of the Medical Gazette.

Sir,

I beg to offer you the following extraordinary and interesting case, as extracted from the Transactions of the Medical Society of Trinidad. It was read there last year by my friend Dr. Lynch O'Connor, a gentleman for whose accuracy, zeal, and medical ability, I can fully vouch, as, when in the army, he served along with me in the Windward Islands during the years 1815, 1816, and 1817, and was then distinguished by his zeal in the pursuit of professional knowledge. There are other papers from his pen, on yellow fever and similar subjects, but these, from their length, would, I conclude, prove unsuitable to the pages of the Medical Gazette.—I am, sir,

Your obedient servant,

Wm. Fergusson, M.D.

Inspector Gen. of Hospitals, H. P.

Windsor, Oct. 10, 1835.

Mr. J. H., a graduate of a British University, aged 30, was visited by me 20th April, 1821, under the following circumstances. He had lost his passage to Europe and that of his family (which was paid for by subscription), through his own imprudence. I found him in a sitting posture, perspiring profusely, with hurried respiration, and all the symptoms of acute inflammation of the heart or its membranes. I bled him in a full stream to sixty ounces, when deliquium coming on, he was able to lie down. The anxious countenance was nearly removed, and the voice, which before was scarcely audible, became more distinct. I remained with him for about forty minutes, when the previous symptoms returned with unusual violence; so much so, that I recommended his attendants to send for his friends, as I was apprehensive of immediate dissolution, and insisted on Dr. Williams being called in, as well as any other medical man he might wish. He obstinately opposed any further advice, in so earnest a manner, that I began to suspect he had some secret to conceal, and made so earnest an appeal to him regarding his orphan children, that he burst into tears, and stated that he had introduced a darning needle for the purpose of self-destruction, as he believed his object might thus be effected without detection, or disgrace to his profession and family; that he took half an ounce of laudanum previously, from the effect of which he slept eight hours, and after that the pain gradually increased to its present state.

Under these circumstances I sent for Dr. Williams, who said there was evidently carditis, but would not credit the introduction of the needle after he had carefully examined the part, which was situated between the fifth and sixth ribs. However, it was determined to make an incision down on the part, in conformity with the patient's desire, when the needle, three inches and a half in length, was found on a line with the external intercostal muscles. I attempted to secure it with the dressing forceps, but from the motion attending hurried respiration I could not succeed. Under these circumstances I sent for a watchmaker's pliers, with which I succeeded in extracting it. The moment the needle was extracted all the symptoms were gradually relieved, and in an hour after he merely complained of the incision. Purgative medicines were administered, and he was put upon low diet. In five days he was discharged from my care, and returned to Europe, where he arrived in perfect health, and lived for upwards of ten years.

(Signed) Jas. Lynch O'Connor, M.D.

ON FRACTURE OF THE PATELLA;

WITH A

DESCRIPTION OF AN INSTRUMENT PROPER FOR ITS TREATMENT.

To the Editor of the Medical Gazette.

SIR,

I SEND you the description of an instrument for treating fractures of the patella, by which the direct apposition of the two portions of bone can always be obtained, and the length of ligamentous union prevented, which is so often found to exist after this kind of injury, where the ordinary treatment is employed. If you can insert it in your valuable journal, I shall feel obliged.

I remain, sir,
Your obedient servant,
EDWARD F. LONSDALE.

8, Berners-Street,
Oct. 9, 1835.

The difficulty in treating fractures of the patella, by the ordinary method, depends upon the great degree of constriction it is necessary to make round the whole joint before a fixed point can be gained for the bandages to act upon, in order to bring the two portions of bone into contact; the consequence of which is, that the joint is unable to bear the pressure, and becomes swollen and painful, rendering it necessary to discontinue the bandages altogether, or else to slacken them so much, that all purchase on the bone is lost; and the muscles are then allowed to act upon the fractured portions, and produce separation between them, the upper portion being drawn from the lower.

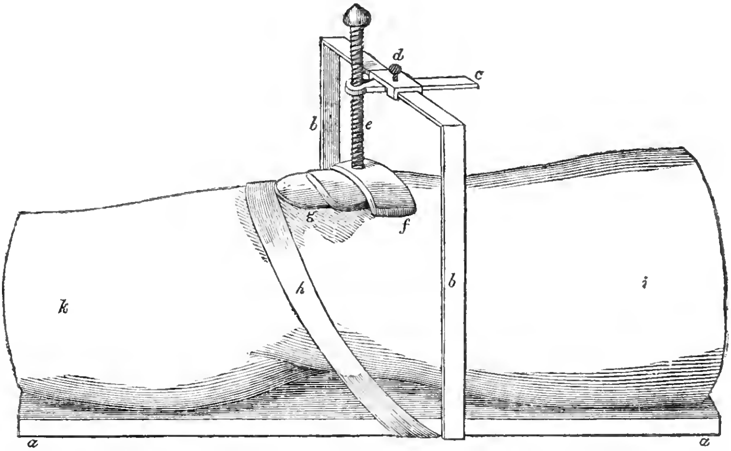
It often happens that swelling of the joint comes on immediately after the fracture, making it quite impracticable to employ the ordinary mode of treatment at an early period, and rendering it necessary to wait some time before any pressure can be made upon the part, or before any attempt can be made to approximate the two portions of bone; the consequence of which is, that much time is lost that is important for the production of bony union; and the muscles having contracted to a great extent, have become adapted to their new situation, and are little liable to yield afterwards when extension is made upon them, rendering it quite impossible to bring the upper portion of bone sufficiently down to the lower, to lie in contact. Ligamentous union is then a necessary consequence.

A case occurred lately at the Middlesex Hospital, in which the least attempt to approximate the two portions of bone by the ordinary treatment of placing the two lateral slips of bandage on either side of the patella, and confining them by a circular bandage and compress, placed above and below the bone, could not be borne, but caused so much pain and swelling of the joint, that it became necessary to discontinue the pressure at two or three different periods; the consequence of which was, that at the end of a month no approximation of the two portions of bone was effected, but a distance of nearly three inches remained between them.

It occurred to me some time ago, that an apparatus might be contrived by which the upper portion of bone could be brought down to the lower, by making pressure immediately above the bone only, and leaving the rest of the joint free, and unexposed to the constriction necessarily produced by the ordinary mode of treatment. The above case appeared to afford a good opportunity for trying the instrument that I had previously thought of, which I accordingly had made; and with the permission of Sir Charles Bell, under whose care the patient was, I applied it.

It consists of a thick wooden splint, which is placed behind the knee, long enough to pass half way up the thigh, and half way down the leg, and sufficiently wide to extend beyond the knee on either side. From a little above the centre of the splint, a bar of iron, about half an inch thick, is thrown across, so as to form a square or arch, which surrounds the joint, but does not come in contact with it; leaving a space of about three inches above the knee, and of about an inch on either side of it, so that the upper and lateral parts of the joint are free from all pressure. Through the central part of this square a flat bar slides backwards and forwards, and is perforated at its extremity to admit a vertical screw, to the lower end of which is attached a horizontal plate, wide enough to extend an inch on either side of the patella, and slightly hollowed anteriorly, to fit the upper convex margin of the bone. The object

of this part of the apparatus is to press immediately above the patella, and so fix the upper portion of bone, which, having been previously brought into contact with the lower, is kept there, and prevented being drawn up the limb by means of the sliding bar, which is fixed by a small screw made to turn upon it. The annexed drawing represents the instrument, and its application to the knee.



a a, The wooden splint applied to the back of the knee, extending half-way up the thigh and down the leg.
b b, The iron bar forming the square or arch round the joint.
c, The sliding bar fixed by the screw *d*.
e, The vertical screw which presses upon
f, The horizontal plate.
g, The patella fractured, illustrating the manner in which it is fixed by the plate *f*.
h, The strap fixing the lower portion of the bone.
i, The thigh.
k, The leg.

It is applied as follows:—The muscles attached to the patella are to be relaxed, as in the ordinary treatment, by extending the leg, and raising the heel and shoulders of the patient, so as to flex the hip-joint. The limb is then to be placed upon the back splint *a a*, which is done by passing the foot through the square formed by the bar *b b*, having previously elevated the vertical screw *e*. The upper portion of the patella is then to be drawn down close to the lower, and to be held there, care being taken that the integument is not pulled with it, so as to be included between the two portions of bone. The sliding bar, *c*, is now to be fixed at such a point, by means of the screw *d*, that the vertical screw *e*, when turned down, may cause the horizontal plate, *f*, to press, not upon the patella, but immediately above it, so that, if the pressure be sufficient, it will lie at a lower level than the bone, and prevent the upper portion being drawn up the limb. The lower portion requires but little fixing; it may be done by the strap *h*, with a small compress of lint placed between it and the bone. The splint itself is steadied by the weight of the limb, but an additional security may be given by attaching a bit of bandage to either side of the splint, and passing it under the sole of the foot. It will now be seen how the retraction of the upper portion of bone is prevented, by means of the horizontal plate; for if the sliding bar be firmly fixed, it cannot be pushed upwards without the whole apparatus goes with it, which is prevented by the bandage that passes under the sole of the foot, and by the weight of the limb pressing upon it.

The advantage of this mode of fixing the patella is, that the pressure employed is confined to so small a part of the joint, and is applied to the part that is best able to bear it, namely, upon the thick tendon formed by the extensor muscles of the thigh. The rest of the joint is left quite free and unexposed to pressure, and open for the application of local remedies; while in the ordinary treatment the whole joint is necessarily

confined and constricted to as great extent, by which any inflammation that may arise is increased, and the employment of local remedies, as leeches, &c. is prevented, without removing all the bandages, when the apposition of the two portions of bone must be disturbed, and an additional evil produced.

By the mode of treatment now recommended, the portions of bone, may be brought into contact immediately after the injury; for the swelling that takes place is mostly at the lateral and inferior parts of the joint, which parts are now free and unconfined.

The important point gained in this, as in other fractures, by the early approximation of the two portions of bone, is, that union can be effected at a much earlier period, and a more direct apposition of the fractured surfaces obtained, than can be the case where the two portions of bone are allowed to remain a long time before they are brought into contact, owing to the state of the joint being such as not to bear pressure generally upon it to the extent produced by the ordinary mode of treating fractures of the patella. This early approximation of the two portions of bone, then, can be obtained by the splint now recommended; for as the pressure does not confine the joint, any swelling that may arise will be free and unconstrained, and not require the removal of any part by which the apposition of the portions of bone will be disturbed.

The advantage of this splint was shewn in the above case, for it could be borne from its first application, although the joint would not bear the pressure produced by the ordinary treatment. The two portions of bone, however, could not be brought into direct contact; nor was this to be expected in this case, for the fracture had existed a month before the splint was applied; during which time the parts around the bone had become thickened, and no doubt ligamentous union already commenced, which would of course prevent the fractured surfaces being brought into immediate contact. The two portions of bone, however, were brought so near, that a distance of only half an inch existed between them, the distance at first being nearly three inches.

I have no doubt that when the splint can be applied at an early period, the portions of bone can be brought into direct contact, and so offer every chance for the production of bony union, the absence of which, in almost every case of fracture of the patella, renders this kind of injury of so serious a nature, by depriving the patient of the free use and strength of the limb, and causing lameness for life.

OBSERVATIONS ON ANIMAL TEMPERATURE,

Suggested by Dr. Williams's Paper.

By Dr. Wilson Philip.

To the Editor of the Medical Gazette.

Sir,

One of the most troublesome consequences of deviating from received opinions in our profession, and of all its consequences the most difficult to obviate, is, that those who reply, usually (especially if the question be a complicated one) reply only to part, not having before them all, that the author has said on the subject.

This may arise from two causes—either all that has been said being distributed among different publications, or the conclusions, in a great degree, depending on what has been ascertained on other parts of the subject, with which the part in question is intimately connected.

At one time I attempted, when such mistakes arose (which are very excusable, respecting the results of an investigation protracted for so many years), to set my opponent right, at least with respect to what I had advanced; but latterly I have allowed things to take their course, satisfied that the truth, whatever it may be, would sooner or later appear: and I the more readily arrived at this determination, because the majority of opponents on such occasions have never seriously considered the subject; an observation, however, which does not apply to the gentleman whose papers induce me to trouble you with this communication. He appears to me, from those papers, both capable of judging of such questions, and willing to take the trouble of carefully examining the data; two things which I have found seldom concur.

In the last communication of Dr. Williams, I find the following observations:—" Hence we must either ascribe to the functions of respiration and circulation the power of generating heat (although to small extent, unless supported by other functions), or, with those who attribute to the nervous energy a power almost omnipotent, assume that the heat generated after the removal of the brain is produced by the nervous organs still remaining in the body. This latter alternative is so entirely destitute of support, that it is unnecessary to discuss it. I will, however, remark of the only author who, to my knowledge, has advocated it, that he had a particular hypothesis involved in it. I allude to Dr. Wilson Philip, who considers animal heat to be a *secretion*, a *tertium quid*, resulting from the operation of the nervous energy, or electric fluid (for he holds them to be the same), on arterial blood."

It is premature to enter on any question of this kind till the point which must more or less influence all our opinions respecting the operations of the nervous influence is determined—namely, the nature of that influence.

I have, by the aid of many experiments, the most important of which have been repeated with the same results by eminent physiologists both of this country and the continent, endeavoured to determine this point; and in my Treatise on the Nature of Sleep and Death, lately republished from the Philosophical Transactions, and my Gulstonian lectures delivered this year, I have given a reference to these experiments; and from page 198 to page 213 of the former, and from page 42 to page 51 of the latter*, have collected together the arguments which appear to myself, and others well versed in such subjects, conclusive, respecting the identity of the nervous influence and voltaic electricity.

Let Dr. Williams examine these passages, in which the whole of the evidence is brought into a small space, and either admit the conclusion or distinctly point out the objectionable part of the evidence; and, the nature of the nervous influence being ascertained, we shall experience no difficulty in determining the points immediately connected with its functions. With regard to the particular position which he considers as wholly destitute of support, I believe he will find that there are more things to be considered than he is at present aware of. It would not, I believe, be difficult to prove, that the removal of the brain, in man altogether fatal to the *sensitive*, although it greatly impairs, does not destroy the *vital*, functions of the nervous system, the spinal marrow, the only other active part of that system, having, in its vital functions, no direct dependence on the brain.

Dr. Williams will find, if he refers to what is said of animal temperature in my Inquiry into the Laws of the Vital Functions (p. 150, third edition), that his term is too strong, when he says that I consider animal heat as a secretion. After referring to the whole of the facts I had stated respecting the subject, the inference is given in the following words:—" That the caloric which supports animal temperature is disengaged by the same means—namely, the action of the nervous power on the blood; by which the formation of the secreted fluids is effected, and consequently that it," that is, the particular action of the nervous power on the blood by which the caloric is disengaged, " is to be classed with the secreting processes."—And in a note, I observe that the intelligent reader will easily perceive how this passage must be modified, if the cause of heat is ever proved to be only a peculiar state of the particles of bodies.

If we employ the term caloric, and regard the cause of heat to be a distinct substance, it follows, of course, that nothing else can be meant in the passage just quoted than that its evolution from the blood is the effect of chemical changes produced in that fluid by the action of the nervous power, the immediate cause, as appears from direct experiment, of the formation of secreted fluids.

I am, sir,
Your obedient servant,
A. P. W. Philip.

Cavendish-Square, Oct. 14, 1835.

* The passage here referred to will also be found in the Medical Gazette, in which the lectures were first published. See Medical Gazette for May 30, 1835, pages 297, 298, 299, and 300.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

A Popular Treatise on Diet and Regimen; intended as a Text Book for the Invalid and the Dyspeptic. By W. H. ROBERTSON, M.D.

Of suicide Lord Byron somewhere says, "Some men judge so justly of themselves, as to anticipate the sentence of mankind." Our author, prescient of his doom, makes a sort of prefatory atonement, and *dies by his own pen*. However, as the law's fiat has a sanction that is always withheld from self-destruction, it shall be shown by the best of all witnesses—the author and his book (which last, containing *only* 252 pages, he modestly calls a *brochure*)—that, had the sacrificial knife been wielded by our hands, the critical fingers would not have been imbued in innocent blood. Had his literary life been prolonged, the first article in the impeachment would have been for impertinence,—videlicet:

"This book has been written partly for the convenience of my professional brethren, to save them much trouble and time; in fact, to put their patients in possession of general principles, without attempting to interfere with the application of those principles to individual cases of serious disease."

Let us hope he hath no professional brother, who would to a patient,—having a love of physic and a conceit that he could in any way minister to his own medical or dietetic wants,—present his own prescription with one hand, and with the other this "popular treatise," saying—

"Quod si tantus amor menti, si tanta cupido est,
—— et insano juvat indulgere labori
Accipe quæ peragenda prius."

Now come we to a pleasant lamentation over the excellencies of the book—

"The present *brochure* has suffered much from compression, from being confined as to space, and the consequence is the omission of much that is interesting on these subjects, and the superficial mention of much that deserves, and indeed requires, to be discussed at length, and entered into deeply."

Then follows great disinterestedness—

"I have been anxious to give the public a work so small, that no one should be frightened by its size; so cheap, that no one should be prevented from purchasing it by its price, having sacrificed much to gain these ends."

The whole winding up with a powerful recommendation of the style, which it were unjust to give in other words than his own:—

"This work, however, has other faults besides those that I have mentioned. The style is frequently faulty; the putting together of the fragments is, I confess, clumsily managed: but it is my misfortune to be one of those who cannot submit to the irksome task of thinking of the words in which the ideas are clothed, or of correcting, remodelling, or altering their dress. Let me anticipate the critic's censure, by the following quotation from Burton's Anatomy of Melancholy.

"'And for those other faults of barbarism, Dorick dialect, extemporanean style, tautologies, apish imitation, a rhapsody of rags gathered together from several dunghils, excrements of authors, toyes and fopperies confusedly tumbled out, without art, invention, judgement, wit, learning—harsh, raw, rude, phantastical, absurd, insolent, indiscreet, ill-composed, indigested, vain, scurrile, idle, dull, and dry; I confess all ('tis partly affected); thou canst not thinke worse of me than I do of myself.

"W. H. R."

The first chapter opens with two mottos. The first a very trite one from Martial; the other selected from a more modern author, commencing with, "Can I have my ailments removed without abridging my *appetites?*"—in which, if we substitute indulgences for "appetites," we shall find tolerably good sense.

After admitting the justice of the author's exceptions to himself, we have little to discommend, more than the utter superfluousness of such a production—it is supererogatory. It wants the science and vivacity of Dr. Paris's work on this subject, and vainly emulates the shrewd sprightliness of the "Peptic Precepts:" a bad imitation of both, it will supersede neither. Yet if the price be low, as the preface boasts, it is certainly not calculated to do harm.

The Appendix is amusing, inasmuch it professes to illustrate the doctrines of the book by "*fictitious cases!*"

Now, we have all heard of postulates in mathematics, and hypotheses in argument; but "fictitious cases" for the proof and elucidation of a practical art,

when the author confesses "it would have been much easier to have given real cases," are quite another thing. As the practice, however, is not without precedent, so we fear it will not lack imitators.

A New Practical Formulary of Hospitals of England, Scotland, Ireland, France, Germany, Italy, &c. &c. of MM. Magendie, Lugol, Dupuytren, Alibert, &c. Translated from the French of MM. Milne Edwards *and* Vavasseur, *and considerably augmented, by* M. Ryan, M.D.

The title of this book fully describes it; it is a sort of polyglot pharmacopœia, containing a good portion of useful matter, but mixed with a great deal more that will find but little favour at the hands of sagacious English practitioners. Occasions do present themselves when multiform prescriptions of incompatible substances appear to possess some advantage over simpler and more scientific combinations; but this being admitted, constitutes no reason for a general departure from prescribing upon principles so intelligible, that the physician shall always have a satisfactory answer to the medical Pyrrhonist's—*cui bono?*

Great number and variety of prescriptions infer corresponding faith in the prescriber; our confidence in whom would be nearly in the inverse ratio of the extent and diversity of his *materia medica*. It is certain that the number of medicines which admit of no substitute is exceedingly small: *e. g.* arsenic, antimony, mercury, acids, alkalis, opium and cinchona, and a few others. A great extension of this catalogue will rather embarrass than benefit patient, pupil, and practitioner.

Looking through this production, with a view of seeing what the translator did for it in the way of notes, or in what respect it has been "considerably augmented," we happened to alight on a section concerning *Aphrodisiacs*. We read it with disgust, and the more so as we found it was gratuitously introduced by Dr. Ryan. The feeling with which we perused it we can only compare to that excited in Gulliver by the filth and lechery of the Yahoos. He who could take an interest in such a subject would be well employed in assisting the philosopher who was busied with a certain extractive process in the flying island. To be more explicit in our allusions to these matters would be to pander to a taste, the existence of which we discredit, except in a very few instances, among the members of our profession.

MEDICAL GAZETTE.

Saturday, October 17, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

Cicero.

LACHRYMÆ TOOKIANÆ;

OR, A LAMENT FOR THE LOSS OF A CHARTER.

Poor Mr. Tooke! We never thought him so very simple a man as he has just shown himself. The late Duke of Saxe Gotha used to be trotted up and down a room, and then turned round, for the amusement of his company; but when he died, it was found that he had a bony tumor within his skull. Mr. Tooke, doubtless, has a crotchet of his own in his head, for he lets himself be spun like a tee-totum: or worse,—he suffers himself to be sent about like a common hawker, crying a sort of "last speech and dying words." At the bidding of his "very good masters" (the *Council* and *Professors* so called), he distributes through town a statement to inform the public that the joint-stock company to which he belongs, and in which he holds we know not how many shares, has been vilely treated; that *the* Charter by which he and his brother shareholders hoped to make a snug thing of the "University," has been basely refused; and that nothing more remains—nothing more is offered them—than a common part in the lot with the other medical schools.

There is, in short, to be no *dubbing*, after all, in Gower-Street.

This is a disappointment, assuredly, which the speculators on the price of stock cannot be expected to bear with patience. " It never," says Mr. Tooke, in the lachrymose and ludicrous document alluded to,—" it never entered into the contemplation of its friends that an expense of nearly 700*l*. should have been incurred to procure *a barren collegiate charter*, not worth the parchment on which it should be engrossed." We dare say it did not: 700*l*. is no inconsiderable sum to be squandered in idle litigation, more especially when funds have every day to be raised so ingeniously by the speculating parties in question.

But let us go through this " last speech" of Mr. Tooke *seriatim*, and in a manner befitting the occasion; for it is a solemn affair, bearing for its closing device the emphatic phrase " *Animam liberavi meam*,"—which we dare say means, that by this time the unhappy author has given up the ghost.

The opening is lawyer-like enough, containing the necessary quantity of sophistry, in the shape of the *suppressio veri*, and begging the question.

" The origin of this University in 1825, its opening in 1828, and its steady progress since in strict adherence to the *liberal* principles on which it was founded, are *too well known* to require illustration. A freehold estate of eight acres, on which is erected one of the most classical and ornamental buildings of the metropolis, and comprising within its site a convenient and well-conducted public hospital, constitutes an entire academical endowment, adequate to all the purposes of education in every department of liberal and professional knowledge."

The history and progress of the Gower-street school, no doubt, *are* " too well known." Its total failure as a school of arts—the successive resignation of all the respectable professors, (with but few exceptions) who originally belonged to it—its systematic puffing and pretension—and its monopolizing spirit,—are certainly too well known to need dwelling upon. But the *whole* truth, were it to be spoken, would require Mr. T. to say a little more: in alluding to the freehold estate, the valetudinarium, and the *most classical* nature of the building, he might have recollected that the first two are mortgaged, and the last all shell, emblematic of the hollowness of the whole establishment.

After this comes the piteous and " most lamentable comedy" of the grievous disappointment of the speculators: it is traced up from the "encouragement" held out by Lord Grey and his government in 1831 (regarding which *encouragement*, by the way, we rather suspect " the wish was father to the thought"), to the division of last session, on Mr. Tooke's motion for an address to the King; when as the honourable member boasts, it was carried by a majority of 110. But who does not know the history of that division, and the factious manœuvring by which the result was effected? Who can be forgetful of the weight of the radical influence on the occasion, and the foregone determination of embarrassing the ministry of Sir Robert Peel?

We take leave to pretermit the details on this subject with which Mr. Tooke favours us: they contain nothing new for our readers, though the *temperate* tone in which the " opposing petitions from Oxford and Cambridge" are mentioned, as well as those other memorials " from some medical societies and schools," might amuse, if we had only space to devote to it worthy of its merit. We might also notice the gentle whine in which it is told that " the Council were *induced to submit to a restriction* against granting medical

degrees," and the ridiculous blundering with which the complainant talks of rights and claims,—as, where he says that the Council and Professors (save the mark!) were not prepared to relinquish the *right* to confer degrees of the same description as those given by the English Universities—and that the latter bodies "had no pretence for an exclusive *claim*," &c.: but the paper is full of this sort of absurd talk—and a specimen such as we have given may be all that is necessary.

Then follows his Majesty's "gracious" answer to the House of Commons' address. Every body knows what that answer implied, and how nearly it resembled every other civil response given to addresses, however unpalatable and not to be complied with. But Mr. Tooke puts a meaning of his own upon it, and fancies all the world thinks as he does. "The general impression," says the writer, "consequent on this answer was, that the Charter, with very slight modifications, would be immediately issued by the then government."

Was it so indeed? Is this stupid credulity on the part of Mr. Tooke, or is it an attempt to gull his reader? We rather fear the latter: for the answer, in all conscience, was as plain as words could express it—simply that the Privy Council should be pressed for their report, in order that his Majesty might act accordingly. So far from misleading any rational person to suppose that it contained a promise of a charter, every infant must perceive that it was altogether a thing of civility—in fact, a polite put-off.

The present ministers are next taken to task for presuming to hoax Mr. Tooke. For some months, he tells us, they managed to amuse him; but at last, on the 17th of July, the Attorney-General took the liberty of speaking to him any thing but words of comfort. The first law officer of the crown told him, he says, that *two* charters were prepared (this must have raised high expectations in the listener, but, alas! only to be blasted by what followed)—one for "the University," reducing its style and title to that of a "College" (how dreadful!) and thereby precluding it from the privilege of granting degrees,—the other, constituting a Metropolitan University, which should examine for and confer degrees on students proceeding from the several recognized schools.

This seems to have been a thunder-clap to poor Mr. Tooke: but he rallied a little, and presently charged his small artillery to return the compliment; we rather surmise, however, that on consulting his friends, "the Council and Professors," he was recommended to reserve his fire till the opening of the session. It would not do to let the report be heard; much less to have it repeated with troublesome echoes that the chance of a charter was gone for ever: the more *that* untoward piece of intelligence could be bottled and smothered up the better, till after the opening of the session.

Some little change, by the by, seems to have come over the dream of Mr. Tooke since the summer. We observe he takes great pains in his present statement to make the world believe that the Privy Council were on the whole favourable to the proposition of a charter, and that had they not prematurely dissolved, their report would have been all that could be wished. Mr. T. is indignant with the public papers which pretended to announce the feelings of the Privy Council on the subject, and their decision against the measure by a majority: he says there is no truth in this. We fancy, however, it would not be difficult to bring to Mr. Tooke's mind the fact of his having himself been mainly instrumental in propagating such a story. Does he forget that in May

last he made no scruple of speaking freely of the *decision* of the Privy Council against the "University," and that he even went into minute detail to many listeners, naming those Lords who had unexpectedly absented themselves, and those who voted against the measure? The exact numbers were not omitted. But how conveniently short are the memories of some people! A few short months have wiped all the circumstances clean out of the Tookian tablets.

The board—this proposed Metropolitan University board—is the next rock of offence stumbled against in the statement. And it is amusing to observe with what perfect *naïveté* our poor gentleman endeavours to show that the Gower-Street establishment ought to be left free and independent of any such board: or that if it must submit, at least that the Council and Professors ought to be entrusted with the formation of it. "If the University of London," says Mr. T., "should obtain the power of conferring degrees as a separate body, there can be no doubt that *in no long time it would raise up a body of graduates, to whom its examinations might safely be entrusted.*" How very accommodating! No doubt it would be highly satisfactory to the other schools of the metropolis, if they objected to sending their pupils for degrees to the teachers in Gower Street, still to have a *dernier resort:* the said teachers would obligingly raise up a senate "in no long time,"—a disinterested uninfluenced senate, composed of the first fruits of the system—graduates of the Gower-street joint-stock self-styled University! Thus "the supposed difficulty," according to the statement, "would soon be obviated."

Yet will the reader believe that, in the very next paragraph, the "University" is said to desire "*no exclusive privilege?*" Such is the fact. Nay, again, in a subsequent passage it is stated, *totidem verbis*, that were *it* merged, as it would [we trust, *will*] be by the ministerial measure, with other institutions, "its energies would be repressed, its individuality extinguished, its integrity of purpose impaired," &c.; for which reason *it* spurns the proposed central board, and can only be satisfied by being itself, *par excellence*, allowed to confer degrees. Yet this immediately follows the assertion that "the University of London solicits no exclusive privileges"! What have the Council and Professors been about, that they should suffer their unhappy "solicitor" to make such a confounded exhibition of himself?

In a postscript, evidently of recent date, we find the writer in a high delirium — the precursor, no doubt, of the regular expiration which he makes of it in the end. He has just discovered that the Central University Examining Board is to be composed of Commissioners named by the King, and that candidates for degrees are to be admissible to it from all parts of the United Kingdom, and from every recognised seminary of education, whether chartered or unincorporated. This is more than he can bear: he becomes furious, and abuses Ministers fearfully; he denounces the Board that is to be, sneers sarcastically at "the erudite, the Lords of the Treasury, and the Secretaries of State," and "that very learned body the House of Commons,"—totally forgetful of the high terms in which he mentioned the said House a little before, for lending him the assistance of a packed majority. At last, though, he bethinks him of an expedient: a happy thought strikes him: he suggests an antidote. It is this: to take advantage, and make the most possible, of the King's answer. "His Majesty having, in his most gracious answer, recognised by name the University of London" ["so called" being evidently omitted by mistake], is it not

proper that the proprietors should avail themselves of "this *sanction*," and "confer all manner of degrees, except in theology and medicine?" Ought not such a power, he asks, to be exercised in the ensuing session "in proud and fearless competition with any existing institution?"

Truly, Mr. Tooke, you have "liberated your soul" in a hopeful mood. You would deserve to be canonized for the integrity and wisdom of your dying suggestion. The plan proposed is quite worthy of the party who suggested, not long ago, at a meeting of the proprietors, to lay an embargo on the shares, and to confiscate the property vested in the establishment, in order to meet the objection of the "University" being a joint-stock concern.

It now only remains to be seen what the "University" will do. Will they really venture to act on the advice of their worthy solicitor? or has that suggestion of his been only thrown out as a feeler, like the confiscation project? It is truly pitiful to observe the shifts of the whole set: nothing seems too mean—nothing too tricky, for their adoption, so as it only opens the prospect of saving them from ultimate bankruptcy. We should not be at all surprised if they tried the plan of their worthy solicitor: nor shall we say that they have taken us unawares if, ere long, we see them embarked in a brisk traffic of degrees,—in humble imitation of the *flourishing* "College of Medicine, Lancaster Place, Strand."

Since the above was written, we perceive with much pleasure that Professor Key, in an opening lecture, has expressed himself in terms of satisfaction regarding the new charter. Only let his colleagues speak out in like manner, and our hostility shall no longer subsist.

"FAMA CLAMOSA."

CASE IN THE SCOTTISH COURTS INVOLVING THE QUESTION OF *VIABILITY*.

To the Editor of the Medical Gazette.

SIR,

I BEG to direct the attention of your readers to the following report of proceedings in one of the Scottish Church Courts. It will interest them as professional men, and may induce some of them to favour us with the results of their experience on the point at issue.

The child in this case is stated not to have been three pounds in weight: now last summer I saw one, prematurely born (certainly before seven months), which at birth weighed only two pounds and a quarter; it was alive when I saw it, and lived twelve days. But the important question, and on which I seek information, is, at how early a period of premature birth has the life of a child been preserved?

On Wednesday there was a *pro re nata* meeting of the Presbytery of Kirkaldy, relative to Mr. Jardine, of Kinghorn, whose lady has given birth to a living child within six calendar months of his marriage. Mr. Jardine was married on the 3d March, and Mrs. Jardine, on the 24th August, was delivered of a very weak child—not three pounds in weight—but which, with great care, has hitherto been kept alive. About three weeks since, after a meeting of Presbytery, held on the subject of shutting up a road which led to the kirk and manse of Kinghorn, Mr. Jardine informed the Presbytery of Mrs. Jardine's premature delivery; and as there were reports in circulation injurious to his character and usefulness, threw himself on the Presbytery, and called on them to make the fullest investigation, solemnly declaring at the same time his innocence of every thing criminal. The Presbytery agreed to request Dr. Hamilton, Professor of Midwifery in the University of Edinburgh, to come to Kinghorn to investigate and report; but if not convenient for him to come, a similar application was to be made to Dr. Thatcher. Dr. Hamilton could not come, but wrote two letters, stating that his own experience was opposed to the probability of a child, born in the sixth month, surviving; referring, however, to two cases where children had lived under similar circumstances of premature birth to that of Mr. Jardine's child. One of these occurred in 1710, when the wife of a clergyman in the Presbytery of Wigton was delivered of a living

child within five lunar months after marriage; and the celebrated Dr. Pitcairn, of Edinburgh, and other two eminent practitioners, gave it as their opinion that that child had been procreated after the marriage of its parents. The other case occurred in Paisley in 1815, when a married woman, who previously had children, gave birth to a living child nineteen weeks after conception, and it lived a year and a half. Dr. Thatcher was then written to, and he came to Kinghorn and examined the child; as also Dr. Reid, of Kirkaldy, who was accoucheur to Mrs. Jardine; the sick nurse; and the other persons present at the birth; but the certificate he gave, which was laid before the Presbytery on Tuesday week, not being so explicit as some members wished, he was again written to, when he transmitted a certificate, of which the following is the substance:—

"I hereby certify, in connexion with my former certificate and note appended, that I consider it quite possible that the child of the Rev. Mr. Jardine was begotten on or after the 3d day of March last, born on the 24th day of August subsequently, and reared in the premature state described; and I consider the *fama* on this circumstance, against the minister of Kinghorn, as utterly groundless."

On Wednesday this communication was laid before the Presbytery, when the majority of the members expressed themselves perfectly satisfied; and Mr. Guild, of Auchtertool, submitted a motion to the effect, that from the certificates of Dr. Thatcher, it appeared there was no evidence to criminate Mr. Jardine, and that the *fama* against him was unfounded. A good deal of conversation followed, in the course of which a petition, signed by about thirty of the parishioners, was given in, praying that the Presbytery would order a Presbyterial visitation of the parish, "before coming to any decision whatever in reference to the subject of the birth of the child." This petition was received, and ordered to lie on the table. The discussion was here renewed with considerable keenness, Mr. Jardine deprecating the Presbytery being driven from their purpose of coming to a decision by the side-wind of this petition, stating, that if the petitioners were prepared to libel him, he would meet them most readily. The Presbytery, however, was bound to come to a finding on the evidence before it, which would not preclude the parishioners taking any steps they might hereafter consider proper. Mr. Murray, of Dysart, Mr. Cunninghame, of Kinglassie, and others, supported the Presbytery coming to a finding similar to that proposed by Mr. Guild. Mr. Christie, of Durie, coincided in opinion that the medical certificates completely exculpated Mr. Jardine; but thought the petition of the parishioners ought to be attended to, and suggested that the Presbytery be adjourned. Mr. Bell, of Kennoway, concurred in the suggestion of Mr. Christie. Mr. Murray, of Abbotshall, and Mr. Thomson, of Dysart, contended it was for the interest of Mr. Jardine that the Presbyterial visitation should be ordered, the more especially that the decision of a *pro re nata* meeting might be cancelled by an ordinary meeting. Mr. Murray, of Abbotshall, argued that the Presbytery ought to have called Dr. Reid before it, and examined him on oath. To this it was replied by Mr. Brewster, that it could hardly be expected that any member of Presbytery would conduct such an examination: hence Dr. Thatcher had been applied to to take evidence, and his report was now before them. Mr. Seiveright, of Markinch, in reference to some remarks made at a former meeting relative to Dr. Reid, read a letter from that gentleman, in which he denied having used certain expressions generally attributed to him. When examined by Dr. Thatcher, whom he had never before met, he (Dr. Reid) considered himself in the character of a witness. Dr. Martin, in a lengthened and remarkably logical speech, delivered with much feeling, contended that, besides the medical certificates, every presumption was in favour of the innocence of Mr. and Mrs. Jardine. Their previous character was free from all suspicion, and there had been nothing like concealment practised. Their intended marriage was approved of by their respective friends months previous to its celebration, and there was nothing to prevent its taking place. When the child was born there was no preparation for it—not a single article of clothing—the parties were all taken by surprise, and no one ever expected the infant to survive. After some further conversation, the motion of Mr. Guild, altered to the following effect, was unanimously adopted:—

"The Presbytery, having deliberately considered the evidence before them, as afforded by the certificates and letters of Dr. Thatcher, relative to the case of Mr. Jardine, declare that there is no ground to charge him with the criminality alleged against him."

The Presbytery agreed to delay consideration of the petition till next ordinary meeting. Against these proceedings Mr. Barclay, on the part of the petitioners, protested, and appealed to the Synod*.

GENERAL LYING-IN HOSPITAL.

MIDWIFERY REPORTS.

By Edward Rigby, M.D. F.L.S. &c.

[Continued from page 32.]

Case complicated with Mental Depression.

The next case is, indeed, a melancholy one. The patient had been born to better and brighter hopes. The favourite of a respectable family, well educated, and possessed of considerable personal attractions, she had been seduced by a licentious foreigner under promise of marriage, and then deserted. During her pregnancy she had lost her mother under peculiarly distressing circumstances. She had been seized with a fit shortly after being made aware of her daughter's ruin, and being near the fire at the moment, had fallen against the stove, and been so severely burnt as not to survive long. This had tended not a little to increase her state of mental suffering; she considered herself to have been the cause of her mother's death, and from that time nothing appeared to rouse her from the melancholy subject which occupied her thoughts. She made no complaint; and to any inquiries after her health almost always returned a favourable answer. Her nights were passed quietly, but she seldom appeared to sleep. For the particulars of this long and interesting case I am indebted to my friend, Mr. Bell.

"Dec. 21st, 1834.—M. H., æt. 22 (single); delivered of a boy; first child; second position; labour natural, and very quick. She was in the hospital a short time before her delivery, during which there was a remarkable depression of her spirits; her face and lips were always pale, and this paleness did not leave her even when straining during labour. About two hours after her delivery she complained of giddiness; and thinking it might arise from fatigue, the nurse gave her some tea; immediately upon taking which she was seized with a profuse discharge of serous fluid from the vagina, which at first flowed slowly, but afterwards came in gushes, accompanied with great faintness, ringing in the ears, and sinking of the pulse. The discharge was so profuse as to completely soak the sheet which was doubled round her, and several folds of the bedding beneath. On examining the uterus it was found enlarged, extending to the umbilicus, and soft, but there were no clots felt on introducing the hand into the vagina. She had another sheet bound tightly round her, and the following draught was given:

> Sp. Ammon. Arom. ♏x.; Ætheris Sulph. ʒss.; Aq. Menth. Pip. ℥j. M.

after taking which the faintness left her, and the pulse rose.

22d.—Feels better, and had only one return of the giddiness during the night; she has slight tenderness of the abdomen, and constant pain in her back; she has not passed water since her delivery, and the bladder is felt much distended above the pubes. Lochia profuse, and some small clots have come away this morning. The catheter was introduced, and a large quantity of high-coloured urine was drawn off, which relieved the pain of abdomen; pulse frequent and feeble; tongue white, and very tremulous.

27th.—Says she is quite comfortable, and has had no pain in her back for several days. Lochia regular, but unnatural in appearance since the second day after her delivery. Bowels have been kept regular by castor oil; but as she expressed great dislike to it, she had to-day four grains of comp. ext. of colocynth, and the same of ext. hyoscyami. Spirits much depressed; face very pale. Appetite good, and she has meat; notwithstanding which her milk has diminished in quantity.

28th.—In the morning appeared much as she was yesterday; had a grain and a half of quinine at noon. In the evening she became slightly incoherent, and when she was spoken to started as from a stupor, but answered quite collectedly. Dr. Rigby saw her, and ordered

> Camphoræ, Ext. Hyosc. aa. gr. iv., and to be repeated in three hours.

She has slept indifferently for some nights.

29th, 8 A.M.—Makes no complaint, and says she feels quite comfortable. Bowels opened three times since last night; pulse 144, very feeble; tongue white and tremulous.

> ℞ Liq. Opii sed. ♏vj.; Mist. Camph. ʒss. statim.

Noon. — The bowels have not been opened.

> To have a grain and a half of quinine. Arrow root and port wine for food.

Has been occasionally incoherent during the forenoon. Dr. Rigby saw her soon after.

> ℞ Opii duri, gr. j.; Camphoræ, gr. iij. M. omni horâ usque ad somnum. Let her have emulsion of egg and brandy.

After taking three of the above pills she fell asleep, but was very restless.

Pulse 144, very feeble; subsultus tendinum.

9 P.M.—Has just waked suddenly and leaped out of bed, and said she wished to dress herself, as it was time she was up; she seemed to be labouring under great nervous irritation, and spoke hurriedly, though collectedly. She returned quietly to bed.

Continue the opium and camphor, and to have a draught containing one grain of quinine, ten drops of diluted sulphuric acid, in a little cold water, at 3 in the morning.

30th, 9 A.M.—Has passed a quiet night; tongue very dry; bowels opened once; pulse 144, rather fuller.

Repeat the quinine and sulphuric acid immediately, and every two hours.

Half-past 3 P.M.—Complains of pain in her left side when she breathes. Tongue moister; pulse 100, intermitting, and very feble.

To have the side rubbed with anodyne liniment; the quinine to be continued; and to have beef-tea frequently.

5 P.M.—Much the same as at last visit. Dr. Rigby saw her, and ordered the opium and camphor to be given at 6, and the quinine at 8.

Omit the beef-tea, and let her have calf's-foot jelly instead.

9 P.M.—Pulse again up to 144, fuller, and more regular; tongue dry, and very tremulous.

Half-past 11.—Has had some sleep, but moaned very much during it. When spoken to she requires some time to collect herself to answer. Dr. Rigby saw her.

℞ Ext. Hyosc., Ext. Gentianæ, aa. gr. iv.; Quinini Sulph. gr. ij. M. and divide in pil. ij. to be taken at 2 in the morning. Continue the beef-tea.

31st, 8 A.M.—Slept a good deal during the night, but moaned and seemed much distressed. Is much weaker, and has great difficulty in speaking, or in opening her mouth to shew her tongue, which is very dry. Has taken very little of the beef-tea; stomach slightly distended.

10 A.M.—Not having passed water since last night, the catheter was introduced, and brought away nearly two pints of urine with much relief.

℞ Ext. Gentianæ, Camphoræ, aa. gr. vj. Quinini Sulph. gr. iij. M. ft. pil. iv., two every two hours. Continue the beef-tea. The catheter to remain in, and the water to be drawn off every two hours.

Jan. 1st.—The powers of life continued to sink gradually, and she died without any suffering at 10 this morning.

REMARKS. — There are several remarkable facts about this interesting case, which are well worthy of notice. The great and overpowering depression of mind must be looked upon as the main cause of her having sunk thus; it was a state of profound melancholy, which was beyond the passionate demonstrations of common sorrow, and which annihilated every other thought and feeling. To the great depression which the physical powers suffered from this state of mind must we attribute the sudden and very remarkable discharge of serous fluid from the vagina, which took place after labour. Serous discharge from the vagina may occur under very different states, and from equally different causes. In the present case it appeared to result from insufficient contraction of the uterus, allowing the watery portion of the blood to escape from the mouths of the vessels which open upon the lining membrane of its cavity. This affection has been lately noticed by Dr. Ashwell, in the Medical Gazette, and also by Mr. Bury; but with the exception of Dr. Ashwell's last case, it appears to have been of a different character.

The delirium and other symptoms which appeared on the 28th, were as much the consequence of sleeplessness as of debility. She had passed her nights so quietly, that to a person merely passing through the ward she appeared asleep, although, on going up to her bed, she was always found awake. It was to calm the cerebral excitement and produce sleep that I prescribed the henbane and camphor. The next day passed much in the same manner; she said she felt quite comfortable; but the fact was, she had not slept to any extent, and a return of incoherence justified the active doses of opium which I then exhibited. It now, in short, became a struggle (and a fruitless one) between the prostration into which she was gradually sinking, and the efforts of her attendants to rouse the failing powers of life. My own conviction is, that even if the powers of her constitution had been able to withstand the depression under which she laboured, the mind would not, and that mental aberration would have been the result.

[To be continued.]

VAGITUS UTERINUS.

M. DUBROCA, of Barsac, has communicated a remarkable instance of this kind to the *Bulletin Méd de Bordeaux*. He says that in 1827 a midwife called upon him,

and mentioned, with evident incredulity of her own story, that she had just heard an infant cry in the womb of its mother. M. Dubroca went immediately to see the woman. She was a person in good health, had already given birth to two children, and was now in the eighth month of her pregnancy. The crying had begun during the preceding night, and had continued since, with intervals only of a few minutes cessation. The noise was that of a new-born infant, but not so loud; rather resembling the cry of a child shut up in a box. When the woman walked, the voice always seemed to proceed from the place where she was. After three days the phenomenon ceased altogether; but it was not till a month and a half afterwards that the child was born. It was a fine male child, which uttered cries at birth, exactly like those previously heard: it is still living. The poor woman (the mother) was greatly alarmed, and shed tears copiously. Somebody had frightened her by saying that she must be possessed with the devil, if she was not a witch or a ventriloquist. M. Dubroca was satisfied that she was no witch at least, and seems persuaded that she knew nothing of the nature of ventriloquism.

RADICAL CURE OF VARICOCELE.

Dr. Fricke, of Hamburgh, has cured three patients labouring under varicocele, by simply passing a needle and thread through the dilated veins, and allowing the thread to remain for twenty-four or forty-eight hours, according to the degree of reaction produced. He recommends the method as being as safe as it is simple.—*Gaz. Medicale.*

TURPENTINE IN SCIATICA.

Dr. Ducros, of Marseilles, gives an account of the great efficacy he found in spirit of turpentine administered in cases of sciatica. He employed it in the form of lavement; gradually increasing the quantity at successive injections, until it amounted to two or three ounces. He conceives it to have a specific effect.—*Gaz. des Hôpitaux.*

PUBLIC HEALTH IN PARIS.

A species of typhoid fever has prevailed epidemically in the metropolis during the last year, and still continues its insidious ravages. An alarming number of young men, students in law and medicine, have been cut off: and of the troops which have come in the course of the year from the provinces to Paris, above one-third have been lost.—*Revue Medicale Française.*

ECOLE DE MEDICINE.

The opening of the school is fixed for the 2d of September. M. Broussais is to deliver the introductory address, which it is expected will be a very different thing from that pronounced last year by M. Fouquier.—*Gaz. des Hôp.*

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE IV.

ON THE SECONDARY OR THERAPEUTICAL EFFECTS OF MEDICINES.

EXPERIENCE has demonstrated that diseased action may be modified by the exhibition of medicines, and the modifications which are thus produced have been denominated *secondary* effects, because they are subordinate to those already described under the name of physiological. As we take advantage of them in the treatment of diseases, they have been likewise called *therapeutical* effects; and there are certain terms in use which refer solely to them, such as—febrifuge, bechic, stomachic, antiseptic, antispasmodic, antiperiodic, deobstruent, antiscorbutic, anodyne, antiarthritic, antivenereal, antihysteric, lithontriptic, &c.

It were, however, much better if these terms had been altogether banished from the Materia Medica, since they convey little meaning. To say that a substance is febrifuge gives you no information as to its mode of operation; for bloodletting, emetics, purgatives, sudorifics, blisters, stimulants, sedatives, narcotics, mercurials, and tonics, have been successfully employed in fever, and deserve, therefore, to be termed febrifuge, notwithstanding that their action on the body is diversified, and in some cases completely opposite.

But these terms are objectionable on another ground; they are not always appropriate. You cannot say that sulphate of quinia acts as a febrifuge when fever is not present; nor that opium is an anodyne, when no pain exists. We ought rather to imitate the naturalist who draws his characters of animals and vegetables from those properties which are constant and invariable, and avoids employing all those which are temporary and accidental. If it be desirable (and no one can doubt but that it is so) to have some term expressive of the effects which certain agents produce on the body, let that term apply to those effects which are constant and universal; let all phrases of dubious meaning be avoided—phrases that can only be applicable in particular conditions of the body, and not always even then; for sulphate of quinia is not febrifuge in every fever, nor is opium anodyne in all painful affections.

Remedies are not uniform in their influence over diseases: at one time we find them beneficial; at another, the same agents are insignificant and useless, or even absolutely hurtful, apparently under similar circumstances. In a large proportion of diseases, if not in all, there exists a natural tendency in the constitution to the healthy state—a tendency which constitutes the *autocrateia* of Stahl, the *vis medicatrix naturæ* of Cullen. In those diseases usually termed malignant (cancer and fungus hæmatodes, for example), we have no evidence of the existence of such a restorative principle beyond their occasional stationary condition. Now in most cases our remedies facilitate the removal of diseases only by removing those circumstances that prevent the full operation of this tendency; a *cure*, consequently, is rather referrible to nature than to the efforts of the practitioner. Nay, when we see patients recover under the most opposite means of treatment, we can hardly refuse our assent to the observation of the late Sir Gilbert

Blane, that in many cases patients get well in spite of the means employed; and sometimes when the practitioner fancies he has made a great cure, we may fairly assume the patient to have had a happy escape.

It will readily be admitted that medicines frequently influence and modify the progress of disease; but their *modus operandi* is not so easily explained, in consequence of the little knowledge we possess of the nature of vital action. However, it is probable that every medicine acts either on the causes of diseases, or on the vital properties of the part affected, and on this belief we may construct the following table:—

Medicines may act	On the causes of diseases	directly *(specifica qualitativa)*	
		indirectly.	
	On the vital properties of the diseased parts	immediately	
		mediately by	mechanical relations,
			functional relations,
			sympathetic relations.

I. *Of the operation of medicines on the material causes of diseases.*—Under this head I include all those cases in which medicines remove known causes, or, to use the language of Dr. Pring, which act upon a direct principle of causation. We make two subdivisions; the first including those causes *directly* acted on, and the second those that are affected *indirectly*.

a. Those medicines which act *directly* on the causes of disease are denominated by Hufeland *specifica qualitativa;* they are the substances usually called *specifics*. We know, for example, that the tape worm (*tænia solium*) sometimes occasions serious symptoms; and that the oil of turpentine frequently relieves, by causing its destruction and expulsion. Now it is supposed that the oil acts as a poison to the worm. It has long been suspected that scabies is produced by an insect called the *acarus scabiei*, and that sulphur cures by destroying it. If this opinion be correct, we have here another instance of the direct operation of a medicine on a morbific cause. I may remark, however, that, although the existence of an insect has frequently been demonstrated, yet it is not determined whether we ought to regard it as the cause, the accompaniment, or the effect of the disease, and, therefore, we can speak but doubtfully as to the mode by which remedial means influence scabies.

Corrosive sublimate, and the salts of copper, taken into the stomach in large quantities, inflame this viscus. Now, albumen, or the white of eggs, decomposes them, and diminishes their activity. Hence the chemical antidotes, like the substances called specifics, act on the causes of diseases. It is much to be regretted that our list of specifics is so extremely limited. Foy, a French pharmacological author, admits a distinct class of medicines under this title; but he employs it in a far more extensive sense than is generally done. If, says he, the term specific be confined to those agents which invariably cure a disease, there are not any substances deserving this appellation; he therefore calls those medicines specifics which are better adapted than others to certain diseases.

In this sense he admits the following subdivisions of the class *specifica*.

1. *Specifics for syphilitic affections*, including the preparations of mercury and gold.

2. *Specifics for cutaneous diseases.*—These he divides into vegetable (namely, *fumaria*, *cichorea*, *rumex patientia*, and *arctium lappa*;) and those furnished by chemistry (namely, sulphur and its preparations, arsenicals, iodnret of mercury, and some preparations of phosphorus.)

3. *Specifics for periodic affections.*—Under this head are the principal vegetable tonics, as cinchona, willow, simaruba, and other barks, sulphate of quinia, salicine, &c.

4. *Specifics for scrofulous affections*, divided into (*a*), general means, as elevated places, healthy habitations, strengthening food, exposure to the sun, &c.; (*b*), vegetable substances, as hops, gentian, cinchona, &c.; (*c*), substances furnished by chemistry, as iodine and its preparations.

5. *Specifics for intestinal worms, or anthelmintics*, arranged under the heads of vegetable substances, as Corsican moss, male fern, wormseed, castor oil, &c.; agents furnished by chemistry and mineralogy, as tin, calomel, petroleum, &c.; and, lastly, animal substances, as white coralline.

This table is interesting as showing what agents have been celebrated in particular diseases, but the term specific is employed too loosely.

b. Substances which act indirectly on the material causes of diseases.—Suppose a gall stone to have escaped into the ductus choledocus; it may, in this situation, excite spasm and inflammation. Now it has sometimes happened that the stone has been dislodged by the mechanical influence of vomiting. If, therefore, vomiting had been caused by ipecacuanha, this medicine would have given relief through its indirect

action on the cause (the calculus) of the disease (spasm and inflammation). We can conceive, also, other cases in which the relief obtained is referrible to a similar mode of causation.

In some instances medicines indirectly remove the effects of a previous disease, which effects, by their reaction, maintain a secondary morbid state. For example, the bowels may be loaded with depraved secretion, the result of some previous disorder, but which has now subsided; and this secretion may excite a secondary morbid condition of the system. A purgative may relieve all these symptoms, by removing the cause or reagent.

II. I proceed to examine those cases in which we believe the beneficial effect of a medicine depends, not on its action on the cause or causes of the disease, but by its influence over the *vital properties* of the *diseased part*.

In a large majority of instances, the causes of disease are either not of a material nature, or are unknown. In all such cases we administer medicines with the view of producing certain changes in the actions of one or more parts of the system, and thereby of so altering the diseased action as to dispose it to terminate in health. Thus inflammation of the lungs frequently subsides under the employment of nauseating doses of tartarized antimony; and emetics will sometimes put a stop to the progress of hernia humoralis. In these instances the remedies appear to have an indirect relation only to the disease.

The following arguments have been advanced by Barbier, to prove that the therapeutic effects of medicines are, in most cases, consequences of the physiological changes they have produced in the system.

1. A medicine seldom produces an amendment in a disease without primarily giving rise to an organic operation in the body affected.

2. When from age, bad preparation, or any other cause, a medicine has lost its power of acting on the living organs, or when from habit or idiosyncrasy the organs are insensible to its action, it becomes useless as a therapeutic agent; it no longer possesses a power of alleviating or curing diseases. So that those causes which annul the active force of medicines destroy also the curative powers.

3. Those medicines which produce the most violent physiological effects are the most powerful therapeutic agents; for example, tartar emetic, opium, bark, &c.

4. A specific curative power in medicines cannot be demonstrated. To admit that medicines act on the causes of disease would be to assume that these causes are of a material nature—an assumption which, in nine cases out of ten, is unwarrantable.

5. Sometimes medicines which are regarded as specifics in certain diseases exasperate, instead of removing the symptoms. Frequently we find febrifuges increasing the intensity of a fever, tonics augmenting the debility of the system, and antispasmodics adding to the violence of the nervous symptoms. Now this could not be the case if these agents possessed the powers that their names indicate.

6. In order to produce beneficial effects, medicines must be exhibited at the proper time. Cinchona bark, for example, may at one stage of an intermittent put a stop to the paroxysm, at another increase its intensity.

7. Various external circumstances have occasionally been useful in diseases, and which cannot possess any specific curative power. Thus sudden fright has sometimes prevented the paroxysm of an intermittent fever; removal to a warm climate frequently causes all the symptoms of pulmonary diseases to disappear.

Medicines which act on the vital properties of a diseased part may do so in one of two ways, either immediately, that is, by local contact, or mediately, that is, by an operation on some part having a relation with that diseased.

a. Medicines operating immediately on the vital properties of the diseased part.—Under this head we include those agents called topical, as unguents or lotions in cutaneous diseases, ulcers, &c.; gargles in affections of the mouth and throat; collyria in ophthalmic diseases; and injections into the vagina and uterus in affections of these organs. In all such cases we can explain the therapeutic effect in no other way than by assuming that the medicine sets up a new kind of action in the part affected, by which the previous morbid action is superseded, and that the new action thus set up subsequently subsides. Sometimes it may be suspected that the influence which certain agents exercise in diseases of remote organs, arises from the medicinal particles being absorbed, and, through the medium of the circulation, carried to the parts affected. Thus the beneficial influence which the turpentines occasionally exert on mucous membranes (as in gleet and leucorrhœa) may perhaps be owing to a topical influence of this kind; as also strychnia in affections of the spinal marrow.

b. Medicines acting mediately on the vital properties of the diseased part.—Under this head I include all those agents operating on some one or more parts of the body, which have a relation with the diseased part. Now I have before mentioned that we

make three kinds of relations, namely, the mechanical, the functional, and the sympathetic; and I purpose still adhering to this arrangement in discussing the operation of this class of medicines.

Mechanical relations.—We know few, if any, instances in which the therapeutic effect can be attributed solely to the mechanical relation existing between the vital actions of the diseased part and the organ affected by the medicine, although now and then the effect must, in some degree, be referred to this circumstance. Thus, vomiting may modify the functions of remote organs by the mechanical violence produced; and diseases of these parts may, in consequence, be influenced.

Functional relations.—Every portion of the living body requires two conditions to enable it to carry on life: 1st, the presence of a certain quantity of arterial blood, of a proper quality; 2dly, nervous influence: so that every organ has a functional relation to the vascular and nervous systems; and, therefore, alterations in the quantity or the quality of the blood sent to it, or in the supply of nervous energy, must be attended with corresponding alterations of function. Now we can modify the condition of the blood by varying the quality of food, and, therefore, in a secondary way, the functions of distant organs become affected. For example, it is well known that abstinence from vegetable food, and the continued use of salted meats, give rise to an alteration in the quality of the blood, attended with other symptoms, constituting the disease called scurvy: and we know, also, that the blood will resume its healthy character, and the disease be removed, by the employment of fresh vegetables, and citric or tartaric acids. Hence it seems fair to infer that the beneficial effect of these remedies depends on their improving the quality of the blood. In cutaneous diseases benefit may sometimes be gained by the use of medicines which excite the vascular system generally, and which thereby promote the secretion of the skin: in such cases the therapeutic effects depend on the functional relation between the vascular and the cutaneous systems. So also, when we employ digitalis and refrigerants in inflammatory affections, our object is to diminish indirectly the quantity of blood sent to the affected part, by acting on the general vascular system, and thereby influencing the diseased action.

The effect produced by what is called *contiguous sympathy* must, I think, be sometimes referred rather to a functional than a sympathetic relation. In amenorrhœa, when we are desirous of determining to the uterus, we sometimes effect our object by acting on the vascular system of a neighbouring organ (the rectum), as by aloes, knowing that the vessels of the uterus in consequence receive a greater supply of blood.

In the second place, we sometimes obtain valuable therapeutic effects by modifying the supply of nervous energy to the affected part. Thus, in spasm of the bowels, as also in pain arising from the passage of calculi, great relief is experienced by the employment of opium; which, acting on the nervous system, gives relief by the functional relation existing between this system and the part affected.

Sympathetic relation—*Sympathy.*—Medicines sometimes influence morbid actions mediately under circumstances which cannot be referred either to mechanical or functional relations, and, therefore, we are compelled to call to our aid this unknown relation termed sympathy. Thus purgatives relieve cutaneous disorders and affections of the head; blisters are frequently useful in internal complaints, diaphoretics in affections of the alimentary canal, diuretics in dropsies, &c.

In general, however, the relief obtained does not arise solely from any one mode of action. A purgative administered in an affection of the head may give relief in several ways; by evacuating morbid secretions, which may be a source of irritation; by determining blood towards the bowels, and thereby relieving the cerebral vascular system; by influencing the digestive process, and thereby the quality of blood; and lastly, by sympathy.

FUNDAMENTAL METHODS OF CURE.

Let us in the next place examine the *fundamental methods of cure* which have been adopted and followed in the treatment of disease. According to Hahnemann there are only three possible relations between the symptoms of diseases and the specific effects of medicines—namely, *opposition*, *resemblance*, and *heterogeneity*. It follows that there are only three imaginable methods of employing medicines against disease; and these he denominates *antipathic*, *homœopathic*, and *allopathic*.

Antipathia.—1st. The *antipathic* method consists in employing medicines which produce effects of an opposite nature to the symptoms of the disease, and the axiom adopted is *contraria contrariis opponenda*; hence the origin of the term *antipathic*—from αντι, opposite, and παθος, a disease. We may regard Hippocrates as the founder of this doctrine, for in one of his aphorisms he says, "all diseases which proceed from repletion are cured by evacuation, and those which proceed from evacuation are cured by repletion: and so in the rest, contraries are the remedies of contraries."

We adopt this practice when we employ purgatives to relieve constipation, depletion to counteract plethora, cold to alleviate the effects of scalds, or narcotics to diminish preternatural sensibility. Hahnemann objects to the practice, on the ground that it is only palliative. Whenever we attempt to influence the system by any external agent, say his followers, a tendency to reaction is set up: so that if the primary effects of an antipathic medicine be of an opposite kind to the phenomena of a disease, the secondary effects, or those which arise from the reaction of the system, are similar to the morbid phenomena, and, therefore, only produce an aggravation of the original malady. To all theoretical objections of the kind here offered, our only answer can be an appeal to experience; which, I think, warrants us in frequently ascribing a beneficial influence to this mode of treatment.

Homœopathia.—2dly. The *homœopathic method* was founded by Hahnemann, a German physician, towards the latter end of the last century; but the first systematic account of it was published in 1810, under the title of *Organon der Rationellen Heilkunde.* The true mode of curing a disease mildly, promptly, certainly, and permanently, says Hahnemann, is, in all cases, to select a medicine capable of producing an affection similar to the one to be removed; and he therefore adopts as his axiom, "*similia similibus curantur;*" from whence he has taken the designation of his doctrine—ὅμοιος, like, or similar, and παθος, a disease. The following are some of the statements made by him, in support of his opinion:—The author of the fifth book, Ἐπιδημιῶν, attributed to Hippocrates, speaks of a patient attacked by the most violent cholera, and who was cured solely by white hellebore; which, according to the observations of Forestus, Ledelius, Reimann, and many others, produces of itself a kind of cholera. The English sweating sickness of 1485, which was so fatal that it killed 99 out of 100 affected with it, could only be cured by the use of sudorifics. Diarrhœa is sometimes cured by purgatives. Tobacco, which causes giddiness, nausea, &c. has been found to relieve these affections. Colchicum cures dropsy, because it diminishes the secretion of urine, and causes asthma in consequence of exciting dyspnœa. Belladonna produces difficult respiration, burning thirst, a sense of choking, together with a horror of liquids when brought near the patient; a flushed countenance, eyes fixed and sparkling, and an eager desire to snap at the by-standers; in short, a perfect image of that sort of hydrophobia which Theodore de Mayerne, Münch, Buchholz, and Neimicke, assert they have completely cured by the use of this plant. When, indeed, belladonna fails (which it often does) to cure canine madness, it is attributable, according to Hahnemann, either to the remedy having been given in too large doses, or to some variation in the symptoms of the particular case, which required a different specific—perhaps hyoscyamus, or stramonium. Drs. Hartlaub and Trinks have subsequently added another homœopathic remedy for hydrophobia—namely, cantharides. The best application to frost-bitten parts is cold, either by the use of some freezing mixture or by rubbing the part with snow. In burns or scalds the best means of relief are the exposure of the part to heat, or the application of heated spirit of wine or oil of turpentine.

Such, then, are a few of the statements made by Hahnemann in support of his doctrine—a doctrine which has been facetiously termed, "the art of curing, founded on resemblances; or the letting one nail drive out another." When we bear in mind the great spread of this doctrine on the continent (in the "*Pharmacopœia Homœopathica,*" published in 1834, above three hundred physicians and surgeons are enumerated who practise it); when we find that the French Minister of Public Instruction this year called on the *Académie de Médecine* to report on it; when we see several works (professional and non-professional) published in our own country on the subject, and find it stated in the public prints that an illustrious lady had submitted herself to the practice of an homœopatheker, we cannot refuse to examine it in a serious and attentive manner.

You will naturally be desirous of knowing on what principle, if he have any, Hahnemann explains the efficacy of his medicines. In his opinion, however, it is of little importance to endeavour to elucidate in a scientific manner how the homœopathic remedy effects a cure; but he offers the following as a probable explanation. The medicine sets up in the suffering part of the organism an artificial but somewhat stronger disease, which, on account of its great similarity and preponderating influence, takes the place of the former; and the organism from that time forth is affected only by the artificial complaint. This, from the minute dose of the medicine used, soon subsides, and leaves the patient altogether free from disease; that is to say, permanently cured. As the secondary effects of medicines are always injurious, it is very necessary to use no larger doses than are absolutely requisite, more especially as the effects do not decrease in proportion to the diminution of the dose. Thus eight drops of a medicinal tincture do not produce four times the

effect of two drops, but only twice: hence he uses exceedingly small doses of medicines. Proceeding gradually in his reductions he has brought his doses down to an exiguity before unheard of, and seemingly incredible. The millionth part of a grain of many substances is an ordinary dose; but the reduction proceeds to a billionth, a trillionth, nay, to the decillionth of a grain, and the whole materia medica may be carried in the waistcoat pocket.

The following is the method of obtaining these small doses. Suppose the substance to be a solid; reduce it to powder, and mix one grain of it with ninety-nine grains of sugar of milk: this constitutes the *first attenuation*. To obtain the *second attenuation*, mix one grain of the first attenuation with a hundred grains of sugar of milk. The *third attenuation* is procured by mixing one grain of the second attenuation with ninety-nine grains of sugar of milk. In this way he proceeds until he arrives at the *thirtieth attenuation*. The following table will shew the strength of the different attenuations, with the signs he employs to distinguish them:—

Signs.		Strength of one grain.
1.	First attenuation	One hundredth part of a grain.
2.	Second	One thousandth.
I.	Third	One millionth.
II.	Sixth	One billionth.
III.	Ninth	One trillionth.
IV.	Twelfth	One quadrillionth.
V.	Fifteenth	One quintillionth.
VI.	Eighteenth	One sextillionth.
VII.	Twenty-first	One septillionth.
VIII.	Twenty-fourth	One octillionth.
IX.	Tenty-seventh	One nonillionth.
X.	Thirtieth	One decillionth.

Here is a tabular view of the doses of some substances employed by the homœopathekers:—

Charcoal, one or two decillionths of a grain.
Chamomile, two quadrillionths of a grain.
Nutmeg, two millionths of a grain.
Tartar emetic, two billionths of a grain.
Opium, two decillionths of a drop of a spirituous solution.
Arsenious acid, one or two decillionths of a grain.
Ipecacuanha, two or three millionths of a grain.

These doses are given in pills (*globuli*), each about the size of a poppy-seed. You will, perhaps, hardly believe that it is gravely asserted, the length of time a powder is rubbed, or the number of shakes we give to a mixture, influences the action on the body!! In mixing a powder with sugar, the exact period we are to rub is therefore laid down: in dissolving a solid in water, we are told to move the phial "*circa axin suam*," and at each attenuation to shake it *twice*—"*bis, brachio quidem bis moto, concute.*" But enough of such absurdities.

The principal facts to be urged against this doctrine may be reduced to four heads:—

1st, Some of our best and most certain medicines cannot be regarded as homœopathic: thus sulphur is incapable of producing scabies, though Hahnemann asserts it produces an eruption analogous to it. Andral took quinia in the requisite quantity, but without acquiring intermittent fever; yet no person can doubt the fact of the great benefit frequently derived from the employment of this agent; the paroxysms cease, and the patient seems cured. "But," says Hahnemann, "are the poor patients really cured in these cases?" All that can be said is, that they seem to be so; but it would appear, according to this homœopatheker, that our patients do not know when they are well. We are also told, that whenever an intermittent resembles the effects of cinchona, then, and not till then, can we expect a cure. I am afraid if this were true very few agues could be cured. Acids and vegetable diet cure scurvy, but I never heard of these means causing any disease analogous to it.

2dly, In many cases homœopathic remedies would only increase the original disease. Only contemplate the evils likely to arise from the exhibition of acrid substances in gastritis, or of cantharides in inflammation of the bladder, or of mercury in spontaneous salivation!

3dly, The doses in which these agents are exhibited are so exceedingly small, that it is difficult to believe they can produce any effect on the system, and, therefore, we may infer that the supposed homœopathic cures are referrible to a natural and spontaneous cure. What effect can be expected from one or two decillionth parts of a drop of laudanum? Hahnemann says it is foolish to doubt the possibility of that which really occurs; and adds, that the sceptics do not consider the rubbing and shaking bestowed upon the homœopathic preparation, by which it acquires a wonderful development of power!

4thly, Homœopathia has been fairly put to the test of experiment by some of the members of the *Académie de Médecine*, and the result was a failure. Andral tried the system on 130 or 140 patients, in the presence of the homœopathists themselves, adopting every requisite care and precaution, yet in not one instance was he successful.

The whole doctrine of homœopathia seems to me to be founded in error (or something worse), and to arise from mistaking the *post hoc* for the *propter hoc*. It is a happy illustration of the amusing story told in the *Poggiana*, of a countryman who bought six pills of a quack, which were to enable him to discover his lost ass. The pills beginning to operate on his road home, obliged him to retire into a wood, where he found his ass; in consequence of which the clown soon spread a report of the wonderful success of the empiric, who in consequence, no doubt, reaped an ample reward from the proprietors of strayed cattle.

Allopathia.—3dly, The *allopathic method* consists in employing medicines which give rise to phenomena altogether different, or foreign (neither similar nor exactly opposite), to those of the disease: hence this plan of treatment has been denominated *allopathia*, from ἄλλος *another*, and παθος *a disease*. As it involves the doctrine of *counter-irritation*, I shall defer it until our next lecture.

A PAPER

ON THE

APPLICATION OF COMPARATIVE ANATOMY TO HUMAN EMBRYOLOGY,

Read before the Junior Physical Society, Guy's Hospital, May 2d, 1835.

By John Anderson, M.E.S.
Late Clinical Clerk, Guy's.

[Concluded from p. 79.]

We now proceed to the Mollusca, in whose skeleton not a particle of phosphate of lime is discoverable. With regard to the Acephalous Mollusca, some, as the Tunicata, are protected only by an elastic cartilaginous tunic, varying in form and consistence, and having a respiratory and an anal aperture; others, as the Conchifera, are protected by shells (generally bivalve), composed principally of animal matter and carbonate of lime, secreted by the mantle, a thin tunic covering the body, connected by teeth and ligaments, and having on their internal surface one or two muscular impressions. These animals have a mouth always edentate, but furnished in the Conchifera with tentacula, leading by a short œsophagus to the first stomach, near the pyloric orifice of which the ducts of the surrounding liver open: the length of the intestines is very various. Their nervous system consists (according to Cuvier*) of one ganglion situated on the œsophagus, and generally two further down; from these nerves are given off, the distribution of which is not well known. The sanguiferous system in the Tunicata is simple, the pulsating heart consisting of a mere enlargement of the arterial trunk; but in the Conchifera it is more perfect, more complex. We find a heart, consisting of a ventricle, receiving the aerated blood from a thin muscular contractile auricle, and propelling it by two large aortal trunks through the body. Here, then, we find the development of an auricle; rendered necessary, indeed, to prevent the stoppage of the blood in the venous trunks by the contractions of the ventricle, and to allow a sufficient accumulation of blood during those contractions. The same we may presume to occur in the human fœtus; the previously simple cavity of the heart, equally as in these Conchifera subject to necessity and regulation, becomes now divided—a distinct auricle and ventricle become now demonstrable†. The respiratory organs are in the form of branchiæ, lamellated, tufted, or pectinated, through which rush in currents of water, excited by the action of vibratile ciliæ; these, again, pass out by the anal orifice; thus assisting in the expulsion of extraneous discharges, aerating the blood, and bringing food for the nourishment of the animal.

Passing over the Gasteropoda and Pteropoda‡, we come to the Cephalopoda, the highest of the invertebrate animals. In this class we find both an internal and an external skeleton; in some the shells appear in the form of cones, varying in texture and form, and in the number, communication, and division, of the internal chambers; in others, again, the shell is thin and horny, and internal to the mantle: this latter circumstance is interesting, as exhibiting the rudimentary development of the internal skeleton of the vertebrata: here, also, a rudimentary cranial cavity exists. These animals are carnivorous, and have a mouth armed with two stout horny jaws; the œsophagus swells into a crop, and then communicates with a fleshy gizzard, to which succeeds a third membranous and spiral stomach. The intestine is simple, short, and terminates with a valved orifice. Here is a great advancement in the perfection of the digestive apparatus, differing in form from that in man, but presenting a rudimentary con-

---

* Règne Animal, translated by Griffiths.

† I would rather correct this observation, by saying that an auricle becomes developed; the division of a cavity generally takes place in the formation of the ventricles.

‡ These classes have been fully treated of in my recent investigations.

dition of what we shall find in birds. Their œsophageal ganglia, acquiring the form of a lobed brain inclosed in a more or less perfect cranial cavity, give off filaments to the eye, and two large nervous cords passing backwards; not yet, however, inclosed in a cartilaginous tube. In the abdominal cavity are seen sympathetic ganglia.

The heart consists of an auricle, into which the vena cava pours its contents; this auricle propels the blood into the laminated and pectinated branchiæ, which is then conveyed by branchial veins to a fleshy ventricle, whence it is propelled into all parts of the body. Respiration is effected by the water which flows in by the two sides of the mantle.

We now pass to the Vertebrata, and to them we have been led by the closest analogies; in fact, nature's ascent is by easy gradations, and is obedient to fixed laws. We shall find organization and structural development in them, as in the human fœtus, rising by rapid paths towards perfection, the analogies becoming more and more apparent and important. In the lowest, or cartilaginous fishes, we find traces of an external skeleton; for their bodies are covered with dense white plates, composed of phosphate of lime, a soft, almost gelatinous, vertebral column, and cranium, only being developed internally. This soft flexible state of bone bears an important analogy to the skeleton of the human embryo; there we know that shortly after conception the whole of the osseous system, from being originally in a fluid state, forms a transparent gelatinous mass, which changes into cartilage at different intervals in different bones, the cranium and vertebral column, as in the cartilaginous, and the ribs, as in the osseous fishes, being among the first in which this change takes place. In a fœtus of ten weeks I found the ribs ossified; in one of five months, the cranium the thickness of stiff paper. The osseous fishes have an articulated vertebral column, composed of a denser material, each vertebra being united by concave surfaces filled with a soft substance, and communicating with each other. Many of them have long spinous processes, from which are developed rays of a hard or soft structure, which support the various forms of fins: from the transverse processes are developed ribs. There are also cranial vertebræ (a continuation of the vertebral column to the cartilage of the nose), the first of which is large, and forms, indeed, a portion of the occipital bone*. The cranium, generally of a large size, varies much in form, and consists (according to Cuvier) of twenty-six bones variously united and developed, and formed by the cranial vertebræ: there are teeth, very various as to form and situation.

Here, then, we are advanced a step higher in osteology; earthy matter has become deposited; true bone is formed. The consideration of the number of pieces of bone composing the cranium is interesting, from its analogy to what takes place in the fœtal skull: there, as in the cartilaginous fishes, it is at first a uniform, transparent, cartilaginous case, without sutures. Progressing in development, as in the osseous fishes, it is composed of numerous pieces, the result of ossific deposit shooting like radii from various centres, and forming diaphanous laminæ, with but very little diploë. Again, the anterior extremities are those most perfectly developed in fishes; and this corresponds with their early evolution in the human fœtus, as already described. We have seen, also, that the vertebral column was the first formed part of the skeleton; and this, equally in man as in the cold-blooded Vertebrata, may be regarded as the source and origin of all the other pieces of the skeleton*. The bones of the internal ear are well developed in fishes; and this corresponds with their well-known early formation in the human embryo.

The digestive apparatus in fishes consists of a wide short œsophagus, leading to a capacious stomach, frequently more or less of a spherical form. In the *scomber scombrus* (mackarel) I found it long, and gradually tapering. The pyloric extremity is variously situated; beyond it are the orifices of the hepatic and pancreatic

* This is a subject concerning which I have collected some very interesting particulars, principally from the Anatomie Philosophique of Carus. The vertebral column, strictly speaking, extends from the extreme point of the nose to the tip of the coccyx; the whole skull consists of but six vertebræ, with their arches more or less developed, each element of which is formed according to strict geometrical principles. To give a momentary insight into the assertions just made, I might observe that the basilar portion of the occipital bone forms the body of the first cranial vertebra, the posterior and anterior portions of the body of the sphenoid, the bodies of the second and third, the vomer the body of the fourth. The fifth and sixth have not their bodies developed, but their arches are formed by the cartilages of the nose. In a cold-blooded vertebrate animal, or in a very young quadruped, these parts are permanently detached. I have in my museum the young and separated skull of a horse, where these elements can easily be traced.

* This is a bold assertion, and one which may appear at first sight unfounded; but it is impossible to read Carus without being convinced of its truth. The ribs, for instance, are nothing more than protovertebral arches, to which the segments of the Articulata bear the greatest analogy. The extremities are only radiating tritovertebræ, given off with mathematical accuracy from the deutovertebral arches (the canal for the spinal marrow.)

glands, which latter consist of pyloric cæca, very various as to number and form. I injected them in the mackarel, and found them very numerous, of a lengthened tapering form, and of exceedingly ready communication with the alimentary tube. The intestinal canal varies in length, and terminates in a cloaca; there is but little distinction into large and small intestines, and no true cæcum. Their nervous organs Cuvier describes as consisting of external senses, of a central medullary apparatus, and of nerves which establish their communication. In the lowest cartilaginous fishes are two slender nervous cords, extending along the middle of the back. In order to illustrate accurately the brain of the osseous fishes, I dissected and examined it in three species*. In all it was extremely small, and did not fill the cranial cavity; it consisted of cerebral hemispheres, anterior to which were the olfactory tubercles; posteriorly were situated the optic lobes: these six portions I found particularly well marked in the brain of the eel; the olfactory tubercles were rather more than usually complicated. Here we shall demonstrate many beautiful points of analogy to the progressive development of the human fœtal brain; there, already have we traced out the primary deposition of medullary matter, in the form of a dorsal nervous streak, and have shewn its analogue in the Entozoa and Chondropterygious fishes: progressing, we found a medullary mass observable in the cranial cavity; a rudimentary brain, indeed, analogous to the supra œsophageal ganglia of insects, and, as in them, a commencing division into hemispheres. We shall now find how closely this brain approximates in progress of development to the fishes, to which latter class the Cephalapods themselves have, in their nervous organization, gradually advanced. The cerebral hemispheres of the previously mentioned brain of fishes were small in size, smooth and solid within. In the *gadus morhua* they were situated below the optic lobes, inferior to which, in the median line, was situated a small round body, having a central depression. In the fœtus of five months I found the hemispheres destitute of convolutions; and these in an earlier state contain no cavities, the ventricles being first developed in the corpora quadrigemina, which I found of a comparatively large size in a fœtus of two months: in fishes the optic lobes, their analogues, are largely developed, and contain a cavity where, in the mackarel, a vessel was seen beautifully ramifying. In the fœtus of eleven weeks the olfactory nerves and tubercles are perceptible; and in the osseous fishes these parts are present, varying much in form, size, and position. The cerebellum, destitute of convolutions, is but imperfectly developed in fishes, and in some is almost wanting, though its relative size is somewhat considerable: it consisted in the common cod-fish of an undivided tongue-shaped median lobe, beneath which was the fourth ventricle, communicating with a canal in the spinal marrow. This lobe had no transverse striæ on its outer surface; but in the cartilaginous fishes it is transversely laminated, and rudimentary lateral hemispheres are developed; this I found the case in examining the brain of a species of *raia*. In the very early human fœtus the cavity of the fourth ventricle (formed by the separation of the corpora restiformia), exists as an open cavity, communicating with a canal extending along the spine. Between the seventh and eighth week the cerebellum is perceptible, smooth, and without furrows, its median portion, as in the fishes, being developed before the lateral hemispheres, and the subsequent laminæ on its outer surface being, as in them, demonstrable before the convolutions in the cerebral hemispheres. The spinal cord in fishes is comparatively large (in the cod-fish its transverse diameter nearly equalled that of the brain at its widest part); it is of pretty equal diameter in its length, and from it spinal nerves arise by two sets of roots; this corresponds with the early development of these parts in the human embryo, and the want of the middle and posterior enlargements of the spinal cord, from the extremities not yet being developed. The medulla oblongata is large in fishes, and gives origin to most of the cranial nerves, of which there are eight pair; on it are already perceptible the corpora pyramidalia, olivaria, and restiformia; of these, the former are demonstrable in the human fœtus at the fourth month, the latter as early as the eleventh week.

Fish have a complete circulation, also a renal, portal, and hepatic one, thus advancing a step higher in the development of the vascular system; they have a heart (as was exemplified in the genera *scomber*, *salmo*, *raia*), consisting of an auricle and ventricle, from which latter arises an artery conveying the blood (brought to the auricle by the venæ cavæ) to the branchiæ, which being oxygenated, is returned for distribution by a large branchial vein, the analogue of the aorta in other animals. We thus see that their circulation has an appropriate character, and itself represents the embryo condition of the Batrachian reptiles.

* *Gadus morhua*, *scomber scombrus*, *anguilla* —— ? I have since dissected the brain of the *perca fluvialis*, and have succeeded in tracing out the cranial nerves, with their origins.

Respiration is effected by means of tufted or laminated branchiæ (varying in number and form), situated on each side of the neck, and supported by the os hyoides; there is also in most fish an air-bag, or natatory bladder, of various forms, situated in the median line, communicating with the alimentary canal, and assisting in respiration.

The Amphibia approach, in the form of their skeleton, to the fishes, but the texture of their bones is more compact; and in the cranium there is a tendency to anchylosis and union, a prelude, indeed, (Dr. Grant observes), to the sutures, and reminding us of the increased development of the ossific radii in the bones of the human fœtal cranium, and their consequent nearer approximation. In the higher Amphibia, as in the genera *rana* and *bufo*, extremities and a rudimentary sacrum are developed; there are no ribs, but a circular arch, formed of a sternum in front and two scapulæ posteriorly, separated by small clavicles, support the anterior extremities. In a similar manner are they supported in the human fœtus, and the clavicles and scapulæ are of early formation. Amongst the true Reptilia, the *ophidia*, or serpents, have a pliant though secure vertebral column, from which are developed ribs. The *sauria*, or lizards, have a complex sternum and scapular apparatus, a pelvic arch, and anterior and posterior extremities. The *chelonia*, or tortoises, are shielded in a strong, almost entire, bony case; the teeth are replaced by horny mandibles.

As regards the digestive apparatus, the amphibia in their tadpole state have a large capacious alimentary tube, which I found in the tadpole of the frog to measure four inches and a half in length; this is, however, lessened in size on their metamorphosis. The serpents have a large dilatable stomach and œsophagus, a small cæcum, and convoluted intestines, terminating in a cloaca. In a British species of *coluber*, I found the alimentary canal upwards of three feet in length, and the stomach long and tapering. The lizards have a short simple alimentary canal, as was exemplified in the *lacerta agilis*. The tortoises have a tolerably large cæcum; the distinction into large and small intestines is pretty obvious, and internal longitudinal folds are developed. Our last notice of the alimentary canal in the human fœtus demonstrated it as tolerably perfect with regard to the œsophagus and stomach, and extending from mouth to anus; and now, progressing in development, as in these Reptilia, a marked division into large and small intestines takes place, a rudimentary cæcum becomes developed, and rugæ, the prelude to valvulæ conniventes, are formed.

The nervous system of the Amphibia changes with their metamorphosis; in their tadpole state it passes down through the numerously prolonged coccygeal vertebræ, and presents much the same simple character as in the highest fishes. I found the brain of the tadpole quite a miniature representation of that of an eel; but when their change takes place, the cerebral hemispheres become enlarged, and the optic lobes diminished; the spinal marrow appears to shrink upwards, from the coccygeal vertebræ becoming filled up, and enlarges opposite where the anterior and posterior extremities are given off*. This is precisely similar to what occurs in the human embryo, where a similar retraction and enlargement of the spinal marrow take place, consequent on similar structural and organic changes, as also a corresponding enlargement of the hemispheres, and consequent relative diminution of the corpora quadrigemina. In the other Reptilia, the cerebral hemispheres have still more increased in size; the olfactory tubercles and optic lobes have diminished, but the whole brain is remarkably small: these characters quite agreed with the dissection of the brain of the *coluber natrix*.

The sanguiferous system of the Amphibia presents us with some interesting changes: in the tadpole state they have a heart and vascular apparatus, similar to the fishes, and, like them, they breathe by branchiæ; but as they advance in development, and finally leave the water, their air-sacs are converted into cellular lungs; the artery given off from the ventricle divides into two, by which one-half of the blood is propelled through the lungs, which, returning into a developed pulmonic auricle, and thence into the ventricle, is circulated, half arterial, half venous, through the general system. I have found the heart in the adult *triton cristatus* to present these appearances. In the other Reptilia there is still greater development, especially in the pulmonic system, for both auricles are more muscular, more distinct; they breathe by means of lungs, which are either in the form of equally or unequally developed undivided sacs, or minutely divided cellular sacs, as in the higher orders. Keeping pace with the progressive development of the vascular system, we may presume that in the human fœtal heart, as in these reptilia, a pulmonic auricle now becomes demonstrable; this I found the case in a fœtus of ten weeks, the sep-

* Some of these interesting changes I have since been able to demonstrate by dissection, in the various states of the genera *rana* and ***triton***.

tum between the ventricles being incomplete; in a fœtus of five months, however, it was completely closed up. The development of the organs of respiration in the human fœtus does not seem well understood, and I touch but lightly on the subject. In the embryo state there are simple pulmonary sacs, opening externally by three branchial apertures on each side of the neck, which become subsequently closed up, though Ascherson relates cases where they have remained open, and formed congenital fistulæ *; their use does not appear obvious. We may conceive these air-sacs at first simple, afterwards internally divided into cells, and in progress of development to become as minutely cellular as we know them to be at the termination of fœtal existence. In examining a fœtus of nine weeks, I found what appeared to be an aperture in the larynx opening externally, and one or two imperfect ones apparently, on the left side; the lungs appeared quite solid. In a fœtus of twelve weeks, I found on one side three minute apertures; in six other human fœtuses of various ages I could distinguish no orifices whatever; neither could I in the fœtus of *erinaceus europæus, mus musculus,* and *felis catus.*

In remarking upon the skeleton of birds, the texture and composition of bone have here arrived at their maximum. The earthy deposit has greatly increased, and the bones are compact, brittle, and hollow. The structure of the skeleton is very uniform, and gradually approximates to that perfection of development exhibited in ourselves; the pelvis is lengthened and widened; the vertebræ are numerous; the sternum and coracoid bones are large, and vary greatly in form; the skull is lengthened and tapering; the orbit large; the jaws are invested with a notched or jagged horny substance.

The digestive apparatus (excepting in the carnivorous birds) is very complicated. In the genera *falco* and *strix* I found the stomach simple: in *columba* it was composed of three parts—an immense crop formed by two lateral enlargements of the œsophagus, a membranous stomach with internal glands, and a powerfully muscular gizzard. The intestinal canal was of some length (50 inches); true valvulæ conniventes, as in the human fœtus, were not yet developed; there were two cæca coli, and the rectum terminated in a cloaca, into which also opened the spermatic ducts and ureters. In birds this cloaca is the prelude to the more perfectly formed urinary bladder of the Mammalia. In the early human fœtus I have demonstrated a similar pouch or cloaca, which, in a like manner, Dr. Grant observes, "may be considered the rudiment of, and is indeed, that same part of the intestine which develops the bladder, while the rectal pouch, being prolonged posteriorly, terminates in a true and distinct anal opening." The brain of birds is proportionally large, and, as in the human fœtus, now fills the cranial cavity. The optic lobes and olfactory tubercles are diminished, from the increase in size of the smooth, still unconvoluted, cerebral hemispheres, which contain but small cavities, and in which are now perceptible the thalamus and corpus striatum, with diverging fasciculi crossing the median line, the rudiments only of the corpus callosum of the Mammalia; these parts I observed in the brain of a species of *columba.* The same occurs in the progressing human fœtal brain. The corpus callosum is of late formation (I found only the rudiments of it at the fifth month); the hemispheres are much increased, but yet without convolutions; the lateral ventricles, with their contents, are developed; and in the fœtus between the fifth and sixth month, I found present the corpus striatum and thalamus. The cerebellum, with its lateral hemispheres, is enlarged in birds; and transverse sulci, dipping into the interior, are distinctly seen on the surface. This was beautifully demonstrable in the brain of *phasianus gallus* and *columba,* and quite corresponded with the progressive development of the cerebellum in the human fœtus, where, at the fifth month, I found the lateral hemispheres formed, and a few transverse furrows presenting themselves on the external surface. In the spinal marrow of birds the middle and posterior enlargements are distinctly manifest, the reason and analogy of which are obvious: the great sympathetic is also highly developed *. As regards the heart, the ventricle being divided by an impervious septum, this organ has now arrived at its most complicated form, such as it presents in the mammalia and the human fœtus, when commencing the era of a separate existence. The respiratory organs of birds consist of fixed lungs, and of communicating air-sacs, situated in the abdomen, neck, and extremities. Similar air-cells exist between the muscles; and when we consider that the bones also are hollow,

* In a memoir lately published in Latin at Berlin, "On the Branchial or Gill-like Openings in the Neck of the Human Fœtus, as a Cause of certain Malformation." See Cuvier's Règne Animal, translated by Griffiths, vol. ii. p. 411.

* Having lately had the opportunity of dissecting the brain of some other species of birds, I have noticed, by accurate measurements, that the cerebrum and cerebellum are larger in proportion to the optic lobes in carnivorous than in graminivorous birds; in which anatomical peculiarity physiology fully bears me out.

and contain air, we see, as anatomists, how highly organized and extended is their respiratory apparatus; we observe, as physiologists, how indispensable this is to their structure and habits. A diaphragm, composed of small muscular bands, shooting upwards from the ribs over the surface of the lungs, is observable in all birds, analogous to the rudimentary development of this muscle in the human fœtus, and which at five weeks I found scarcely at all developed; at ten weeks, quite a thin membrane; at five months, a firm muscular structure.

We have now arrived at the last and the highest class of the animal kingdom—the Mammalia—at the head of which stands man, so justly styled "the lord of the creation *." In them there is a greater uniformity of plan as regards the skeleton; the bones in texture are more fibrous than in birds; there is a larger proportion of animal matter; their cavities are filled with marrow, and it is needless to say they more or less resemble the human adult bone. Perhaps the greatest osseous structural difference will be found in the *cetacea*: there the vertebral column is prolonged greatly backwards; there are no posterior, and the anterior extremities are but imperfectly developed. These animals, observes Dr. Grant, are interesting emblems of the embryo of our own species, in the texture of their bones, in their want of posterior extremities, and of cavities in the long bones of their imperfectly-developed arms. With the general osteological characters of the other orders of mammalia we are familiar. It would have been interesting, had time permitted, to have traced out the elements of the human hand and foot in the extremities of various quadrupeds, the gradually diminishing ferocious characters of their teeth up to the comparatively harmless ones of our own species, and the particular structural dependence of those teeth upon the graminivorous or carnivorous food of the animal, up to those forms indicated by the omnivorous food of man.

The digestive apparatus of the mammalia is highly developed, and presents numerous varieties intimately connected with the habits and food of the animal, and the structure of its teeth. It consists, speaking generally, of an œsophagus, leading to a variously-shaped stomach, which I have found presenting a simple (and more or less resembling the human) form in about twelve of the higher mammalia. In the *sheep* it was of a peculiarly complicated nature, consisting of four parts, and adapted to the ruminating habit of the animal. In the *pachydermata* and *marsupialia* it was internally divided. The intestinal canal (free from valvulæ conniventes, as in the human fœtus), I have invariably found short in the carnivorous, long in the herbivorous, quadrupeds. In the former the cœcum was small or wanting; in the latter, very large. The appendix vermiformis is generally present in the mammalia, and forms in the lower orders, as in the human fœtus, the rudiments of an adult cœcum. I found it well developed at five months, and the cœcum small.

The nervous system is now fast approaching to its maximum of development, making many rapid strides of advancement through the variously-organized mammalia. The great sympathetic is now fully developed; the commissures of the cerebrum and cerebellum, the corpus callosum, and pons varolii, are now demonstrable; the cerebral hemispheres become larger, and their convolutions deeper and more numerous, as we approach the human species; the cineritious matter is less abundantly proportioned to the white fibres. The corpora quadrigemina (large in the lower orders) diminish in size as we ascend the scale, and the ganglia on the symmetrical sensitive nerves become enlarged and approximated. Still, however, the lateral ventricles are smaller, and there is a less extension backwards of the cerebral hemispheres than in the human brain, where, indeed, various structural and organic differences (as we all know) exist, corresponding with the increased energy of man's intellect and the superior vigour of his mind.

The heart and vascular system are on the same general plan as in the birds; but it has here arrived at its maximum of development; and even here many interesting modifications are observable. In the herbivorous *cetacea*, the heart is of a flattened form, and presents at the apex between the ventricles a cleft appearance, produced by the drawing up of the internal septum. A similar one exists in the heart of the human embryo in the early division of these cavities; and at the termination of fœtal existence, when the various familiar changes of the vascular system take place, then does it present the same structural development of the higher mammiferous quadrupeds.

The lungs of quadrupeds are highly cellular, and respiration is more immediately confined to them. The muscular partition formed by the diaphragm is here completed, as in the advanced human fœtus, in which a similarly cellular lung

* The mammalia here are treated of quite superficially, for reasons assigned at the commencement of the paper. More recently I have dissected the different organs in almost every order of this class of hot-blooded vertebrata, and have described their anatomical peculiarities.

is now ready to obey the mandates of separate existence.

Disease also is common to man and other animals, but modified in them according to their organization; thus forming another pleasing analogy. The tubercular deposit, which I before mentioned as first occurring in lepidopterous larvæ, passes through its phases of development in the scale of animal life, until it arrives at its most complicated form in man. According to Dr. Reynaud*, almost all the Quadrumana brought to this country die tuberculous; and I have myself had an opportuity of examining a species of *simia* in which this was the case †.

Thus, then, in conclusion, I have traced up the gradual development and perfection of the most essential organs and systems (those of generation excepted, from want of time only); and I have by that investigation illustrated their progressive evolution in the human embryo and fœtus.

In detailing these investigations, it has been my endeavour to make the subject of as much general interest as possible,—rather to state general than minute analogous anatomical facts, and to confine myself to those, in preference to building up physiological hypotheses. Many of those facts have been obtained from actual dissections, some made expressly for this paper; and I terminate with the hope that when the nature and extent of the subject are considered, the time of the society will not be grudged,—the lash of criticism will fall kindly. Those analogies that may have been the result of my own observations I offer with diffidence, and for the general imperfections and omissions I must indeed plead guilty; but, let me ask, have not even these investigations shewn the high interest, not to say positive importance, of comparative anatomy and physiology? Inasmuch, then, as the permanent structure of the varied kinds of lower animals has an analogous relation to man's gradual fœtal development, who shall say that comparative anatomy does not unfold to us numberless important facts? Who can say that its study is not intimately blended with our other professional duties? Let us be assured it is; and that while we are at the same time perfecting our knowledge of the human body, and thus administering to its relief in disease, we are enlarging and expanding our minds with the great truths of nature, by the combinations of which we more clearly prove the existence of a God, and redound to the glory of an all-wise Creator.

George-Street, Richmond,
Sept. 22, 1835.

* In a memoir read before the Academy of Medicine, Paris, and published in the Archives de Médicine, vol. xxv. p. 149—171, and p. 301—326.

† Since this paper was read, I have had the opportunity of dissecting the *simia satyrus*, Lin. (Orang-outang), which has recently died at the Surrey Zoological Gardens. The lungs were quite tuberculous, but the liver, spleen, and kidney, were healthy. While on this subject, I may remark, that through the liberality of our treasurer, and the kindness of Mr. Bell, the dissection of this rare animal has been entrusted to me. I have preserved every part deserving of notice, and shall not fail to take an early opportunity of making known every anatomical peculiarity connected with so interesting an animal.

ON THE CLIMATE OF MADEIRA,

AND ITS TRUE VALUE TO THE CONSUMPTIVE.

To the Editor of the Medical Gazette.

Sir,

Owing to the progress of the cholera in Italy, and the consequent quarantines, many individuals are thinking of spending the winter in Madeira. Having been in the island last winter, on account of my own health, I trouble you with a few remarks which may, perhaps, be useful to some at this moment.

The situation of the island in the midst of a very large ocean, the latitude, the position of the town of Funchal, &c. all tend to produce great uniformity of temperature and great moisture, by the common principles of meteorology. The moisture is, of course, little seen in the town itself, being kept in such perfect solution by a uniform temperature, but it is generally visible, in the shape of a fog, on the side of the mountain above, whilst its existence is certain below, not merely from theoretical reasoning, but from the observations which have been frequently made there; particularly from the full and scientific tables of Dr. Mason. I avoid, however, all theoretical reasoning, both regarding the climate and also disease, at present; wishing merely to give a few practical hints as shortly as possible. I therefore only add that the feelings of all persons when they first go, both sick and healthy, those benefited and those not, fully bear out the meteorological conclusions. Hence the climate is extremely useful to those patients who suffer from a dry irritable state of the mucous membranes, whether local or general; and in order to avoid a detail

of symptoms, I may express them all under the *strictum* of the ancients: they are well detailed in Dr. Clark's work on Climate; and he recommends Devonshire, Guernsey, Jersey, &c. for them, and it is for these symptoms that I recommend Madeira; a winter here being, in many respects, a summer in those places. On the other hand, I am very anxious to express my strong conviction that, in the opposite class of symptoms, the *laxum* of the ancients, particularly if there are present symptoms of increased mucous and still more of purulent secretion, hemoptysis, a tendency to relaxed, or what is called a slippery state of the bowels, if moist and emollient treatment have disagreed before, that in all these cases the climate will do harm in proportion to the good in the contrary: it will, indeed, often, in cases of general constitutional relaxation, do good at first, by removing some local irritation brought on by disease—as a dry cough produced by tubercles—but it will subsequently increase these by increasing the constitutional disorder which was connected with their formation. Such patients, therefore, must change their climate just as they would change their medicine, with change of symptoms.

All that Dr. Clark has said about the impropriety of sending patients in the advanced stage of disease is quite true; and I am only anxious to follow out his remarks by saying, that not only must the symptoms be slight, but they must also be of the peculiar character I have mentioned. The vague idea that Madeira has the finest climate in the world, and therefore is applicable to all cases of lung disease, is just as absurd as a similar notion about any valuable medicine; and the idea has hastened the death of many who might have long lived by means of a dryer air, slight tonics, &c. It is important also to recollect that this dryer air is not to be found in the island: the higher grounds are very generally covered with fogs in winter, and the few houses there are in summer occupied by the owners; besides that, the air does not become drier as we ascend, but only cooler; at least it remains equally near the point of saturation, which is a very important distinction. Hence the invalid must look to the town, and to it only, as his residence; and consequently eight out of ten must leave the island in summer, or their symptoms will be aggravated, as consumptive symptoms so often are in very hot weather, and as has happened to a friend of mine who remained in the island this summer. The town of Funchal (and it is the only one) was full last winter, and should the cholera send more persons there now, it is probable that great inconvenience will be felt by many. The voyage there, and still more the difficulty of getting home, is a much more serious thing to an invalid than those who have not shared in their sufferings imagine: many certain, and more contingent evils, both moral and physical, beset the patient from the moment he leaves home till he reaches it again; and these ought, as far as possible, to be explained to him. If tubercles, in however slight a degree, are known to exist, let him be told what is the utmost climate can do for him, or his distress will be very great, when, far from home, all the Utopian delusion connected with the word Madeira is torn from him. Here, however, I must strongly recommend the perusal of the first and second chapter of Dr. Clark's work, in which he insists on the care necessary in diet, clothing, medicine, &c. &c. for those who go abroad: the negligent way in which many patients are sent off, with no other advice but to give up all medicine, and trust to that ill-understood thing "climate," is, I know, the cause of irretrievable mischief. The patient very naturally persuades himself that climate will compensate for every imprudence, instead of being, at best, but the most favourable opportunity for care and good treatment. A winter in Madeira is, to all practical purposes, but a summer in Devonshire or Jersey; whilst there are many peculiarities in it which make care in all the common habits of life still more necessary. Recommending, as I do very strongly, Dr. Clark's work, to all who travel for health, he will, I hope, allow me to say that I think he has over-coloured Madeira, and I must suggest two hints to his readers: that Madeira is, with few exceptions, fit for a winter residence only, and that it does not combine the advantages of two kinds of climate, but must strictly be classed with the warm and moist; as Pau, Devonshire, &c.

I have intentionally dwelt more on the evils than good of Madeira, in this short letter; my object being to prevent

those who were going to the dry bracing air of Nice, &c. from ignorantly turning round with the idea of finding it at Madeira; this being, in fact, just the contrary. My difficulty in writing has been not to dilate, and I would gladly at this moment state the advantages of the island: this I may probably hereafter do, in conjunction with one or two friends; whilst I must for the present be content to say that the good, in well-selected cases, is proportionate to the evil in the contrary; and to shew that I am impartial, I may add that it is not improbable I may, before the winter is over, go back to the island myself.

I remain, sir,
Your obedient servant,
J. M. Calvert, M.D.

Frankfort, Oct. 6, 1835.

EXTRAORDINARY WOUND OF THE SCROTUM AND ABDOMEN,

TERMINATING FAVOURABLY.

To the Editor of the Medical Gazette.

Sir,

I am induced to send you a rough sketch of the following case of lacerated and punctured wound, in hopes (if you think it sufficiently interesting) that you will find it a corner in your valuable journal.—I am, sir,

Your obedient servant,
William Ilott.

Bromley, Kent,
Oct. 13, 1835.

On the 13th of August, I was sent for to see Thomas Langridge, a labourer, who it was reported had been wounded by a pitchfork, which had entered into his bowels. On arriving at the man's house (whither I was told he had been conveyed), and making an examination, I found a lacerated wound on the left side of the scrotum, near the septum, about an inch in length and three-quarters of an inch in depth; there was also a contusion of the abdomen, near the cartilage of the seventh or eighth rib, on the right side. The abdomen was tender, and the man complained of great exhaustion, but the pulse was firm and good; and the general complexion of the case led me to conclude that the extent of the injury had been overrated—that the instrument, in fact, had first wounded the scrotum, and then passed up inside of the clothes, but outside of the skin, as far as the point where I had observed the contused mark. The man, however, was full of the idea that the pitchfork had entered into his belly, and mentioned, as a confirmation, the extreme difficulty with which it had been extracted by the men who came to his assistance. As these persons were absent, I thought there was no criterion so good as the general complexion of the case; and this led me to a directly opposite conclusion. I may as well here give an account of the manner in which he described the accident to have occurred. He found it necessary, it appears, to descend from the top of the stack to a lower part, and to ease himself down, he threw the pitchfork first, so as to make it stand upright on the forked end, and used the handle to break the force of his descent; but his hand slipped, and the scrotum came with such force on the end of the handle, that it entered into the cavity of his abdomen.

I dressed the wound in the scrotum with strips of adhesive plaister, took sixteen ounces of blood from his arm, applied a saturnine lotion to the abdomen, and gave him an aperient dose. On the following day I found him labouring under fever, but the wound was quiet, and the abdomen free from pain or tension; I therefore, in addition to the use of the lotion, merely ordered some stronger aperient medicine, as the first dose had not moved the bowels.

On the 16th the febrile symptoms were aggravated; the abdominal pain was very acute; and there was now on the skin a line of intense inflammation, an inch and a half in breadth, extending from above the left abdominal ring obliquely across, till it terminated nearly at the same point on the opposite side, where I have described the contusion to have been in the first instance. In addition to the lotion, I ordered a combination of saline medicine, with opiates.

On the following day the symptoms were not relieved; the man complained of intense pain, and got no sleep. I could also, as I thought, feel a slight fluctuation. I increased the dose of opium, and ordered the lotion to be superseded by warm fomentations and a large linseed poultice.

I now somewhat doubted the correctness of my first opinion; I therefore removed the plaister from the wound (which required dressing), and examined the depth of it, to ascertain if it led up to or near the abdominal ring; I could, however, only pass the probe about three-quarters of an inch in that direction; and I still felt convinced that there could not have been any actual laceration of the abdominal parietes.

From this time to the 23d the symptoms of extensive suppuration became every day more distinct; the patient suffered severe pain, which required the frequent exhibition of opiates; there was a high degree of fever, and the bowels were with difficulty kept open by the constant use of purgatives. There was also sloughing of the cellular substance at the scrotal wound, which of course had made no progress towards healing.

By the 23d the abscess had attained a very great size, and the extreme tension of the skin was a source of constant distress. On the morning of the above day the skin gave way midway between the scrotum and eighth rib, and a small quantity of pus found exit, by which he was in a slight degree relieved. On my visit I gave vent, by pressure, to about half a pint of healthy-looking, but insufferably fœtid, pus. By this a good deal of relief was afforded. I took care every day to empty the abscess as nearly as possible, by pressure, and thus a great quantity of matter was discharged, so that any enlargement of the original orifice did not appear expedient. He was directed to lie chiefly on his left side, and sometimes raise his buttocks by pillows, by which the opening became, as much as possible, a dependent one, and the exit of the pus was much facilitated.

On the morning of the 31st he described himself as completely relieved (for the first time since his accident) by having the matter entirely drained from the wound; and his wife exhibited to me a piece of straw, about half an inch in length, which had that morning issued from the wound, mixed with the discharge! Here was now convincing proof that the extent of the injury had not been originally overrated by the patient; that, in fact, the handle of the fork actually had passed up from the wound of the left scrotum, near the abdominal ring, and had followed the track afterwards occupied by the abscess till it reached as high as the seventh or eighth rib on the right side! How this could have occurred with so slight an external wound does not appear so easily explained.

Thinking it right, for obvious reasons, to have a capacious aperture, I enlarged the orifice to the extent of an inch above and below. The man was much relieved thereby, and the abscess was for the first time entirely emptied; but from this time to the end of the case no more pieces of straw came away. Having seen the men who witnessed the accident, I found, on inquiry, that the pitchfork, when removed, was almost free from blood; but they added, that the testicle on that side was entirely denuded, by the very forcible retraction of the skin.

After the escape of the straw and enlargement of the opening, the man's progress towards recovery was so rapid, that in three or four days the only discharge was a little very thin pus, and the pain and constitutional irritation had quite subsided.

By the 12th of September the abdominal wound had completely healed, and that in the scrotum nearly so. There remained under the skin of the abdomen a space of about a foot in length, evidently hollow: to expedite the closing of this, I directed him to wear a broad linen belt, pretty tightly fastened, over the seat of the abscess. About a week since he called on me, when his wounds appeared entirely healed, and he expressed himself quite able to return to his occupation in a few days.

Remarks. — The most remarkable features in the above case are, first, the occurrence of so extensive and dangerous a punctured and lacerated wound without greater external marks of laceration, and without being followed by constitutional irritation of the most alarming kind; in the next place, the rapid and complete recovery of the patient; and lastly, the difficulty of reconciling the disproportion between the size of the scrotal wound and that of the instrument to which it gave admission, as well as accounting for the precise manner in which the handle penetrated to so great an extent, without wounding either the vessels and nerves connected with the

abdominal ring, or any of the other important parts near to which it must have passed. The fact of its entrance cannot, however, I think, be for an instant doubted, after the discovery of the straw midway between the scrotum and chest.

I think the case may prove both interesting and instructive to the profession; but it would be superfluous for me to point out in what manner it may be so. I therefore submit it to their perusal, through the pages of the Gazette, without further comment.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Practical Observations on Diseases of the Heart, Lungs, Stomach, Liver, &c. occasioned by Spinal Irritation: and on the Nervous System in General, as a Source of Organic Disease. Illustrated by Cases. By JOHN MARSHALL, M.D.

"THAT many in the profession will be found to cavil at the opinions I have advanced, and the facts I have adduced, I make little doubt; but, conscious as I am of the general strength of my position, and the purity of the motives which have induced me to lay the present work before the public, I shall endure with great indifference the *ephemeral* remarks and opinions of such persons."—Page 149. These are the last words of Dr. Marshall; they belong to his preface. When Gulliver fell into the milk-pot, at Brobignag, he of course thought it was very deep. There is something unpleasing in the self-importance which never appears in print or in public without expecting universal hostility.

Surely he must fancy himself an apostle, who never leaves his cell save in expectation of the fate of

> "That bless'd saint, who doffed his skin, to make
> The Smithfield rabble leap from their's with joy."

We like not the bullying—"who's afraid?"—of such defiers of criticism. It betrays a consciousness of something peccant, which, as it cannot be defended, is affected to be despised.

The author had better omitted any allusion to the purity of his motives, until they were impugned: nevertheless we challenge the *disinterestedness* of publishing 172 pages 8vo. for 6s. 6d. We would not muzzle the ox while treading out the corn, but this justice by no means extends to eating out the whole harvest. In this work there is neither novelty nor originality. A system so important, with such universal relations to others, as is the nervous system, cannot play a subordinate part in the production of disease; nor escape with impunity when the vascular system is primarily affected. All this is well known; and he must be deep in the prophets who shall make clear and perspicuous the *modes* of derangement of any part of the nervous system.

Changes in the structure can be detected only by dissection; and we go all the way with Dr. Marshall, who says—"I continued to cultivate the study with the same ardour, never in any instance neglecting a *post-mortem* examination where it was possible to obtain it. The more assiduously I pursued it, however, the more fully did I become aware of the truth, that morbid anatomy, however indispensable to the scientific practice of our profession, never could be to me, or any other physician, the *infallible* guide to diagnostics I had so fondly hoped to find it. Constantly did cases in private, as they formerly had in hospital practice, come under my observation, where, on *post-mortem* examination, no lesion or structural disease was found adequate to account for the symptoms during life; and again, not a few presented themselves where severe lesion and structural disease had actually existed, and no complaint had ever been made during life which could have led to the suspicion that such was the case." When will the day come on which it will be admitted that morbid anatomy exhibits nothing but the *exuviæ* of disease? Nor is this without interest and instruction, but assuredly not of the kind commonly supposed and anticipated. To diseases of the nervous system generally these observations apply with peculiar force; for the majority, even when fatal, after years of duration, oftener astonish by the absence of appreciable change of structure, than instruct by its presence.

On these points Dr. Marshall has some sensible and well-expressed observations; but his delusion must be great indeed if he thinks they are novel.

"Vascular energy is wholly derived from the nervous system. If by any means the nerves destined to supply any vessel, or set of vessels, with this energy, become debilitated or destroyed, then these vessels cease to be capable of duly performing the function of propelling the fluids to and from the heart; and therefore it inevitably follows that turgescence, more or less severe, takes place, and results in disease, depending upon the organ affected for its particular character. Thus a sudden temporary suspension of nervous energy in the vessels of the brain, rendering them for the moment incapable of propelling forward the blood, may occasion giddiness, dimness or distortion of vision, loss or faltering of speech, and all the other well known symptoms of approaching apoplexy: and if these symptoms are neglected, this temporary becomes a lasting loss of energy, producing either immediate death, or a total suspension of vital power in the parts dependent upon the debilitated nerves.

"It is well known that in many cases of apoplexy suddenly terminating in death, no morbid appearance whatever can be detected in the brain. From analogy, I am inclined to believe that there are cases where the interruption in the flow of nervous energy has been so sudden and complete as to arrest the circulation, without giving time for any visible turgescence to take place; and from minute and careful investigation of all that can be collected from surviving friends of the circumstances preceding such cases of sudden extinction of life, I am strongly inclined to believe that such never occur without previous warnings, however these may have been disregarded by the ignorance, heedlessness, or fool-hardiness of the individual. It must be obvious that, the vessels having once become turgid, if the nervous energy be not revived with force sufficient to restore perfectly the balance of the circulation, congestion, and in most cases effusion on the brain, must finally ensue."

The sensations and other effects of irritation at the sources of nervous supply being referred to remote rather than to contiguous parts, is, as is well known, as old as the hills.

It would be injustice towards the author to omit that he pretends to no peculiar practice in his treatment,—which is rational, and upon general principles. This disclaimer goes no farther, for he evidently exults in a superior diagnosis with less humility than beseems a philosopher. We see nothing in the details of the sixth case to make it desirable to veil in the flimsy disguise of *medical* Latin some very ordinary matters; especially as the *names* of the parties are not given. We do not charge upon him the gravest literary offence — pedantry without learning; but it cannot be forgotten that one swallow does not make a summer. We join issue with Dr. Marshall on the "purely nervous origin" of phlegmasia dolens. Its pathology is as well known as that of any disease; phlebitis of the femoral or iliac vein, sometimes complicated with similar disease in the veins of the uterus.

Medical practitioners are too frequently but sorry logicians—*e. g.* "*one fact carefully noted and faithfully reported, is of more value than whole volumes of theory and hypothesis.*" Theorising is reasoning; and of what use are facts if we reason not on them? —it is the use and application of facts; the fact on which we reason not is a *caput mortuum* in ratiocination.

We never heard a man of talent and acuteness repudiating theory: perhaps upon the principle that the handsome and well-formed never decry beauty and the graces; but we have known people as lovely as Quasimodo, or an Ogre, descant on the nothingness of "beauty," and wind up with the original apophthegm—that handsome is, that handsome does! It is worthy of remark, that the contemners of theory are persons notable for a habit of generating crude hypotheses, to which they cling as tenaciously as a pediculum, while they are as intolerant of dissent as a Jew or an inquisitor. Long will it be ere—if ever—we shall be able to contend against the fact that the detection of disease is purely an affair of *observation*, and its cure little else than one of *empiricism;* although neither is the less valuable on that account. This will give but little offence to enthusiasts, if they take care

not to confound empiricism with *quackery*. Nor will the seeker be disheartened, if he remember that diagnosis and therapeutics come not by inspiration.

Practical Anatomy of the Nerves and Vessels supplying the Head, Neck, and Chest. By Edward Cock.

Compendium of the Ligaments; illustrated by Woodcuts. By A. M'Nab, Junior.

Here are two little works which we think will be found particularly useful to the student of practical anatomy. Mr. Cock has acquitted himself in a creditable manner: the method adopted in treating his complicated and difficult subject, shows that he has profited by his experience as a teacher. Mr. M'Nab gives a large quantity of information in a condensed and very concise form. His woodcuts we do not like; but it is not of much consequence, as the book is chiefly intended for a guide in the actual business of dissection.

MEDICAL GAZETTE.

Saturday, October 24, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
Cicero.

PHRENOLOGY IN A QUANDARY.

A Scotch journal, called the *Phrenological*, has attempted to defend the awkward and indecent transaction which took place in Dublin about two months ago. It will be recollected that, at the last meeting of the British Association, a busy little crew of *phrenologists*, ever on the watch to attract some public notice, contrived to get possession of the skull of Swift. They say as much as that they came honestly by it: that it was almost thrust upon them, and that they only improved the *opportunity*.

"In making some alterations *on* the building of St. Patrick's Cathedral at Dublin, it was found necessary to shift several coffins, among which were those containing the remains of Dean Swift and Mrs. Johnson (better known as Stella). The Rev. Henry Dawson, Dean of St. Patrick's, with his usual *liberality* and *anxiety for the advancement of science*, allowed Dr. Houston to [open the coffins and] remove the skulls of *these two celebrated persons*, in order that drawings and casts of them might be made, and *that they might be submitted to phrenological examination*; under an engagement that they should be duly restored to the coffins. Mr. Combe *luckily happened* to be in Dublin at this time, attending the annual meeting of the British Association for the Advancement of Science; so that he had an *opportunity* of examining the actual skulls."

Of the usual liberality and love of science of the Rev. Mr. Dawson, we profess to know nothing; but we believe there will scarcely be two opinions entertained regarding the decency of his conduct in the occurrence just stated. He allows the remains of the most illustrious of his predecessors—of him who gave an importance which it would never have otherwise attained, to the title of Dean of St. Patrick's—to be rifled in their resting-place, and the skull to be removed for the purpose of being submitted to phrenological investigation; and this is called "liberality, and anxiety for the advancement of *science*"! When Swift contemplated his own death, and wrote that touching epitaph which used to mark the spot where his bones *were*, his warmest wish was that he might at length rest "where indignation could no longer lacerate his heart." How little could he have thought that his grave was to be ransacked by a parcel of buzzing busy-bodies, and his head abstracted for the indulgence of impertinent curiosity!

But "Mr. Combe luckily happened to be in Dublin at the time." How very lucky!—especially when we know

that Mr. Combe attended the Dublin meeting as phrenological missionary in chief, and that if a scene could not be got up in which he could take a part, phrenology must have remained in the same abeyance at Dublin this time as it did at Edinburgh last year. How fortunate, then, that he should have had the opportunity of examining the skull!

Let us see, however, what he and his companions made of the said skull. Swift was always a stumbling-block for fools, and he seems to continue to be so nearly a century after his death. He was the scourge of blockheads: oh, that he could have had any conception of the advent of phrenology! But this remained for happier and more *scientific* days.

We have no intention of tiring our readers with the detail of the skull-measuring, nor of filling our pages with the long list of faculties—35 in number—discovered to be either "large" or "very large," "full" or "rather full;" we will just give a few of them, by way of specimen, and we doubt not the reader will at once see how *exactly* they suit the character of the Dean. How could any set of men be so demented as to publish facts so damning to their doctrines?

"Amativeness, large.
Philoprogenitiveness, large.
Love of approbation, very large.
Benevolence, small.
Ideality, small.
Wit, small (skull thickened here).
Imitation, rather full.
Number, moderate.
Language, large (skull very thin).
Comparison, moderate.
Causality, moderate (skull thickened)."

Now who is there that knows any thing of the life of Swift that will not, on glancing over this table, be immediately convinced that either phrenology is *an impudent lie*, or that this could not have been Swift's skull? One or other inference is unavoidable, when the facts are tested by the rules of ordinary reason. The phrenologists, however, have not a doubt about the identity of the skull, and make the best attempt they can to remove the difficulties which it presents them with.

One worthy, upon viewing the astounding contradictions offered by the head, saw no better way of accounting for them than by cutting the Gordian knot at once: he suggested "that the *extraordinary powers of mind* which Swift exhibited on many occasions, might have arisen *from diseased activity*." Did this "learned Theban" ever take the trouble to inquire what were the powers of mind possessed by the illustrious Swift? If he did not, his ignorance and his folly are deplorable: if he did, we leave it to *phrenology* to account for *such* powers being the result of "diseased activity."

The writer of the article on this subject in the Phrenological Journal, assumes a position equally absurd; he contrives, however, to set up two or three hypotheses, to secure for his friends some plausible kind of retreat. He admits that at "the first blush," it seems irreconcileable that "the caustic and powerful Swift" should have had "a skull with small intellectual and large animal indications;" but he doubts not that, on a closer acquaintance with the case, "it will be found to harmonize in all its features with *the phrenological philosophy!*"

The first ground alleged for the apparent contradiction between the *developments* of the skull and the mental powers of him to whom it belonged, seems to be, that this was the headpiece of Swift *old* and *diseased*. The writer assumes that in the latter years of Swift's life his skull became greatly altered in shape and structure: he has even the

boldness to say, "*we know* that Swift was for years *idiotic in intellect*, and that even so early as 1734 (*eleven* years before his death) his memory became imperfect," &c.; and he infers hence, with all the *vis consequentiæ* of phrenology, that the work of disease, and the change of structure in the bones of the head, had thus early begun. *We* know that Swift was reduced for the *four* or *five* last years of his life to a state of dementia—that is to say, from about the 74th to the 78th year of his age; but we utterly deny that there is any warrant in his previous history to make it likely that such organic changes as those gratuitously assumed by our phrenological advocate could possibly have been going on. The very supposition is absurd. It takes for granted—on the mere ground that his memory was beginning to fail, and his temper to be unusually violent — that his skull from being a proper skull (phrenologically speaking) changed its shape and consistency into what the Dublin seers found to be such a difficult nut to crack. It takes for granted that at the age of 67, not only may a skull shrink and become more compact (which we do not gainsay), but that it may *grow thick* over a shrunken *organ* of the brain—the said *growth* being normal, and exhibiting no appearance (so far as we are informed) of exostosis, or disease. But we deny — we repudiate — the whole hypothesis; we reject it in the lump.

It was not till the year 1736 that Swift gave up all interference in public affairs—though, as is well known, he continued to take a warm interest in them up to the period of his expiring reason,—and it was in that very year that he produced his "Legion Club," the wittiest and most forcible satire perhaps ever written. He was then in his 69th year. Nor let it be supposed that here ended his contributions to the world of letters: his "Verses on his own Death," his inimitable "Instructions to Servants," and other most humorous shorter pieces, were produced after he had passed even his 71st or 72d year. Messrs. Phrenologists, explain away these facts if ye can: show that the bones of a man's head might be changed into a shape resembling those of a *changeling*, while the said man was not only not idiotic, but the actual author of some of the wittiest things in our language. If ye contend, that perhaps these changes occurred afterwards—that is to say, during the last three or four melancholy years of the Dean's life, we leave you in the hands of the pathologists; they will settle the matter with you.

But what shall we say to the attempt made to reconcile the bony *developments* to the character of Swift; or rather to pervert his character, so as to make it match the developments detected?

"It is curious," says the writer referred to, "to notice the coincidence between the development of many of the organs of the propensities and sentiments, and the Dean's habitual manifestations during life." Upon which he proceeds to remark, that Firmness is large, and Combativeness is large, and so forth; but not a word about most of those "faculties" in the above list, in which there was any thing but a coincidence to be noticed. It is idle to tell us that in three or four or half a dozen instances the organs were such as might be expected in a man like Dean Swift. When five or six and thirty guesses are made, it would be wonderful indeed if some of them did not happen to be right. Let us see, however, how some of the most remarkable "harmonize with the phrenological philosophy."

"Amativeness, large." Was the Dean amative at all? Hear Sir Walter Scott, to whose excellent life of Swift

we appeal the more willingly, as our phrenologist pretends to quote the work also, but, as we think, not fairly.

"His whole intercourse with Stella and Vanessa indicates the very reverse of an ardent or licentious imagination; and proves his coldness to have been constitutionally inherent, both in mind and person. * * * * The coarse images and descriptions with which Swift has dishonoured his pages, are of a nature directly opposite to the loose impurities by which the voluptuary feeds his imagination. The latter courts the seductive images of licentious pleasure; but Swift has indulged in pictures of a very different class, and dwelt on physical impurities, calculated to disgust, and not to excite the fancy."

Whether Swift was *philoprogenitive* or not, we will not venture to dispute. But "love of approbation, very large;" this, we submit, is, as an indication of the man, totally erroneous. Sir Walter Scott, in summing up the character of Swift, says, there were three peculiarities for which he was remarkable—viz. his originality, his total indifference to fame, and the distinguished excellence which marked him in all his undertakings. As a literary man,—the proudest light in which he can be viewed, if we except his patriotism, and even of that he was not vain—"the careless mode (says Sir Walter) in which Swift suffered his works to get to the public, his refusing them the credit of his name, and his renouncing all connexion with the profits of literature, indicate his disdain of the character of a professional author."

"Benevolence, *small*." Not only so, but it appears that, phrenologically speaking, Swift was totally destitute of benevolence.

"Above the frontal protuberances (in the region of Benevolence) the bone was thickened, apparently by a deposition of bony matter on its inner surface—making the inner surface at that part on both sides flat in place of concave, and smoother than the other parts; which was the more remarkable as the other portions of the skull were rather thin."

So says the report in the *Phrenological* journal. But was there ever such gross blundering? What says Sir Walter—for we will speak "by the card:"—

"The Dean's real and discriminating charity aimed at a better reward than popular applause. Even in his latter years, when habits of economy had assumed the appearance of parsimony, they could not overcome his principle of benevolence." And, again, he was "charitable and benevolent to the extreme limits of a moderate revenue."

Need we support these statements by reference to particular facts? The whole biography of this eminently benevolent man is full of instances. We cannot and need not occupy our pages with them.

Again: "Ideality, small." We presume this includes the faculty of *imagination;* and if so, every man, woman, and child (excepting the phrenologists), must see the utter folly and absurdity of such a *development.* What, the author of Gulliver, the Tale of a Tub, the Battle of the Books, and so many other productions in which the fancy and the imagination are predominant—destitute of "ideality"! He of whom it was pronounced by one of the most illustrious of his cotemporaries, "*qu'il avoit l'esprit createur*"—he deficient of "ideality!" If we be told that we mistake the meaning of *ideality*, we must only bow with submission, and acknowledge the jargon of phrenology to be quite too deep for us.

"Wit, *small*." But do we not fatigue our readers by noticing such downright nonsense? If Swift had *small* wit—who possessed *any?* Where are we to look for his superior?

"Imitation," too—"large," in this most original of all authors!

"Language," also, "large," in one who seldom used any but his vernacular: who was never noted for his philology, and who, in fine, simply used his native tongue as a mere means to an end—a tool by which some desirable object was to be effected.

The intellectual faculties, moreover, "comparison" and "causality"—"moderate," in this the finest and most subtle reasoner that ever wrote a political or controversial essay! But we have done.

We now leave the phrenologists to digest their discoveries, wishing them joy of the fortunate hit they have made in Swift: but we recommend them to try once more to reconcile the glaring contradictions between the developments which they detected and the well-known character of their subject.

After all, it may happen—we are half persuaded (from what we know of former *small mistakes*) that it has happened—that they have failed in their quarry. Let us hope that it has not been Swift's skull that has been examined. Let us fervently trust that the remains of him who so sorely felt the pangs of indignation during his lifetime, and aspired to escape them in the grave, are still undisturbed.

"Rest, rest, perturbed spirit!"

KING'S COLLEGE.

Is is not true, as some of the newspapers have stated, that Dr. Paris has been appointed to the chair of Materia Medica at this school, vacant by the resignation of Dr. Bisset Hawkins. We confess we were surprised at the announcement that the place had been vacated and disposed of in such a marvellous hurry: we are glad that nothing of the kind has been done. Publicity and fair election should attend all such appointments. Dr. Paris is said to be a candidate.

MIDDLESEX HOSPITAL.

Strangulated Inguinal Hernia — Operation — Death — Post-mortem appearances.

John Smith, æt. 45, was admitted into the Middlesex Hospital, on Tuesday evening, September 8th, with an irreducible inguinal hernia on the left side. The taxis were employed, and the man placed in a warm bath, and a large injection administered. There were no symptoms of strangulation at this time, and the swelling became much softer. At four o'clock the following morning the man began to vomit and hiccough, which increased, and at seven o'clock Mr. Tuson was sent for; he found that the hernia could not be reduced, but at the same time that it was not tense, nor was there much pain in the abdomen.

The man stated that he had had the rupture for many years; that it had only been down since the following afternoon; and that the bowels had not been relieved for the last eight days. He was ordered a large injection of house medicines and castor oil; and a consultation called upon the case at nine o'clock, at which time it was found that the bowels had been freely opened by the injection, but what had passed was considered as the contents of the large intestines. The hernia was softer, and the man could bear the hand pressed upon the abdomen without feeling pain; the vomiting and hiccough, however, continued, and he had violent cramps, so as to draw up both the legs. He stated that he was very subject to the cramp; that the last time it was down he had them just the same. It was considered advisable to wait till the usual hour of visiting the hospital, and in the meantime he was ordered one drop of castor oil. At 12 o'clock a consultation was again held upon the case, and the operation recommended, but the patient would not consent to it being performed. From this time the symptoms increased, violent pain came on in the abdomen, and the pulse began to sink.

September 11th.—The man was extremely restless; the pulse weak; constant vomiting and hiccough. At one o'clock he consented to the operation being performed; and as it appeared the only, although shadow of a chance of relief, it was performed. Mr. Tuson found, upon opening the hernial sac, the intestines in a gangrenous state; a large quantity of serum was discharged, nearly half a pint. It was thought advisable not to return the intestine, but to relieve the stricture which

was at the external abdominal ring, and to open the intestine, so as to make an artificial anus. This was done, and the contents of the intestine discharged. The part strangulated was the lower portion of the cœcum, the edges of which were left out of the wound. The patient was placed in bed, and a dose of Tr. Opii given him, with a view to produce a little rest and allay the sickness.

10 o'clock P.M.—The man was somewhat better; the sickness, perhaps, a little less; hiccough continues very troublesome; complains of pain at the pit of the stomach. A small quantity of the contents of the intestines have been discharged through the wound.

Apply a mustard poultice to the upper part of the abdomen.

℞ Sodæ Carb. ʒss.; Acid tart., ℈j.; Aq. puræ, ℥iss. Capt. in act. efferv. omni hora.

℞ Cal. gr. ij.; Opii, gr. ss. alterna quaque hora.

12th, 10 o'clock A.M.—The sickness continues, and the hiccough; a little more pain in the abdomen; little or no discharge from the wound.

℞ Haust. Efferv. cum Tinct. Opii, ♏vj. 4tis horis.

1 o'clock P.M.—Vomiting just the same, with hiccough. As there has been little discharge from the intestine, a canula was introduced into the wound, and directed towards the ileum. When the contents of that intestine were freely discharged, a canula was left in the wound, and half a seidlitz powder was directed to be given every four hours.

10 o'clock P.M.—Much the same; very restless; vomiting and hiccough; the bowels are open through the canula.

℞ Cal. gr. ij.; Opii, gr. j. statim, et rep. cras mane.

13th, 10 o'clock A.M.—Passed a very restless night; vomiting and hiccough not relieved; complains of more pain at the pit of the stomach; compares it to a hard ball; has a great desire for ginger-beer, which the nurse was ordered to let him ha e; it remained in the stomach for a short time, and relieved the hiccough a little, but only for a short time; it was ordered to be repeated, with

℞ Hyoscyami, ♏xx.

1 o'clock P.M.—The man appears much the same. The pulse is much better than it was before the operation. The canula has slipped out of the wound; it was therefore introduced again, and the contents of the intestine discharged. The pain still continues at the pit of the stomach, but the mustard poultice appears to relieve it.

A little Sp. Ammonia and Ether was ordered to be applied to the part, and covered with the poultice.

10 o'clock P.M.—Much the same; still vomiting, and complains of much inconvenience from the hiccough.

Soda water, with 20 drops of Tr. Opii was ordered.

14th, 12 o'clock.—Passed another very bad night; symptoms just the same; complains of great heat and thirst, although the skin is cold and the tongue moist. severe pain at the pit of the stomach.

Apply six leeches, and foment the part with the decoction of poppies.

℞ Aq. Menth. v. ʒiss.; Tinct. Opii, ♏v.; Magnesia, gr. x.; Magnesiæ Sulph. ℈j. 4tis horis sumend. Eggs with brandy to be freely given.

10 o'clock P.M.—Much the same; pulse a little stronger; kept some of the brandy and egg upon the stomach. Fæculent matter is still being discharged through the canula in the wound.

15th.—Passed a very bad night; restless; vomiting and hiccough; complains of much pain in the course of the inguinal canal; pulse weak and irregular. Still the same pain at the pit of the stomach.

Apply a blister to the part.

℞ Pil. Hyd. gr. iij.; Opii, gr. ss. 6tis horis sumend.

8 o'clock P.M.—Very restless. The canula has slipped out of the wound; it was introduced again, and a small quantity of fæculent matter discharged.

16th.—Passed a very restless night; pulse weak; skin cold, particularly the feet and hands; vomiting and hiccough continues.

A little lime-water was ordered, likewise the egg and brandy to be continued.

12 o'clock.—Complains of much pain in the course of the inguinal canal, and the part is much inflamed; a small quantity of the contents of the intestines pass by the wound.

The part was ordered to be fomented.

4 o'clock P.M.—He was much worse, the pulse sinking; he complains that he cannot move his arms or legs, which were found to be paralysed. The sickness, the pain, and hiccough, the same. From this time he gradually sunk, and died the fol-

lowing morning at 1 o'clock, being nearly one week after the operation.

Post-mortem examination, 12 hours after death.—Upon opening the abdomen no unusual appearances presented. The peritoneum was not inflamed; but upon tracing the small intestines at various parts of the jejunum, the vessels were in a state of congestion, almost approaching to inflammation. Upon dilating the wound it was found that the lower part of the colon, just above where the cæcum had been opening, the intestine had become in a gangrenous state, and that nearly half the circumference of the colon had sloughed to the extent of an inch and a half, and also the anterior part of the inguinal canal; at the same time there was no strangulation, the intestine being perfectly free. The brain was next examined. Upon removing the dura mater some fluid was found under the arachnoid membrane; and upon opening the lateral ventricles there was some fluid found, but not any great quantity; but at the base of the brain, and running down the spinal canal, a considerable quantity of serum was discovered, which might account for the palsy before death.

GENERAL LYING-IN HOSPITAL.

MIDWIFERY REPORTS.

By Edward Rigby, M.D. F.L.S. &c.

[Concluded from page 95.]

Attack of Milk Fever.

The next is a smart case of fever preceding the appearance of the milk, in a very irritable nervous subject:—

Oct. 25th, 1834.—Ann Barber, æt. 25, delivered of a boy; first child; first position. She is a short delicate looking woman, and during her labour never ceased from the expression of suffering by an incessant nervous whining, although the duration of her labour was but twelve hours, and its progress regular and equable. Twenty-four hours after delivery a very smart attack of fever set in, commencing with shivering, heat, and sweating; this paroxysm lasted three hours, at the end of which time she was hot and dry. Pulse very quick; eyes suffused and red; headache, tongue furred, and thirst.

℞ Hyd. Submur. gr. vj.; Pulv. Antim. gr. iv. statim. Cataplasma abdom.

10 p.m.—Bowels have been freely open; skin has a tendency to become moist.

27th, 5 a.m.—No sleep; is now in a high state of feverish excitement; the skin is burning hot; pulse bounds against the finger, 120 in a minute; great restlessness. Tongue white; thirst; much headache; bowels have been repeatedly purged; dejections watery and light-coloured.

℞ Liq. Ammon. Acet. ℥ss.; Vin. Antim. Tart. ♏xxv.; Træ. Hyosc. ʒss.; Mist. Camph. ℥vj. M. statim et secundâ quâque horâ.

Noon.—There is now a slight remission of the fever, but is very restless; occasionally dozes for a few minutes, but has not had regular sleep since her confinement. The bowels continue to be purged.

4 p.m.—The fever has increased considerably; pulse 120, hard and full; countenance very anxious; features sharp; lips pale and glazed; great headache; skin hot and dry. She was bled to ℥xvj. while reclining in bed; became faint, and the pulse diminished in force.

℞ Liq. Ammon. Acet. ʒiij.; Vin. Antim. Tart. ♏xl.; Aq. ℥ss. M. statim.

Vespere.—Secretion of milk has commenced; she had a copious bilious dejection directly after the bleeding, and again in an hour. The pulse is softer, and not so frequent; skin cooler; tongue moist.

Repeat the mixture, with Sp. Ætheris Nit. ʒss.

28th, 8 a.m.—Has had four hours' sleep, by which she is refreshed; has been perspiring. Skin now soft and cool; tongue moist; pulse slower. Her bowels have been purged every quarter of an hour whilst awake; the motions are scanty, and chiefly mucus. The mixture makes her sick.

Omit it, and let her have an enema of starch, with Træ. Opii, ♏xl.

Blood cupped and buffy.

Noon.—Bowels more quiet.

℞ Pulv. Ipecac. Comp. gr. v.; Hyd. c. Cretâ, gr. iv. tertiâ quâque horâ.

6 p.m.—Is perspiring copiously; had another dejection, for which the enema was repeated. The secretion of milk is now copious.

29th.—Has had a comfortable night; skin is moist; tongue cleaner; pulse soft; bowels not again open.

Noon.—She awoke suddenly from her sleep, much frightened about her child, which she had been dreaming was burned; is much agitated; eyes staring; feels low; mutters to herself. ℥ss. of castor oil produced a free motion.

Vespere.—℞ Camphoræ, gr. iij.; Ext. Hyosc. gr. v. Sago and wine for supper.

30th.—Has had four or five hours of comfortable and sound sleep; eat her breakfast heartily.

31st.—Continues to improve.

Peritoneal and Puerperal Fever.

There have been one or two cases of what the late Dr. Gooch would have termed peritoneal fever; and towards the end of the year, of puerperal fever, some of which recovered, but two have proved fatal. I have little or nothing satisfactory to offer on this subject; there is no lack of recorded cases, and I should be only occupying your pages to no purpose. The morbid anatomy of puerperal fever has been successfully investigated by the researches of medical men in this country and in France. I wish I could say as much in favour of its pathology. Scarcely any cases of uterine phlebitis have occurred during the last two years, although till then it was by far the most common—in fact, I might almost say the only—form of puerperal fever which existed in and about the metropolis.

The following case is interesting, because, upon the first sight, it would appear to have been an attack of phlegmasia dolens; further investigation, however, will shew that it was something very different. The case is also interesting because it occurred in a female remarkable for extreme spinal deformity.

Phlegmasia Dolens—Complicated—Morbid Anatomy.

Nov. 6th, 1834.—M. A. P. M., æt. 34, (single), delivered of a girl; first child. Labour natural and regular; first position. This woman has a very prominent lateral curvature of the spinal column, tending to the left side; it occupies principally the dorsal portion of the spine; the pelvis is ample and well formed.

On the following day (7th) had two shivering fits, followed by heat and sweating; the pulse quick; complains of some abdominal pain, and also pain of the chest. There is cough, but has no difficulty of breathing, or stitch. The pain appears to be in the parietes, from constantly lying in one position (on her right side) in consequence of the spinal curvature. A powder consisting of calomel, gr. v., pulv. antim. gr. iv. was given immediately, which acted freely on the skin towards evening. The bowels had not been open; she had headache and was restless, and therefore in the night took mist. senna, ℥iss.

8th.—Bowels have been open three times; continues to perspire; has some pain of the abdomen on pressure, but does not complain of it unless particular inquiry is made. She sleeps much. Dr. Rigby saw her, and advised a mixture of carbonate and sulphate of magnesia in peppermint water, of which she took two doses. The bowels were purged twice by this means, and it was stopped.

9th.—This morning she looks very anxious; the eyes are staring; brows corrugated; very restless; frequently changing her posture in bed. Pulse is quick and small; tongue furred and dry; skin hot but moist; bowels continue to be purged; the dejections watery, bilious, and offensive. Slight lochial discharge has commenced this morning, and the breasts have begun to secrete. The abdominal pain continues, but it is of a very slight and uncertain character.

A hot poultice was ordered to be applied, and Camphoræ, gr. iij.; Extr. Hyosc. gr. v. statim.

In four hours after taking the pill she fancied there were people about the bed. Pupils natural; pulse quick; perspiration constant; cough troublesome. In the evening the lochia ceased.

℞ Liq. Ammon. Acet. ℥iij.; Træ. Camph. Comp., Sp. Ætheris Nit. aa. ℥ss.; Aq. Anethi, ℥vj. quartâ quâque horâ. The pill to be repeated at night. The vagina to be washed out with warm water.

10th.—Has slept twice, for a couple of hours each time; looks less anxious. Pulse not so quick or small; bowels still relaxed. She talks foolishly, but in a coherent manner.

Cont. Mistura, et nocte repet. Pil. Camph. et Hyosc. Sago and wine.

11th.—Appearance improved this morning; pulse quick and soft; tongue clean; perspiration free, but very fœtid. Has had one watery motion in the night.

℞ Camph. gr. ij.; Ext. Hyosc. gr. iij. secundâ quâque horâ. Beef-tea for dinner.

Vespere.—She is better.

12th.—She was much improved in her appearance last night, but has not had any sleep, and this morning has a very pale anxious countenance. Has been purged six times, and this morning has two or three times vomited glairy mucus, containing a fluid like coffee-grounds. She has now great pain in the uterus, increased by pressure. Pulse small and quick; skin warm; tongue moist, and of a natural colour. Two grains of opium were

given to check the vomiting; arrow-root and brandy. At half-past 9 she was seen by Dr. Rigby, who prescribed effervescing draughts, with five grains excess of carb. ammoniæ, to be repeated whenever the vomiting occurred. At 11 vomited again, and the draught was repeated, with the addition of ♏xxx. of tinct. opii. In half an hour afterwards she complained of sudden acute pain about the umbilicus, which has become slightly tympanitic. The parietes are so thin that the contents may be traced; the pain is increased on the slightest touch; she does not now complain of any pain of the uterus. A mustard cataplasm was applied over the painful spot for half an hour; inflammation of the skin was thus excited, and the pain removed. At 2 P.M. passed a coagulum from the uterus the size of a walnut; has vomited two or three times. She was removed to a fresh bed in a separate room, and two grains of opium were given.

4 P.M.—Stomach has been quiet for two hours; vomiting was then renewed by drinking some tea. The presence of fluids appears to excite vomiting; jelly was therefore obtained for her, and she kept it upon her stomach.

10 P.M.—Has not vomited for six hours, and is more comfortable. Took a glass of port wine, with bread sopped in it, and had sago with wine to take during the night.

13th.—Has slept well, and is much better this morning; she has lost the offensive odour; lochia are in good quantity, and of natural appearance. Pulse good; skin warm. She had a mutton chop for dinner this day; the eyes have a bilious hue; tongue rather dry; has had four watery offensive motions.

℞ Hyd. c. Cretâ, gr. iv.; Pulv. Ipecac. C. gr. x.

14th.—Has been remarkably well since last report; towards evening she became irritable about trifling matters. Had a mutton chop for her dinner, but complained of feeling exhausted after eating it, and she vomited after taking some table beer which she had begged for; no pain.

To have arrow-root for supper.

15th.—Had a very good night, but looks anxious to-day, and refused animal food. Complains of pain at the outside of the left thigh, extending from the ilium to the knee, very exactly in the course of the inguino-cutaneous nerve. It is tender to the touch. There is *no pain* on pressing the femoral vein at the groin. Towards evening the pain of the thigh became more severe, and slight swelling is now perceptible.

To be rubbed with anodyne liniment.

16th.—Has had no sleep last night; she looks extremely anxious; her eyes are sunken, face pale, and features sharp; pulse small; has again some diarrhœa; complains greatly of the pain at the outside of her thigh; it is very tender, and more swollen. The femoral vein was again carefully examined, but still there is no pain on pressing this vessel.

℞ Camph. gr. iij.; Ext. Hyosc. gr. v. statim.

At 12 she was seen by Dr. Rigby, and by his request had

Quinini Sulph. gr. j.; Acid. Sulph. Dis. ♏x. tertiâ quâque horâ. Hyd. c. Cretâ, gr. iij.; Sodæ Carb. gr. v., and nourishment.

At 3 she was seen by Dr. Ley, who from the appearance of the thigh judges it necessary to have leeches and hot fomentations applied.

The Hyd c. Cretâ to be repeated, and the other medicines to be omitted.

Sixteen leeches were applied, and followed by hot fomentations and poultices. Immediately after their application she became so low that it was necessary to administer brandy to prevent syncope. At 3 the next morning her powers had greatly failed. Brandy and laudanum were given, and repeated at intervals, with other cordials; but she sunk rapidly, and died at noon.

Post-mortem Examination.—Body much attenuated; left thigh one-third greater in circumference than the right; abdomen tympanitic, not tense; parietes very thin; the lower part of the ileum, caput coli, and arch of the colon, contain air: a streak of inflammation is delineated along the anterior surface of the colon from the centre of the arch, throughout the descending portion of this intestine, to the left iliac region; it is marked by a transverse band of capillary vessels minutely injected in the thickened peritoneum along the whole of this course. A few convolutions of the small intestines were smeared with recent lymph, and one fold was found to adhere closely to the left side of the pelvic peritoneum, at the point of reflection of the ligamentum latum uteri. A few small portions of coagulable lymph were also found loose amongst the intestines. At the posterior surface, and left side of the body of the uterus, soft lymph and pus were effused for the space of an

inch beneath the peritoneal covering of this viscus, the membrane itself being highly vascular from inflammation, but still showing the effusion through its texture; the fundus of the uterus, where it has the fallopian tube and round ligament attached, was similarly affected, though in a slighter degree; lymph and pus were effused here also. From these two points the inflammation appears to have spread to the rest of the serous membrane; from the first indicated point it has progressed along the posterior fold of the broad ligament to the surface of the rectum and colon; from the second situation the round ligament and fallopian tube have formed the continuous line of its progress. On raising the peritoneum from the iliac fossa, the cellular membrane which envelopes the round ligament where this cord is about to pass under the epigastric vessels, after quitting the peritoneal cavity, was found infiltrated and condensed with lymph and pus. The whole of this cellular membrane (which it will be borne in mind is the fascia propria of Sir A. Cooper, and which fills the *femoral* ring, and moreover forms the medium of transmission for the lympathics of the thigh) was in the same condition, densely matted by lymph, and containing pus in the interstices*. The lymphatic glands in the groin were slightly enlarged, and some serous fluid was effused into the surrounding tissue; the femoral vein and artery were free from disease; the inner coat of the former vessel, as well as the external and internal iliac veins, and vena cava, had not the slightest trace of increased vascularity or thickening; the chain of glands from the femoral ring along the course of the iliac vessels and aorta *on the left side* were enlarged, soft, and vascular; several of these lymphatic bodies contained between the layers of the meso-colon, were found enlarged, and to contain soft lymph. The uterus was of the size usually found at this period; its tissue dense; the section shows the sinuses still large; the openings on the internal surface plainly indicated by adherent coagula. The curvature of the spine is the lateral, and takes in the whole of the column, from the first dorsal to the last lumbar vertebra; the two uppermost vertebræ have a slight tendency to the right side; a sudden turn is then made to the left, and there results a very acute angle at the centre of the dorsal portion in the left side of the thorax: from this to the sacrum the column is gradually regaining its proper direction; the ribs are much distorted, and the left side of the thorax is greatly encroached upon: the pelvis ample in every direction. The post-mortem examination was made with the greatest care by my friend Mr. Nordblad, to whom I am also indebted for the report of the case. The entire absence of inflammation in the veins is an interesting fact, and shows that phlegmasia dolens may exist to a considerable extent from inflammation of the above-mentioned portion of fascia, thus rendering impervious the large lymphatic trunks which pass through it. This cannot, however, be looked upon as a pure case of phlegmasia dolens: the situation of the pain on the *outside* of the thigh, and absence of pain in the course of the femoral veins, the absence of venous inflammation upon examination after death, the peculiarly purulent sloughy state of the cellular membrane in the groin, the effusion of puriform fluid and lymph in the abdomen, the rapid sinking after the application of leeches, shows that it partook in great measure of that malignant form of puerperal fever which is accompanied with sloughing of the cellular tissue, and formation of large collections of ill-conditioned pus in different parts. From the entire absence of pain in the course of the femoral vessels, I had ventured to overlook the local affection for a time, and direct my attention entirely to the state of the general system, and rouse its powers to a better and more healthy action; how far I was right in doing so under the existing circumstances may perhaps be a question; the pain, however, had in three hours increased so much that my excellent colleague considered it necessary, at all events, to hazard local depletion, but the powers of the system proved unequal to the demand.

Double Pregnancy.

Another case of doubtful pregnancy occurred during 1834, but the error was detected before she came into the hospital: the time gradually passed away; no labour appeared, and examination was requested, to ascertain her real condition.

May 28th, 1834.—Anne Ireland, a well-formed but unhealthy-looking woman, received an in-door admission on the 10th of March, expecting soon to be confined; has gone on to menstruate regularly during the whole time she has supposed herself pregnant, and has suffered much from dyspepsia, and bearing-down pain whenever she walks: for the last three months has felt lancinating pains shooting through the groin and sacrum, coming on without any evident cause; has had difficulty in retaining her water for any length of time

* This condition of parts bore the closest analogy to the state of the cellular membrane so constantly observed in fatal cases of phlegmonoid erysipelas, or diffuse cellular inflammation.

for the last three years; much pain is produced in passing solid fæces, but liquid dejections pass easily; abdomen is swelled, especially to the right side; there seem to be irregular masses of tumor, some harder than others, arising out of the right iliac fossa, where she first observed the swelling; the whole abdomen elastic; no fluctuation, and not peculiarly painful.

On examination per vaginam the cervix uteri is about three-quarters of an inch long, rather hard, and low in the pelvis, the os uteri forming a transverse fissure; the lips are too close to admit the finger; her bowels at times have been much deranged, and occasionally she has passed a quantity of blood per rectum, without relief or diminution of size: active purging was tried for a short time without benefit; she went to the sea-side, and I lost sight of her.

This was, in all probability, a case of ovarian disease, the swelling having commenced on the right side. The uterus itself, as far as the finger could reach, being quite natural and merely prolapsed, lead one to this conclusion: the difficulty in passing solid fæces, and inability to bear much urine in the bladder, show the existence of a large and heavy mass at the brim at the pelvis; the feel of the abdomen externally confirms this. I did not see her long enough to form any decided opinion.

Pemphigus Infantilis.

During the last year a disease has prevailed, to a considerable extent, among the children born in the hospital, which is otherwise of rather rare occurrence, viz. the pemphigus infantilis, appearing on different parts of the body, particularly the extremities and neck, in minute vesicles, which gradually increase into bullæ, and which burst, leaving a raw discharging surface: the ichorous fluid which is secreted inoculates the surrounding parts, and this keeps up the disease for some time. Generally speaking, the children have recovered from it, but in two or three it has spread to a great extent, and produced such constitutional irritation as proved fatal. In the following instance it showed itself peculiarly severe, and I requested Mr. D. Dalrymple to draw up a report, in order to give a view of the general character of the disease.

"May 29th, 1834.—Mrs. Martyn's child. About four days after delivery the vesicles first made their appearance on the neck, breast, and arms, of the child, accompanied with a green slimy discharge from the bowels; the mother suffered severely from inflamed nipples, which entirely prevented her from suckling the child.

June 1st.—Thirteen days after birth the child presented the following appearance: the nose, lips, and chin, were one raw surface; the hands and arms were entirely denuded of cuticle, except just in the palms of the hands and tips of the fingers; the scrotum, inside of the thighs, nates, and back, were studded all over with vesicles: the skin of the breast and belly presented a curious appearance, from the veins being very numerous and prominent, and crossing each other in every direction; the mouth and fauces were in an aphthous state; the child dwindled to a skeleton, and capable of retaining nothing in its stomach: no topical applications seemed to produce the slightest effect: hyd. c. creta c. sodæ carb. were given internally, but remedies proved unavailing, and on the evening of the following day it died. The body was examined about twenty hours after death. The mucous membrane of the œsophagus, from the thyroid cartilage to the cardiac extremity of the stomach, was studded with aphthous spots; the stomach was in a very inflamed state, presenting patches varying in colour from bright red to dark brown, and patches also of effused lymph; the duodenum was also inflamed, but in a less degree, and presented a few specks of ulceration: the rest of the intestinal canal showed but few spots of inflammation, and the villous coat was but little altered from its natural appearance. The left lobe of the lungs was much gorged with blood, and did not crepitate freely, the rest of the viscera were in a natural condition. The head was not allowed to be opened. This disease was not confined to the children only, but some of the mothers had many spots, Mrs. Martyn in particular, and in a few days after the post-mortem examination, during which I pricked myself, several spots made their appearance on my face and chest, which were some days before they healed, and to the pain and irritation which they excited I can testify."

Morbus Cæruleus.

The following case of morbus cæruleus is interesting, because it did not depend on a previous state of the foramen ovale in the inter-auricular septum, but of the ductus arteriosus:—

Jane Stanway's child, (boy) born Oct. 23rd, 1834.—This child was a few minutes before it obtained free respiration, or contracted the muscles, but it cried and also sneezed vigorously before the funis was tied; it was laid before the fire for some time previous to washing and dressing, and appeared to have fully established the respiratory function. About four hours after birth it was observed to moan constantly, and appeared in a comatose condition; the surface especially of the face and the nails was discoloured, and the temperature diminished; the motions are

very feeble; it refuses to take the breast; occasionally the discolouration increases, accompanied with contraction of the features and an expression of increased distress; the action of the heart is very feeble; the respiration hurried; frothy mucus or saliva constantly passing from the mouth; the eye-lids closed: an injection was immediately administered, which quickly brought away a good deal of meconium, and a teaspoonful of castor oil was given, which it swallowed, as also a few teaspoonfuls of gruel, with much difficulty.

24th.—Has continued in the same condition during the night, constantly moaning feebly, lying motionless and refusing to take the breast; the bowels have been opened freely by the castor oil. It was put into a warm-bath; whilst in the water it became more discoloured, apparently accompanied with great distress; the bowels pretty freely opened; dejections pale; liver does not seem to be secreting; five drops of sp. ammon. fœtid. in gruel, to be thrown up the rectum, and to have hyd. c. creta, gr. ij.; sodæ carb. gr. j. It continued in the same condition during the day; towards the evening some slight spasmodic twitches of the trunk and extremities came on, evidently producing much distress. It was immediately put into the warm-bath for ten minutes: the body below the axillæ is now of a death-like paleness; the face, and especially the lips, blue, cold, and soft, very closely resembling the external characters of cholera asphyxia.

25th.—Is much more feeble; pulsation of the heart scarcely perceptible; inspiration at long intervals; surface cooling; 11 A.M. died.

Post-mortem Examination.—A small quantity of bloody fluid was contained in the pericardium; both auricles filled with black blood; the right cavities tensely distended; the foramen ovale perfectly closed by the valve of the interauricular septum, through which the contents of the left auricle were seen of the same hue as the venous blood. The ductus arteriosus was still a pervious canal; the umbilical vein was found contracted, and containing a small *adhering* coagulum; the ventricles natural; the ascending portion and arch of the aorta of proper dimensions and structure, but at the point where this vessel becomes the descending aorta, and precisely where it received the ductus arteriosus, the canal was not larger than the calibre of a crow's quill; the system of vena portæ and umbilical vein were perfectly normal." For the report and highly interesting dissection of this case I am indebted to my friend Mr. Nordblad.

ON THE EFFECTS OF POISONS ON THE ANIMAL SYSTEM.

A REPORT from Dr. Roupell was read at the Dublin Meeting of the British Association, the object of which was to shew the effects produced by poisons introduced into the circulatory system, and the affinity they appear to exercise for the component elements of different parts of the body. Several plates were exhibited, illustrating the results.

Plate 1 represented the stomach and intestinal canal of a dog, poisoned by *arsenic*. An ounce of the saturated solution of arsenic, made by boiling arsenious acid, and allowing it to cool, was injected into the femoral vein of a dog. In three minutes afterwards, the animal became sick, and made an attempt to vomit; his breathing also became very much hurried. In ten minutes more, great intestinal movements appeared to be going on, and the abdominal muscles were forcibly contracted; in twenty-five, vomiting took place, followed by paralysis of the hind legs; in thirty-five the animal died. The body, when examined shortly afterwards, was found rigid, the blood fluid, the lungs stuffed with mucus, but not inflamed. The peritoneum was rough, and had lost its shining appearance; the stomach presented the hour-glass contraction, and was found to contain an ounce of tough mucus. The great end was much inflamed, the lesser differed very little from its healthy state. The large intestine was free from disease, and contained solid fæcal matter. The chief alteration was in the small intestine, which was extensively inflamed, and covered with a layer of tough mucus, tinged with blood. There was no change in the mucous membrane of the trachea or bronchi; or in the lining of the heart, veins, or arteries. The chief points of interest connected with this experiment are the absence of inflammation in those parts with which the poison came in contact, and the circumstance of its being restricted, almost exclusively, to the intestinal canal.

Plate 2 represented the stomach of another dog, poisoned in the same way. The subject of this experiment was a strong animal, and the solution of arsenic which was employed had been filtered. The same quantity, however, was administered as in the former case, and the poison was injected into the femoral vein. Shortly after the operation, vomiting took place; in twelve minutes solid fæces were passed from the bowels, followed by tenesmus. In thirty-five minutes, vomiting, cramps,

and dysenteric symptoms, occurred, which continued with more or less severity, and in about two hours the animal died. The lungs were injected, but not inflamed. The stomach and intestines were universally inflamed; the former contained about four ounces of frothy mucus, the latter, throughout its entire length, a bloody secretion. The mucous membranes of the rest of the body were redder than natural, but no change could be detected in the lining membrane of the venous or arterial systems. In this instance, the longer interval between the injection of the poison and the death of the animal gave time for a greater extension of inflammation.

Several experiments were made with smaller quantities of the arsenical solution, but without any fatal result. Half an ounce, thrown into the femoral vein of a strong dog, appeared to produce but little inconvenience. Half an ounce of the *liquor hydrargyri oxymuriatis* was injected into the veins without producing any appreciable result. An ounce (which contains half a grain of the corrosive sublimate) produced dysentery and considerable distress, but not death.

The next trials were made with *tartar emetic;* the preparation employed was the vinum antimonialis. An ounce of this was thrown into the saphena vein of an active terrier. The first and almost immediate effect of this was to produce symptoms resembling intoxication,—a circumstance which may be attributed to the quantity of alcohol contained in the preparation employed. The animal was able to stand and run, but reeled about and tottered in his gait. On being visited some hours afterwards, it was found dead; from the appearance of its jaws, vomiting seemed to have taken place. The brain was found natural in appearance, and the intestinal canal presented nothing different from the normal state; the chief alteration appeared to have occurred in the stomach, which exhibited signs of intense vascularity, particularly at its greater end.

Several other experiments were made, but of less interest: when a solution of a metal in strong acid was employed for the purposes of injection, death took place rapidly, and the mucous membrane presented a marked red appearance. Dr. Roupell had been able to satisfy himself as to how far such changes in the intestinal canal are to be attributed to the compound, or to the effect of the simple acid, which in itself would coagulate the blood, or greatly predispose to that condition. The injection of a solution of *kreosote*, a substance which appears to possess the greatest power in this way, has no influence on the intestinal canal A drachm of this substance, mixed with water, produces no effect; but when injected pure, death has been the result. The appearances seen on dissection in this case, were confined to the lungs, which were black and gorged with blood that appeared to consist of minute granules, mixed with a fluid of inky blackness.

Dr. Roupell concludes, that any attempts at explaining the effects of the foregoing experiments, must, in the present state of animal chemistry, be merely conjectural. How far poisonous substances prove irritant by their chemical agency, or by exciting in certain parts the peculiar susceptibility to inflammatory action, it is not easy to determine, but it must be admitted that something more than mere contact is required in those cases where irritants applied to the surface, or thrown into the veins, provoke inflammation of the intestinal canal. Whether it be, that the system is on its guard against those substances which tend to increase the coagulation of blood, must be made a matter for future investigation; but certain it is, that substances endowed with this property seem to have a great tendency to excite the inflammatory condition. It is a curious fact also, as connected with this point, that the coagulation of the blood becomes diminished under such circumstances, or in other words, that coagulation goes on more slowly in an inflamed state of the blood*.

QUACKERY IN FRANCE.

One Gardereau, a peasant of the Indre et-Loire, having been confined to his bed for six months, was induced by a neighbour to apply to a quack of the name of Gautier. On visiting his patient, the quack doctor announced that poison had done the mischief, but that he had a cure: he required, however, 11 francs to begin with, in order to propitiate the Evil one. Next day another visit was paid, when Gautier, having examined the urine, and made sundry grimaces, mentioned a remedy which would cost 30 francs a quart. The money was paid, and the potion delivered. It consisted of a many-coloured powder dissolved in a large quantity of water; on taking which the patient expired in excruciating agonies. Gautier was prosecuted, convicted of obtaining money under false pretences, and sentenced to imprisonment for five years. He appealed to the Court of Tours, where he pleaded his own cause, and stated that he was a horse-doctor: he had found, he said, the Caryophillata in a book of veterinary prescriptions, and he thought it would be good for

* Dublin Journal of Med. Science, Sept. 1835.

Gardereau. He produced in court a book of magic, in which he pretended to be an adept. The book was entitled *Enchiridion Leonis Papæ Serenissimo Imperatori Carolo Magno in munus datum*, professing to have been written by Leo the Third in the ninth century. Many curious recipes are contained in the work—such as for winning at play, escaping the conscription, discovering a thief, &c.: but Gautier found none in it to save him from the jail. The court confirmed his sentence.—*French Papers.*

FOWLS CLOVEN ALIVE—

AN OLD REMEDY *IN EXTREMIS.*

The *Essex Herald* tells us of a deed of "superstition and cruelty" just perpetrated in its neighbourhood. "A young man, not far from this town (Chelmsford) was last week in the agonies of death, when his father was induced to try the powers of a potent spell, which he was assured would restore the dying man to health and vigour. He accordingly procured a live pigeon, split it suddenly down the middle of the body with a sharp knife, and applied the severed parts, still moving with life, to the soles of the feet of the dying patient, fully expecting to behold its instantaneous effect. The son, however, was a corpse a short time after." About two centuries ago the "superstitious and cruel" remedy here mentioned would have been looked upon as a matter of course. It was one of the many methods tried in the last illness of Prince Henry, the son of James the First. "A cock cloven by the back" was applied to the soles of the Prince's feet, with the consent and advice of the eminent medical men—among them Mayerne, Butler, and Hammond—who had charge of the case. But it does not appear that any benefit was derived from it; the royal patient died on the second day after.

WESTERN DISPENSARY.

Dr. R. B. Todd has been elected Physician to the Western Dispensary, in the room of Dr. Clendinning, Physician to the Marylebone Infirmary, resigned.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

October 22d, 1835.

William Henry Cufaude, Norwich.
Charles Kingford Vacy, Cornwall.
William Simpson Lambert, Sunk Island.
John Spurrier, Northumberland.
John Griffin, Deddington, Oxfordshire.
George Gibson, Ulverstone.
George Parker, Upton House, Gloucestershire.
John Taylerson, Whitby.
James Tunstall, London.

NEW MEDICAL WORKS.

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By Jon. Pereira, Esq., F.L.S.

Lecture V.

COUNTER-IRRITATION.

I propose in this lecture to examine that mode or principle of cure usually denominated *Counter-irritation*, and which consists in exciting an artificial or secondary disease, with the view of relieving a primary one. It is a method of treatment derived from observation of the influence which maladies mutually exert over each other. For example, it has been frequently noticed, if a diarrhœa come on during the progress of some internal diseases, the latter are often ameliorated, or perhaps they rapidly disappear, apparently in consequence of this secondary affection. The result of observations of this kind would naturally be the employment of alvine evacuants in other analogous cases where diarrhœa did not spontaneously take place: and this practice is frequently attended with beneficial results. The appearance of a cutaneous eruption is sometimes a signal for the disappearance of an internal affection; and *vice versâ*, the disappearance of a cutaneous disease is sometimes followed by disorder of internal organs. Here, again, we have another remedy suggested, namely, the production of an artificial disease of the skin, as by blisters, an ointment containing tartar emetic, or other irritant applications;—a suggestion the advantage of which experience has frequently verified. I might bring forward numerous other examples to prove the fact (which, however, is so well known as to require little proof), that action in one part will often cease in consequence of action taking place in another. Diseases, then, appear to have what Dr. Pring calls a *curative relation* with respect to each other; and we shall find that the greater part of our most valuable and certain remedies operate on the principle of counter-irritation; that is, they produce a secondary disease which is related to the primary one. Let us offer a few examples: — vomiting is a powerful means of relief in bubo, and also in swelled testicle. Mr. John Hunter says he has seen bubo cured by a vomit. I have frequently seen the progress of swelled testicle in gonorrhœa stopped by the exhibition of full doses of tartar emetic. Now it is very improbable that the benefit arises from the mere evacuation of the contents of the stomach. The only plausible explanation that we can offer is, that the emetic sets up a new action in the system which is incompatible with that going on in the groin or the testicle. If this notion be correct, emetics act in these cases as counter-irritants. The efficacy of purgatives, in affections of the head, is best accounted for by supposing that they act on the principle of counter-irritation. Blisters, cauteries, issues, moxa, and other remedies of this kind, are universally admitted to have a similar mode of operation.

Even the efficacy of bloodletting, in inflammatory affections, is better explained by assuming that this agent induces some new action incompatible with the morbid action, than that it is merely a debilitant. The immediate effect sometimes produced on disease, by this remedy, is so remarkable as hardly to admit of the supposition of its acting as a mere weakening agent. One

full bloodletting will sometimes put an immediate stop to ophthalmia; and I have sometimes seen, even while the blood was flowing, the vascularity of the eye diminish, and from that time the disease progressively declined. When to this fact we add that the same disease is often successfully treated by other different, and even opposite remedies, such as mercury, and local stimulant applications, we find a difficulty in explaining their common beneficial agency, except by supposing that they influence disease by some relation common to all of them. This view of the counter-irritant operation of bloodletting is supported by Dr. Clutterbuck, Dr. Pring, and others. The term *counter-irritant* is, however, objectionable, since literally it expresses that the secondary disease should be a state of irritation,—a term hardly applicable to the condition caused by bloodletting. But this, as well as other remedial agents (mental impressions, for example), agrees with the counter-irritants, commonly so called (blisters, &c.), in influencing diseases only by an indirect relation; it would be better, therefore, either to extend the meaning of the term counter-irritant, or to employ some other, such as *counter-morbific*. The older writers employed two terms, *revulsion* and *derivation*; the first was applied to those cases in which the secondary disease occurred in a part remote from the seat of the primary affection; the second was, on the contrary, confined to those instances in which the secondary was produced in the neighbourhood of the primary disease. For example, leeches or blisters applied to the feet in apoplexy were called revulsives, but the same applications to the head, in the same disease, would be derivatives. There is, however, no real distinction between them, their operation being similar, for revulsion was even in their own sense of the word only derivation at a distant part.

Topical applications are frequently counter-irritants. Thus we see stimulant washes, applied to the eye, cure ophthalmia; and they operate, apparently, by altering the morbid action, and substituting a milder and more easily cured disease for the one previously existing.

Using the term, therefore, in its most extended sense, we see our list of counter-irritants is a most extensive one. It comprehends emetics, purgatives, diffusible stimulants, mercury, blisters, cauteries, issues, setons, moxa, bloodletting (including arteriotomy, venesection, cupping, and leeches), irritating lavements, frictions, sinapisms, rubefacients, the hot and cold baths, and even mental impressions. That is, all these agents excite some action in the system which has a relation (oftentimes beneficial) with the morbid action: to use Dr. Parry's words, these agents cure disease by *conversion*.

Let us, in the next place, examine that most unsatisfactory part of our subject, the theory or hypothesis of the manner in which the mutual relations of diseased actions are effected. Dr. Parry presumes most diseases consist in local determinations of blood, and that it is a law of the human constitution that excessive morbid determination to two different parts shall not exist in the same person at the same time. Neither of these assumptions, however, is quite correct; but if both were true, they still leave untouched the question how determination of blood to one organ is cured by producing a determination to another. To account for it, some assume that the system can produce only a certain quantity of nervous energy, and that, as in every disease, there is an undue or preternatural distribution of nervous energy, so the production of an artificial disease in one part must, by consuming the nervous energy, diminish the disease in another. But the whole hypothesis is grounded on assumptions perfectly gratuitous and incapable of proof. As Dr. Pring justly observes, were this hypothesis true, it would lead us to employ not bleeding, purgatives, blisters, and all indirect remedies in hepatitis or consumption, but the exercise of the tread-mill for a few hours; so that a patient labouring under phrenitis or pneumonia should be made to walk fifteen or twenty miles a-day, by which it would be presumed so much nervous energy would be consumed in the arms and legs, that there could not possibly be any preponderance or excess in any other seat.

Let us, then, discard absurd hypotheses of this kind; and for the present be content with a knowledge of the fact that one disease, whether artificially or spontaneously generated, will often supersede another. You may, if you please, say that the mutual relation of two diseases is effected by sympathy; but recollect that this mode of expression explains nothing, and gives no information as to the mode by which the relation it effected, —for the word sympathy is applied to those relations only, the causes of which are not understood.

OF THE PARTS TO WHICH MEDICINES ARE APPLIED.

As the effects of medicines vary according to the part of the body to which these agents are applied, and as in practice we are compelled frequently to vary the locality of our application, so it is necessary for

me to examine, in a general way, the peculiarities attending each place of application.

Medicines may be applied—1stly, to the common integument or skin; 2dly, to a mucous membrane; 3dly, to a serous membrane; 4thly, to wounds, ulcers, or abscesses; and 5thly, we may inject our remedial agents into the blood-vessels.

1st. *Of medicines applied to the common integument.* — Applications are frequently made to the skin in order to excite local effects, as in the case of blisters, cataplasms, fomentations, lotions, embrocations, &c.; and occasionally to affect remote parts of the system, as by the use of mercury. Most, if not all medicines, which influence distant organs by application to the skin, do so in consequence of their absorption; and as the cuticle offers a mechanical impediment to this process, we generally either make use of friction, or remove the epidermis in order to overcome this obstruction.

There are three methods of applying medicines to the skin, namely, the *enepidermic*, the *iatraleptic*, and the *endermic*.

(*a*). The *enepidermic method* consists in applying medicines to the skin, unassisted by friction; as when we employ plaisters, poultices, lotions, fomentations, baths, &c.

Gases or vapours are sometimes applied to the skin, either as local agents, or as means of affecting the constitution. Thus, baths of sulphurous acid gas are employed in itch; chlorine gas is recommended as an application to the skin in liver complaints; vapours of various mercurial preparations have been employed to effect salivation. The vapour of hot water, holding in solution the volatile matters of vegetables, has been employed in the treatment of many diseases, under the name of medicated vapour baths; though doubtless the greatest part of their efficacy is referrible to the influence of the hot aqueous vapour.

(*b*). The *iatraleptic method* (which has been so called from ἰατρευω, to cure or heal, and αλείφω, to anoint), consists in the application of medicines to the skin, aided by friction. It has been termed the *epidermic method*, — sometimes *anatripsologia* (from ἀνατρίβω, to rub in, and λογος, a discourse), and also *espnoïc medicine*. It was employed by Hippocrates and other old writers, but fell into disuse until attention was again drawn to it by Brera, Chiarenti, Chrestien, and others. Among the substances which have been employed in this way, I may mention camphor, digitalis, squills, cantharides, sulphate of quinia, veratria, colocynth, rhubarb, opium, belladonna, mercury, chloride of gold, &c. The doses of medicines require to be considerably larger than when these substances are given by the stomach: generally two or three, often as much as ten, and in some cases even twenty times the customary dose; but no absolute rule can be laid down. The objections to this plan of treatment are the uncertainty of results, the time required to put the system under the influence of medicines, the frequently unpleasant nature of the process (as when mercurial inunctions are employed), and the local irritation sometimes produced by the friction. Notwithstanding these, however, it may be resorted to occasionally with advantage, as where the patient cannot or will not swallow, or where the alimentary canal is very irritable or insensible to the action of the medicine.

(*c*). The *endermic* or *emplastro-endermic* method has been recently proposed by Lembert and Lesieur. It consists in the application of medicinal agents, incorporated with cerate or gelatine, to the cutis vera, the epidermis being previously removed by a blister or by heat. Morphia, quinia, nux vomica, musk, digitalis, sugar of lead, and many other agents, have been tried, and found to produce the same effects as when taken into the stomach. The operation is in general very quick, and in some cases more rapid than when the same substances are swallowed. If the gastric membrane be inflamed, or if the patient cannot or will not swallow, and the case be urgent, this is an admirable method of putting the system under the influence of a medicine. When it is desirable to produce speedy vesication, we may effect our purpose either by hot water or by a heated metallic plate.

2ndly. *Medicines applied to the mucous membranes.*—We have two mucous membranes to the different parts of each of which we make application of medicines: the first is the gastro-pulmonary membrane, the second the urino genital.

(*a*). *Gastro-pulmonary membrane.*

1. Ocular mucous membrane (conjunctiva).
2. Nasal or pituitary membrane.
3. Bucco-guttural membrane.
4. Eustachian membrane.
5. Aërian or tracheo-bronchial membrane.
6. Gastro-intestinal membrane.
7. Recto-colic membrane.

(*b*). *Urino-genital membrane.*

8. Urethro-vesical membrane.
9. Vagino-uterine membrane.

1. *Ocular mucous membrane* or *conjunctiva*. —Medicines are applied to the *conjunctiva*, under the name of *collyria*, to excite local effects only, though we might employ this part for other purposes, since remote effects may be obtained by it. Thus a

drop of hydrocyanic acid applied to the conjunctiva of a dog produces immediate death.

2. *Nasal* or *pituitary membrane.*—We seldom apply medicines to the *pituitary* membrane except in local diseases, or in affections of neighbouring organs. Sometimes they are applied to irritate this part, and excite a discharge: these are then called *errhines;* but when employed to excite sneezing, as when foreign bodies are in the nasal cavities, they are termed *sternutatories* or *ptarmics.*

3. *Bucco-guttural mucous membrane.*—Very rarely medicines are applied to the *mouth* and *throat*, except for local purposes. However, it has been proposed to excite salivation by rubbing calomel into the gums. Solids used in the mouth are termed *masticatories;* liquids are called *collutoria* or *gargarismata.*

4. *Eustachian membrane.*— Aurists now and then apply washes to the *Eustachian tubes* in local affections; but the occasions for this practice are rare, and the operation difficult, except in practised hands.

5. *Aërian* or *tracheo-bronchial membrane.*—Accidental observation, as well as experiments, have shown that medicines produce very powerful effects on the membrane lining the *trachea* and *bronchial tubes.* For the most part, applications here are made use of for local purposes, as in asthma, chronic bronchitis, phthisis, &c., though occasionally to affect the brain, the blood, the heart, &c. Dr. Myddleton has advocated the inhalation of substances (as cinchona, sulphate of iron, myrrh, &c.) reduced to an impalpable powder, in pulmonary diseases. The fumes (*suffitus*) of tar, balsam, resins, and other burning bodies, have also been employed in these cases. Sir Alexander Crichton has strongly recommended tar vapour; the method of using which is the following:—The tar employed should be that used in the cordage of ships; to every pound of which half an ounce of subcarbonate of potass must be added, in order to neutralize the pyroligneous acid generally found mixed with the tar, the presence of which will necessarily excite coughing. The tar thus prepared is to be placed in a suitable vessel over a lamp, and to be kept slowly boiling in the chamber during the night as well as the day. The vessel, however, ought to be cleansed and replenished every twenty-four hours, otherwise the residuum may be burned and decomposed,—a circumstance which will occasion increased cough and oppression on the chest.

The inhalation of aqueous vapour (*halitus*), either alone or with other substances, is oftentimes useful in various affections of the lungs and of the throat, &c. The apparatus for this purpose may be that proposed by Dr. Gairdner in the nineteenth volume of the Edinburgh Medical and Surgical Journal; or Dr. Mudge's inhaler; or in the absence of these, a teapot, or basin with an inverted funnel. In many asthmatic cases the difficulty of breathing is so great, that the patient cannot close the mouth around the tube, especially if the latter be small, without exciting a sense of impending suffocation. In such instances I have found the only easy and practicable method of enabling the patient to inhale aqueous vapour, is by holding the mouth over hot water contained in a basin or tea cup. Various narcotic and emollient herbs are sometimes added to the water, but I suspect without contributing in any way to its efficacy. The vapour of hot vinegar, of sulphuric æther, of iodine, of camphor, and of other volatile bodies, is occasionally employed in pulmonary diseases. The vapour of iodine may be conveniently inhaled by means of a double-necked glass bottle (fig. 21), into which we introduce about an inch of water, to which a few drops of the tincture of iodine have been added. Through one of the necks a straight glass tube passes, and dips under the surface of the water. The other neck has a short curved glass tube passing through it, by which the patient inhales. In the absence of a double-necked bottle we may use a common wide-mouthed bottle (fig. 22), the cork of which has two per-

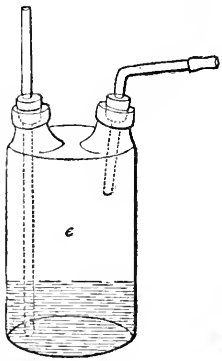

Fig. 21.

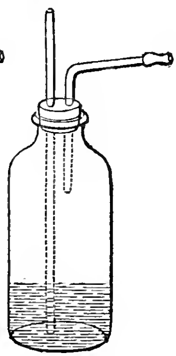

Fig. 22.

forations, through which pass the glass tubes. Chlorine gas may be inhaled in a similar manner, using a solution of the gas, or of chloride of lime, instead of the tincture of iodine. If oxygen, or nitrous oxide, be inhaled, the most easy and convenient mode of effecting it is from a bladder; but for other and more complete, though more costly methods, I must refer you to the works of the late Dr. Beddoes, and of the celebrated engineer, Mr. James Watt.

6. *Gastro-intestinal membrane.*—We em-

ploy both extremities of the *alimentary canal* for the exhibition of medicines; the upper, however, more frequently than the lower. This mode of employing medicines is called the *method by ingestion*. Of all parts of the body the gastro-intestinal surface is the most useful for the application of medicines. We presume that this arises from the great susceptibility, the active absorbing power, and the numerous relations, mechanical, functional, and sympathetic, which the stomach has with almost every part of the body. In many cases remote effects are more easily produced by this than by any other organ, as in the case of diffusible stimulants, and other agents which operate by sympathy. Medicines which act by absorption are more energetic when applied to some other parts, as the serous membranes, the bronchial membrane, the cellular tissue, &c. In some cases it is not only possible, but probable, that the stomach may digest, either partially or wholly, a medicine, and thus contribute to diminish the medicinal effect.

7. *Recto-colic membrane.* — Sometimes, though less frequently than the stomach, the *rectum* is employed for the application of medicines. It has been asserted that the general susceptibility of the rectum is only one-fifth of that of the stomach, and that medicines take five times as long to operate by the former as by the latter: hence it has been said that both the dose, and the interval between the doses, should be five times as great as when applied to the stomach. But this assertion is far from being correct universally, though it may be so occasionally. Orfila asserts that those agents operating by absorption, as opium and tobacco, are more active by the rectum than by the stomach; and he assigns as a reason the greater venous absorption of the rectum, and its less digestive power. But this statement is in direct opposition to the experience of almost every practitioner. Whenever I have had occasion to employ opium by way of enema, I always exhibit twice or three times the ordinary dose, without exciting any remarkable effects. Dr. Christison states that he has given two measured drachms of laudanum by injection, without producing more than usual somnolency, a quantity which, if Orfila's statement were correct, would probably prove fatal.

We apply medicines to the rectum sometimes with the view of alleviating disease of this or neighbouring organs (as of the uterus, bladder, prostate gland, &c.); at other times in order to irritate the rectum, and, on the principle of counter-irritation, to relieve distant parts (as the head); sometimes to produce alvine evacuations, or to dissolve hardened fæces; occasionally, also, when we are precluded from applying our remedies to the stomach, on account of their unpleasant taste and smell, the inability or indisposition of the patient to swallow, or the irritability of the stomach; and, lastly, in order to destroy the small thread-worm (*oxyuris vermicularis*).

When the substances applied to the rectum are solid, we name them *suppositories* (*suppositoria*, from *suppono*, to put under); but when they are of a fluid nature, we denominate them *clysters, lavements*, or *enemata*.

Formerly *suppositories* were usually either conical, or cylindrical like a candle, and of variable size,—sometimes one or two inches long. They are now usually made globular, and of small size. They are employed to evacuate the bowels; to irritate the rectum, and thereby to relieve affections of distant organs; but more commonly they are used as local agents in affections of the rectum, bladder, uterus, prostate gland, urethra, &c. I have frequently employed with great advantage a mixture of opium and soap, to prevent priapism during the night, in gonorrhœa.

Clysters or *lavements* require to be considered under several points of view: *first*, in reference to the material of which they are made, and which must vary with the object for which these remedies are employed; *secondly*, with respect to the quantity of liquid used, and which will depend on the age of the patient. The average quantity for an adult is about twelve or sixteen ounces; and I believe that it is rarely proper to use more than this. I am quite sure that the practice of introducing several pints of fluid into the large intestines, with the view of exciting alvine evacuations, is bad. In the first place it often provokes the contraction of the gut, by which the injection is immediately returned; and, secondly, repeated distention diminishes the susceptibility of the part, so that the ordinary accumulation of fæcal matter no longer acts as a sufficient stimulus. Mr. Salmon has related a case of this kind, where the patient had nearly lost all power of relieving the bowels, except by enemata or purgatives, and had produced dilatation of the rectum, in consequence of having been in the habit of introducing two quarts of gruel twice every day into the intestine. A newly-born infant requires about one fluid ounce; a child of one to five years, from three to four ounces; and a youth from ten to fifteen, from six to eight fluid ounces. *Thirdly*, the impulse with which the fluid is thrown up de-

serves attention. If too much force be used, the sudden dilatation of the gut may bring on spasmodic action of its lower part, by which the clyster will be returned. *Fourthly*, the instruments by which the injection is effected require notice. The common pipe and bladder are too well known to require description. I am inclined to think that the most convenient, safe, and useful apparatus, is the elastic bottle and tube. Any quantity of liquid, however small, may be thrown up with the greatest ease, and without any danger of the impulse being too great. Its application is exceedingly convenient; a lusty person, by placing one foot on a stool or chair, may easily apply it without assistance; and its price is very moderate. Another form of enema apparatus is a narrow water-proof tube, holding about a pint of liquid, about four feet long, narrower at one end, which is furnished with a common injecting pipe, and about two and a half inches in diameter at the other. The fluid being placed in the tube, the pipe is introduced into the rectum, and the apparatus held in a perpendicular direction, by which the fluid is propelled into the gut by its own gravity. This apparatus, although very simple, appears to me to be less convenient for common use than the elastic bottle, and not to be well adapted for the administration of small quantities of fluids. In the shops are sold syringes of various forms as enema apparatus, but they are more expensive than the common elastic bottle, without possessing any greater advantages or conveniences; indeed, they may become objectionable instruments, since their construction allows the liquid to be thrown up with great force.

Gaseous matters have been sometimes thrown into the rectum. Thus the injection of common air has been proposed in ileus; but I must refer you to the 16th volume of the Edinburgh Medical and Surgical Journal for further information on this point. Tobacco smoke has sometimes been employed in hernia: it is injected by a peculiarly constructed pair of bellows.

The *Urino-genital* mucous membrane, considered in reference to the application of medicines, includes the membrane lining the urethra and bladder, and that which lines the vagina and uterus.

8. *Urethro-vesical membrane.*—Applications to the *urethra* are made only for local purposes; either in a solid form, as caustic or medicated bougies, or in that of a liquid, as an injection: the latter is easily effected by a common syringe. Syringes of various kinds, for this purpose, are sold by Messrs. Maw, of Aldersgate-street.

Injections are sometimes thrown into the *bladder*, but always for local purposes. The operation is easily performed by attaching a catheter to an elastic bottle.

9. *Vagino-uterine membrane.* — Medicines are applied to the *vagina* and *uterus* to produce local effects only. Thus injections are thrown in, to relieve vaginal discharges, to excite the catamenia, &c. They are usually liquids, but the following case, told me by my friend Dr. Clutterbuck, proves that gases are sometimes employed. A lady, who had suffered a considerable time from some uterine affection, and had derived no relief from the treatment adopted, was advised to consult Dr. Rossi, an Italian physician. After he had examined the condition of the uterus, he assured her there was no organic disease, but merely a considerable degree of irritation; for which he proposed to apply carbonic acid, as a sedative agent. This was done by means of a pipe and tube, communicating with a gasometer situated in another room. The patient obtained immediate relief, and although she had been obliged to be carried to the Doctor's house on account of the pain experienced in walking, she left it in perfect ease. On her return to England she had a relapse of the complaint, and applied to Dr. Clutterbuck, to know whether she could have the same remedy applied in London, in order to save her the necessity of returning to Italy.

3dly. *Medicines applied to serous membranes.*—Irritating injections, such as wine and water, solutions of metallic salts, &c. are thrown into the cavity of the serous membrane of the testicle in hydrocele, in order to excite inflammation and the subsequent adhesion of the sides of the sac. Injections have also been made into the peritoneal sac in ascites, and in some cases with success. On this subject, however, I must refer you to the Philosophical Transactions for the year 1665.

4thly. *Medicines are applied to ulcers, wounds, and abscesses*, principally to excite local effects, and sometimes, though rarely, to produce a constitutional affection. Thus it has been proposed to apply corrosive sublimate to wounds, with the view of causing salivation.

5thly. *The injection of medicines into the veins* has been called *infusion of medicines.* The celebrated architect, Sir Christopher Wren, was the first person who undertook experimentally to determine the effects of medicines when thrown into the veins. His example was followed by Boyle, Clarke, Henshaw, Lower, and others. The partisans of this method of treatment asserted, that when medicines are administered by the stomach, their effects are much modified by the digestive process; and, therefore, by injecting our remedies at

once into the veins, we avoid this modification of their properties. But this statement is not accurate, since Drs. Christison and Coindet have shown that some substances are decomposed even in the blood, or at least they cannot be recognized in this fluid. Further, they have shown that the effects of medicines thus administered are of the same general nature as when their agents are applied to the skin or stomach; thus, tartar emetic vomits, senna purges, opium stupifies, and so on. There are, on the other hand, several objections to this practice; such as the danger of introducing air into the veins, or of throwing in too large a dose of the remedy (for a slight excess may prove fatal), or of the occurrence of phlebitis. These, then, are sufficient reasons for not resorting to this practice except on very urgent occasions; for example, to excite speedy vomiting when the patient is unable to swallow. Köhler preserved the life of a soldier, in whose throat a piece of beef tendon was sticking, by throwing a solution of six grains of tartar emetic into a vein of the arm: vomiting was induced, and the meat expelled. Knoph threw four grains of this substance, dissolved in an ounce and a half of warm water, into the veins of a man choked by a piece of beef: in one minute vomiting came on, and the beef was expelled. A similar case has been reported by Smucker.

In some obstinate and dangerous diseases this operation is sometimes admissible as a last resource; for example, in cases of poisoning, in hydrophobia, in malignant cholera, &c. As plethora appears to diminish absorption, it has been proposed to throw tepid water into the venous system in cases of narcotic poisoning, and thus to cause artificial plethora, in order to prevent the occurrence of the symptoms of poisoning by stopping absorption. Verniere found three grains of nux vomica produced no effect when applied to a wound in a dog into whose veins water had been thrown; and he asserts that by the early use of aqueous injections we may prevent the development of contagious diseases. Magendie has tried the effects of injecting tepid water into the veins in hydrophobia. The operation was first performed at the Hôtel Dieu, at Paris, in October 1823: the convulsions were stopped, but the patient died in a day or two afterwards. This operation has been several times repeated, and with the same results. In June 1832, I tried it on a patient (afflicted with this terrible disease) under the care of Mr. Bennett, of the Commercial Road. The patient was a boy, about nine years of age; he was nearly insensible at the time I performed the operation. I threw in about one quart of tepid water, without any obvious effect on the pulse: no convulsions were subsequently observed, but the patient died in a few hours. A solution of salt in water was injected into the veins in the malignant cholera, and often with apparent advantage. Purgatives, narcotics, &c. have been thrown into the veins by different physiologists, and in most cases the effects observed were of the same kind, though varying in degree, as when these substances were taken into the stomach. To this statement, however, the oils are an exception; for when injected into the veins they interrupt the circulation, and produce a kind of asphyxia.

Application of galvanism. — In the foregoing remarks on the different means of administering medicines, I have not noticed a recent proposal to introduce active medicinal agents (such as quinia and morphia) into the system by the aid of galvanism. *A priori* the idea seems feasible, and worthy of trial. We know that a variety of substances can be readily passed through animal membrane by means of the electrical agent; for example, if you place a solution of iodide of potassium in a glass tube (fig. 23), the bot-

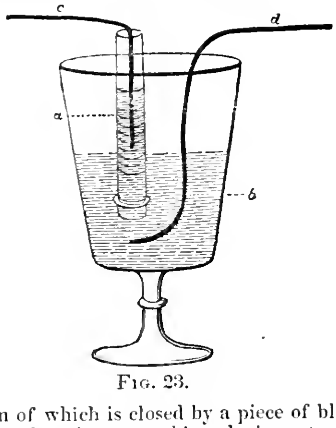

Fig. 23.

tom of which is closed by a piece of bladder; then immerse this tube in water (or rather a solution of common salt), containing some starch (letter *b*), and connect the solution of the iodide with the negative electrode, or pole (*c*), of a galvanic battery of fifty or one hundred pairs of plates, and the starch liquid with the positive electrode, or pole (*d*), you will observe in a few seconds that the starch is rendered blue by its combination with iodine, showing that this substance must have passed through the bladder to have come in contact with the starch. On examination not the least trace of perforation can be seen in this membrane. Now if we could on this principle introduce medicines into the system, or into tumors, it would be a con-

siderable practical improvement of our profession. In bronchocele we should have an easy method of conveying iodine into the swelling; in constipation a pleasant method of acting on the bowels. I throw out this hint for such of you as may feel disposed to follow up so interesting an inquiry.

ON THE

EFFICACY OF ICE IN DYSPEPTIC DISORDERS.

To the Editor of the Medical Gazette.

SIR,

I AM not conscious that any medical writer has noticed the use of ice and iced liquids in the treatment of stomach derangements. If not, you will perhaps give publicity to the following communication, the object of which is to propose another remedy for that distressing and widely-spread class of disorders, at once the offspring and the bane of highly-civilized and luxurious states of society. My attention, I confess, was first called to this subject by a lady, who, when in Italy, had derived great benefit from eating ice in a dyspeptic attack under which she then laboured. I had also very often remarked, as well as personally experienced, the refreshing influence of ice in languid states of the stomach, restoring the palled appetite, and re-invigorating the whole frame.

It occurred to me, besides, that I had not unfrequently seen persons of very delicate digestions, who durst not venture on a spoonful of cream at ordinary temperatures, eat of it largely in a frozen state, not only with impunity, but to the manifest advantage of their health. In regard to wine, also, it is notorious that the enfeebled stomach will endure much larger draughts of this intoxicating drink, without inconvenience, when it has previously undergone the process of icing.

Reflecting on these facts, it appeared to me highly probable that extreme cold, immediately applied to the secreting surface of the stomach, would be found a remedial agent of great value in the various affections of this sensitive and sympathizing organ. Without delay, therefore, I prescribed the ice freely in such gastric derangements as chanced to fall in my way, and quickly discovered that I had not formed an undue estimate of its powers. Relief almost immediate was the consequence in many cases of mere functional disturbance; and in those of a more fixed and structural character, it evinced a marked superiority over all other remedies in controlling the most distressing and refractory symptoms. To this practice, as opportunity offered, I have now adhered for years past; and so favourable has been the general result, that I feel more than ever anxious to recommend it to the consideration of my professional brethren.

I will not occupy your pages, sir, with a tedious recital of the numerous cases in which my confidence in the remedy here proposed is grounded, choosing rather, on the best authority, to illustrate my conclusion by an instance or two of general application*; and the first instance I shall adduce happened to a lady of delicate constitution, who had repeatedly suffered from functional derangements of stomach. On these occasions she experienced the usual symptoms of dyspepsia severely, attended sometimes by palpitations of the heart, and not without evidence of spinal irritation. Her recovery from such attacks was usually very slow under ordinary treatment. I therefore thought it advisable she should make trial of the (so to call it) "*refrigerant method.*" The ice was freely administered; the lady obtained almost immediate relief, and her recovery was rapid beyond all former example. Several times since she has resorted to the same plan with equal success; and now, by a timely application to it, she is enabled to ward off the severity of these attacks altogether.

The next and the only other instance to which I shall at present allude, occurred in a gentleman of the military profession, whose digestion had become impaired by long residence in hot and unhealthy climates, and which, continuing for some time after his return to England, at length terminated in a fixed

---

* "Unum adhuc restat de quo monendus est lector, mihi in animo non esse, sequentes paginas infinito particularium observationum numero distendere, quibus methodo ibidem traditæ fidem adstruam: frustrà enim, et cum tædio lectoris, repeterentur ista singulatim, quæ in summas contraxi. Satis autem habui, ad calcem observationis cujuslibet generalis, particularem hic illic adnectere, qua methodi præcedentis medulla contineretur."—*Vide Sydenham, Præfat. v. finem.*

structural affection of the stomach. Besides other formidable symptoms, there was settled pain in epigastrio, increased on pressure, and especially on taking food, which was commonly returned almost as soon as swallowed, and along with it large quantities of thick, heavy, mucus. Of these matters, however, the stomach was wont to dispossess itself, not by the usual mode of retching and vomiting, but by a process of eructation or rumination. Continuing in this state some time, the body became weak and emaciated, and my advice was requested. I had the good fortune to allay, in some measure, the pain and irritability of stomach by the free application of leeches and blisters, followed up by anodyne and effervescent medicines; but the advantage was only transient. In a few days these distressing symptoms returned with redoubled violence, insomuch that the stomach would now literally retain nothing, the mucous discharge being at the same time more troublesome and copious than ever, and occasionally a little tinged with blood. At this difficult juncture I could think of no alternative but the refrigerant plan, as I have already called it. I therefore ordered a plentiful supply of iced milk. The patient ate it with avidity. It sat comfortably on his stomach, abating the pain and suspending the mucous discharges almost wholly during the short remainder of my attendance. This case, I need scarcely add, in the end proved fatal; and my only object in citing it, is to shew the extraordinary control of intense cold over some of the most intractable symptoms of gastric disorder. In thus extolling its efficacy, however, I beg to disclaim all intention of pronouncing it infallible, being persuaded that nothing can so effectually overthrow the reputation of any novel and untried remedy as the proclaiming it a panacea. Some instances, I doubt not, there are (perhaps many), in which it will prove unavailing; and others, as gout, &c., in which it might justly be deemed inexpedient, and even dangerous. Nevertheless, I confidently look to the experience of others for the confirmation of what I have myself deduced from pretty extensive observation, viz. *that intense cold, as applied to the secreting surface of the stomach, will generally be found a remedy of great value and avail in the disorders of that all-important organ.*

Leaving it, however, to time to establish or refute this opinion, it shall be my object, in the meanwhile, to inquire how far it is sanctioned by an appeal to acknowledged truths and rational principles. And in order to this, I shall advert to the well-known operation of cold on the surface of the body,—how it causes it to wrinkle and contract, and its blood-vessels to vanish from the sight. Often, indeed, does this cutaneous constriction proceed to the length of occasioning dangerous terminations to internal organs. Witness that almost endless catalogue of fevers and inflammations, whose common origin is exposure to cold. Again, in head affections that proceed from inordinate afflux of blood to that part, of what powerful avail are intensely cold applications! Then, as to internal surfaces, every one knows how effectual they are in restraining hæmorrhages, and in checking and resolving congestion and inflammation in various portions of the mucous system. With such analogies before us, is it not highly probable that the stomach also would, if similarly affected, experience similar benefit? And that it is, in the generality of its disorders, similarly affected,—that is, more or less in an irritative, congestive, or inflammatory condition, I gather from the pain and uneasiness so commonly felt in epigastrio in such cases, as well as from the known efficacy of topical evacuants in the removal of these symptoms. Other evidences there are to the same purport: but for the sake of argument, we will assume the truth of this opinion. We will suppose that in gastric diseases generally there is more or less of engorgement of the innumerable capillaries distributed to the interior of the great digestive organ. Ought we not to expect, as the necessary consequence of such a state, a proportional degree of pain or uneasiness in the epigastric region? Might we not also reasonably look for such an increase of sensibility in the part as would render the accustomed stimulus of alimentary matter almost intolerable? And would not this congestion or inflamed condition of the secreting surface cause it, after the example of other mucous surfaces (as in catarrh, dysentery, and the like) to pour forth its peculiar product in greater abundance, and so vitiated in quality as to create disturbances in the very function which

nature has assigned for its performance? Collect, then, these consequences; and is there any thing wanting to make a good general definition of gastric disorders? Assume the symptoms, and the engorgement plainly follows; admit the engorgement, and the symptoms are fairly deducible. Thus do these opposite hypotheses mutually serve to confirm and verify each other; and thus does it plainly appear, from an appeal to reason as well as fact, that, in the general run of affections of the stomach, the capillaries of that organ are in a greater or less degree of plethora and over-distention. This, perhaps, is their principal feature; and it is, I presume, only to be explained on the supposition of diminished tone or resistance in their coats, by virtue of which, blood, urged on by the ordinary force of circulation, rushes into them in undue proportion *. And, to ascend another link in the chain of causes, we cannot doubt but that this and every other instance of relaxation in capillary blood-vessels, must be referred to some impression previously made on the nerves with which they are in connexion, and under whose control they are, by the hand of nature, placed. Mysterious, indeed, is the process by which this physical change is effected, and so, perhaps, it will ever remain. To speculate about it, therefore, in the present state of our knowledge, would be but idle and unprofitable †.

But the fact itself is of unquestionable importance; for if that be admitted, the operation and efficacy of cold, in gastric diseases, is most obvious; there being no known remedy of greater power in restoring relaxed and weakened vessels to their proper tone and resistance.

Whether, therefore, we resort to analogical or hypothetical argument, or trust to the more sure guidance of experience and observation, still we arrive at the same conclusion. By the concurrence of every kind of proof of which the nature of the subject will admit, are we warranted in repeating our conviction, that ice and iced liquids will be found among the most valuable remedies for stomach complaints in general, whether functional or general.

It only remains that I thank you, sir, for the insertion of this communication in your excellent periodical, whose merits, as a record of authentic facts and useful information, are too well known and appreciated to need the commendation of your obliged correspondent,

F. Bailey, M.D.

Reading, Oct. 1835.

REMARKS ON

ANIMAL HEAT AND THE NERVOUS INFLUENCE,

In reference to Dr. Wilson Philip's Letter.

To the Editor of the Medical Gazette.

Sir,

I should be sorry to have misrepresented the views of Dr. Wilson Philip, or to have expressed too strongly any dissent from the conclusions of one to whom the science of physiology is under great obligations.

The passage to which Dr. Philip re-

* On this point I beg to be a little more explicit. Some years ago I inserted a paper in the Medical Repository, in which I endeavoured to shew (on the authority of Parry's experiments) that there reside in blood-vessels generally two opposing powers—the one, *elastic*, tending to increase, and the other *tonic* or *vital*, tending to diminish their capacity; and that, by a certain adjustment of these forces, the natural calibre or dimensions of such vessels would be determined. Supposing, therefore, the elastic property to remain invariable (which may in the present instance be fairly done), it is obvious, that whatever change should happen to any vessel in respect of its diameter or magnitude, must be the result of its vital contractility, or, in the language of Parry, its tonicity. That being *diminished*, the elastic power of the vessel would preponderate, and conspire with the *vis-a-tergo* to give it an augmented volume; in other words, to determine blood more freely into it. If, on the contrary, the vital contractility were to *increase* above its natural standard, it would prevail over its antagonist elasticity, and thereby lessen the size of the vessel and the quantity of its contents. It is to the former of these states, however, to which we here principally refer; it being that condition which we conceive to be essential to the existence of a great majority of diseases, and whose removal constitutes the cure.

† It may not, however, be amiss to notice the instantaneous manner in which this effect is sometimes produced. At the bidding of a moral impression, the cheek instantaneously becomes suffused, and its innumerable capillaries relaxed and overgorged with blood. Something analogous to this happens, I presume, to the stomach, whenever food enters it; especially if excessive, stimulant, or indigestible. If, then, to the injuries which this important organ is continually liable from these causes, we superadd such other as are of a mental, moral, or physical nature, how can it but be that the minute vessels of its interior lining should in the end become weakened and overloaded, and thus prove the fertile source of dyspeptic disorders, at which we have already hinted?

fers was written in 1823 *, and the expressions "animal heat, a secretion, or *tertium quid*, &c." were quoted from the early edition of Dr. Philip's "Experimental Inquiry," &c. If in his later edition he speaks of animal heat as something to be classed with the secretions, he still leaves in doubt what relation animal heat bears to them; whether it is a separate but connate effect of a common cause, or a secondary result, immediately caused by the chemical changes comprised in the formation of the secretions. In the recent additions to my paper, I have endeavoured to shew that the former of these alternatives (that animal heat is a *tertium quid* resulting from the action of the galvanic fluid on the blood), is unsupported by what we know of the properties of electricity as it can exist in the animal frame; and by pointing out the general law according to which heat must be chemically produced by the formation of the principles of the secretions, I venture to hope that I have rendered this latter alternative an explanation of the production of animal heat.

I admit that in my original paper the power of the spinal marrow to produce heat was too summarily denied; but I still think that its share in this process is only hypothetical. It is certain, that after the removal of the brain, some purely chemical changes do take place (viz. the absorption of oxygen and the production of carbonic acid, which also occur with blood out of the body), which, according to known laws, must produce heat; but that the spinal marrow, or any remaining part of the nervous system, has a similar power of producing heat, is a matter of mere speculation.

It would be well for the science of physiology if the nervous agency could be universally identified with electricity, and if its relations to secretions and muscular action, whether as a cause or only as an influencing agent, were fully understood. At present, although the researches of Dr. W. Philip and others, (especially the recent ones of M. Donné,) have proved the existence of electric currents in the body, yet this knowledge assists us little in the mysteries of vitality. As Dr. Alison has well remarked, electricity (as far as we at present know it) will afford no explanation of the diversity and peculiarity of the several secretions, or of a variety of the causes of muscular action; and whilst we admit the possibility of electricity having properties yet unknown, which may hereafter explain the various processes of organic life, we must for the present content ourselves with referring them to a cause of which we confess our ignorance, by calling it vitality.

I am, sir,
Your obedient servant,
CHAS. J. B. WILLIAMS.

Halfmoon-Street, Oct. 22, 1835.

* This passage was contained in the abstract published in the Transactions of the Medico-Chirurgical Society of Edinburgh, vol. ii.

A REMARKABLE CASE
OF
GALL-STONES CONNECTED WITH DELIRIUM TREMENS.

To the Editor of the Medical Gazette.

SIR,

IF you consider the following case worthy of notice, perhaps you will give it a place in your valuable journal.

I am, sir,
Your obedient servant,
H. S. CALDWELL, M.D.

Camberwell, Oct. 23, 1835.

Mr. B., who is about fifty years of age, was formerly an officer in the navy, and for some years past has been living upon a comfortable independency. His habits were generally considered sober, although not unfrequently he had recourse to spirits to aid digestion.

About the beginning of May last I was called up in the night to visit Mr. B. His countenance was then pallid, although agitated; tongue white, clammy, and tremulous; hands very unsteady; pulse and skin quite natural; the whole system free from pain. But what had produced the present alarm was a distressing delusion under which he had been labouring for several days, that his wife was endeavouring to wean from him the affections of his son and daughter by a former marriage. The absurdity of this was evident, and reasoning had a momentary effect of quieting his fears on the subject. But after a day or two he became so ungovernable that it was requisite to place him under restraint. For about two months he derived much benefit, under

the judicious care of Dr. Uwins, at Peckham Asylum; and his mind having become more composed, he was allowed to return home. After Mr. B. left the Asylum, I occasionally attended him; and his general health, which was greatly debilitated, seemed to improve, but there were at times symptoms about him which threatened a relapse.

On Sunday, August 30th, Mr. B. was seized, while at church, with severe pain in the epigastric region, which was relieved after taking some ol. ricini. On the following evening the pain returned. I then saw him rolling upon a sofa, in great agony. The pulse and skin were natural; the pain *not* increased by pressure. Anodynes and antispasmodics were administered, but produced no relief. In a short time the urine became exceedingly high-coloured and muddy; while the fæces, on the contrary, were remarkably pale. As some obstruction appeared to exist in the biliary ducts, Mr. B. was treated accordingly. Previous to the 6th September there was no fever. The pulse then rose to above a hundred, and an acute pain was now felt under the edges of the ribs in both sides, as also under the scapulæ. After the application of leeches the pain subsided, and the pulse fell to eighty. After this, the white of the eyes became yellow, and gradually, in succession, the whole surface of the body. The tongue, as usual, was clammy and tremulous; but except in the commencement of the attack, there was neither nausea nor sickness; and during the intervals of pain the patient relished his food as usual.

On the 8th, while under the influence of medicine, something was heard to rattle in the night-pan, which proved to be *nine* gall-stones, the colour of verdigris. Next day he passed *five* more, and on the following day *one*.

A favourable change now took place in Mr. B.'s appearance and feelings, which was very evident to all who knew him. An aperient mixture, containing hydriodas potassæ, as previously prescribed, was taken daily, and all went on well until the 29th, when the pain again returned, and continued violently for six hours without intermission. Next day he passed *ten* more gall-stones; on the following day, October 1st, *three;* and on the 2d, *two:* in all, twenty-nine calculi, which are at present in my possession. Ten of them are as large as a middle-sized hazelnut; the others somewhat smaller, and nearly of a triangular form; the whole weighing 163 grains.

After passing these calculi, the excretions gradually became natural, and a very remarkable improvement has since taken place in Mr. B.'s health, both in body and mind. His complexion is now clearer than it has been for years past; and his temper, instead of being irritable and captious, has, to the great comfort of his excellent wife, become mild and agreeable.

P.S. This case is also well known to —— Phillips, Esq., Surgeon, Albion-Street, Hyde-Park Terrace.

M. BAUDELOCQUE'S

IMPROVEMENTS IN PRACTICAL MIDWIFERY.

To the Editor of the Medical Gazette.

SIR

As you did me the favour of inserting my former communication on the instrument invented by M. Baudelocque, I have been induced to send you the following account of his other suggestions and improvements in obstetrical practice, hoping that you will deem it of sufficient importance to be laid before your readers

I may here mention that the lateral curvature perceptible in the engraving given in the No. of your journal for Oct. 3, does not exist in the instrument itself, it being occasioned by the paper slipping whilst under the pantograph.

I am, sir,
Your obedient servant,
JOHN CHAS. COOKE,
Member of the Royal College of Surgeons, Edinburgh, and Licentiate of the Society of Apothecaries, London.

Coventry, Oct. 21, 1835.

In those rare cases in which, after the head has been crushed by the cephalotribe, the shoulders form the obstacle to delivery, M. Baudelocque has recourse to another instrument, which he terms a "double crochet mousse à lame cachée." I regret much that I have not an engraving of this instrument, as I fear it will be very difficult to convey a clear or distinct idea of it by verbal description alone.

It consists of a blunt hook, grooved on

its internal or concave surface, and of a steel rod inclosed in a canula, which is made to fit the groove: to the end of the rod a knife is attached, resembling very much in form that used by cheesemongers; it is made cutting on its convex edge and angles. The mode of using the instrument is as follows: the hook is first introduced in the usual manner, and the parts to be divided securely embraced by it. The operator then slides the canula, containing the steel rod furnished with the knife, along the groove, until he feels the edge of the knife in contact with the child's body. He now makes the canula firm in the groove, by means of a screw, and then, by turning another screw, he causes the blade to perform the section of the parts comprised between its edge and the groove in the concavity of the hook; the hook being kept steady by an assistant.

I confess that this instrument does not appear to me to possess the security from danger which the cephalotribe does; as, although the blade cannot slip out of the groove, and consequently can do no mischief with its convex edge, yet it is quite possible, that before it is wholly included in the curvature of the hook, the angle of the blade which is not in contact with the groove may wound the sides of the uterus or vagina. M. Baudelocque, however, confidently asserts that this will never be found to be the case.

He also recommends this instrument to be used in those cases of arm-presentation in which the child cannot be turned, and is indisputably dead.

A description of this instrument will be found in a thesis sustained at the School of Medicine in Paris by M. Boytier, entitled "De la section du tronc du fœtus mort." In this thesis there is also an engraving of the instrument. I do not know whether M. Baudelocque has ever found it necessary to have recourse to it in any of the cases in which he considers it to be applicable. I have, however, frequently been present when he has shewn that it is capable of cutting a child's body in pieces, out of the pelvis.

Another of M. Baudelocque's improvements in obstetrics is the compression of the abdominal aorta, in order instantaneously to arrest hæmorrhage occurring in the lower extremities or pelvis, whatever may be the cause. He first applied it exclusively to uterine hæmorrhage, but now considers it applicable to bleeding dependent upon wounds of the femoral artery, or its branches. It is done with the greatest facility when the abdominal parietes are lax and flaccid, as is the case immediately after delivery. Its advantages over the ordinary methods of restraining uterine hæmorrhage are, its facility of application, and the absolute command it gives us over the supply of blood to the abdomen and inferior extremities. M. Baudelocque has long been in the habit of instructing his pupils in the mode of compressing this vessel: the directions he usually gives are, to bring all the fingers of the right hand to a level with each other by placing the points of them on a board, or other flat surface, so as to ensure an equal degree of pressure being maintained on all parts of the calibre of the artery. The fingers being reduced to a level, they are to be applied about an inch above the umbilicus, and gradually, but firmly, pressed down until the artery is felt under them. If the fingers of the left hand be now applied to the femoral vessels, their pulsation will be no longer perceptible. Any one desirous of testing the value of this mode of compression may satisfy themselves by trying it on muscular individuals: they will meet with but little difficulty, even in them, and none at all in those reduced by disease, or exhausted by hæmorrhage. I believe M. Velpeau has published a case which peculiarly shews the value of this mode of compression:—A butcher's boy in Paris divided the femoral artery, immediately after it emerges from under Poupart's ligament. A pupil of M. Baudelocque, who was present at the time of the accident, had presence of mind enough to compress the aorta until M. Velpeau arrived, and to maintain it until the latter had secured the external iliac: the hæmorrhage was arrested immediately the compressfon was applied, and the boy recovered.

If the case be one of uterine hæmorrhage, M. Baudelocque also stimulates the uterus to contract by small doses of ergot of rye, repeated at short intervals: he has also invented a spring bandage, by which the compression may be maintained for any length of time which may be required.

The last of M. Baudelocque's sug-

gestions which I shall notice, is that of passing a hollow tube into the mouth of children, when the head cannot be instantly extracted, and pulsation can no longer be felt in the funis. I have not seen any case in which this has been necessary, but in the No. of the Medical Gazette for Oct. 10, 1835, I find two cases recorded in which M. Baudelocque has succeeded in preserving the life of the child under these circumstances.

I have occupied a much larger space than I could have wished, but I feel convinced that these inventions and suggestions of Baudelocque deserve to be better known in this country than I have reason to believe is the case.

REPORT OF FRACTURES

TREATED IN THE LONDON HOSPITAL DURING SEPTEMBER.

To the Editor of the Medical Gazette.

SIR,

THE following is the statistical account of the fractures admitted at the London Hospital during the month of September. I have endeavoured more accurately to ascertain the side of the body on which the fractures of particular bones more frequently occur, in order that we may not too hastily draw our conclusions: I have therefore been more careful in my arrangement. The fractures amount to fifty in number, and bear the following proportions:—

		Right.	Left.	Unknown.	
Cranium	1	..	..	..	
Cervical vertebræ	1	..	..	..	
Pelvis	1	..	..	..	
Scapula (acromion)....	1	..	1	..	
Clavicle	7	2	4	1	
Ribs	7	1	6	..	
Humerus	3	1	2	..	
Forearm (both bones) ..	1	..	1	..	
Ulna	4	1	3	..	
Radius	4	1	3	..	
Metacarpus	2	1	1	..	
Finger	1	1	..	..	
Femur	6	2	4	..	2 of the cervix.
Leg (both bones)	5	2	2	1	
Tibia	1	..	..	1	
Fibula	3	..	3	..	
Metatarsus	1	1	..	..	
Toe	1	..	..	1	
	50	13	30		

I shall take the liberty of detailing the case of fractured pelvis, as it presents points of considerable interest.

September 19th.—A boy, 15 years of age, was brought in, having been knocked down and run over. The wheel of a cart had passed up between his legs, and had traversed the right side of the pelvis obliquely upwards. A wound was produced under the scrotum of about an inch in extent, through which a quantity of apparently venous blood passed. The right lower extremity seemed to the eye shorter than the left, but on accurately measuring from the spine of the ilium to the patella no difference was observable; the shortening was therefore attributed to some displacement of the bones of the pelvis. A rupture of the urethra being suspected, an elastic catheter was passed down the urethra, but could not be directed into the bladder; the fore-finger introduced into the wound readily felt the extremity of the catheter. After some unsuccessful attempts to pass the instrument, I dilated the wound of the perineum, and, after considerable difficulty, observed the lower portion of the ruptured urethra surrounded by the corpus spongiosum; the end of the elastic catheter was now directed along the

urethra into the bladder, where it was retained in such a manner that the water might dribble through it. Although the pelvis on depressing the ilia alternately, possesses more mobility than natural, no crepitation could be perceived. The boy was sick, and complained of the sudden inflation of his abdomen, which was tender on pressure; the urine was bloody, and did not pass freely through the catheter. These signs distinctly indicated a rupture of the bladder. A large opiate by the mouth, and in the form of an enema, procured him some sleep, but he sank the next day.

Sectio Cadaveris. — The peritoneal covering of the intestines exhibited marks of inflammation. The fundus of the bladder was ruptured through the peritoneal covering, and the mucous membrane of this viscus slightly protruded through the edges of the wounded aperture. Slight ecchymosis of the coats of the bladder. The right pubis was fractured near the symphysis, and the fracture extended across the ala of the ilium of the same side, near the sacro-iliac symphysis. The cellular tissue of the pelvis was extensively ecchymosed.—I am, sir,

Your obedient servant,

JOHN ADAMS.

New Broad-Street, Oct. 1835.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Experiments and Observations on the Gastric Juice, and the Physiology of Digestion. By WILLIAM BEAUMONT, Surgeon in the U. S. Army.

"I MAKE no claim to originality in my opinions, as it respects the existence and operation of the gastric juice. My experiments confirm the doctrines (with some modifications) taught by Spallanzani, and many of the most enlightened physiological writers. They are experiments made in the true spirit of inquiry, suggested by the very extraordinary case which gave me an opportunity of making them. I had no particular hypothesis to support; and I have therefore honestly recorded the result of each experiment exactly as it occurred.

"The reader will perceive some slight seeming discrepancies, which he may find it difficult to reconcile; but he will recollect that the human machine is endowed with a vitality which modifies its movements in different states of the system, and probably produces some diversity of effects from the same causes.

"I had opportunities for the examination of the interior of the stomach, and its secretions, which has never before been so fully offered to any one. This most important organ, its secretions and its operations, have been submitted to my observation in a very extraordinary manner, in a state of perfect health, and for years in succession. I have availed myself of the opportunity afforded by a concurrence of circumstances which probably can never again occur, with a zeal and perseverance proceeding from motives which my conscience approves."

Nothing can be more modest and single-minded than this: it is conceived and expressed in the spirit of philosophy and truth; and for ourselves we yield a ready credence to all the statements and most of the deductions. Sure are we that the first are sincere, and the second, if not demonstrable, are certainly not yet disproved. The subject of the observations and experiments, ALEXIS ST. MARTIN, a Canadian, 18 years of age, robust and healthy, was, on the 6th of June, 1822, accidentally wounded by the discharge of a musket. The following is the description, when Dr. Beaumont first saw him:—

"The charge, consisting of powder and duck shot, was received in the left side of the youth, he being at a distance of not more than one yard from the muzzle of the gun. The contents entered posteriorly, and in an oblique direction, forward and inward, literally blowing off integuments and muscles of the size of a man's hand, fracturing and carrying away the anterior half of the sixth rib, fracturing the fifth, lacerating the lower portion of the left lobe of the lungs, the diaphragm, and perforating the stomach.

"The whole mass of materials forced from the musket, together with fragments of clothing and pieces of frac-

tured ribs, were driven into the muscles and cavity of the chest."

This remarkable patient went through some of the severest vicissitudes incident to accidental disease. In June, 1823, twelve months from the date of the accident, he was recovered sufficiently to perform light work; the injured parts were all cicatrized except the aperture of the stomach; thus described:—

"At the point where the lacerated edges of the muscular coat of the stomach and intercostal muscles met and united with the cutis vera, the cuticle of the external surface and the mucous membrane of the stomach approached each other very nearly. They did not unite, like those of the lips, nose, &c., but left an intermediate marginal space, of appreciable breadth, completely surrounding the aperture. This space is about a line wide; and the cutis and nervous papillæ are unprotected, as sensible and irritable as a blistered surface abraded of the cuticle. This condition of the aperture still continues, and constitutes the principal and almost only cause of pain or distress experienced from the continuance of the aperture, the introduction of instruments, &c. in the experiments, or the exudation of fluids from the gastric cavity."

In May, 1825, the experiments related in this work were commenced at Fort Mackinac, Michigan Territory. Part of these experiments were published in 1826, in the 29th number of the Philadelphia Medical Recorder. The patient remained in Canada four years, married, and begat two children, which he worked hard to maintain until 1829, when the wound was in the same condition as in 1825. In the service of Dr. Beaumont he laboured constantly, procreated "more children, and enjoyed as good health and bodily vigour as men in general." In 1831 he left the Doctor's service, went to, and remained in, Canada during the devastations of the cholera, himself going unscathed. In November, 1832, he re-engaged himself to his kind and philosophical master, for the express purpose of submitting to another series of experiments. During the whole of this term, from 1824, he has enjoyed general good health; "and he *now* enjoys the most perfect health and constitutional soundness, with every function of the system in full force and vigour." It is not necessary to detail the mode of obtaining the gastric juice, but it may be mentioned that "*bright yellow bile sometimes flows through the tube introduced into the stomach.*"

"The chymous fluids are easily taken out by depressing the valve within the aperture, laying the hand over the lower part of the stomach, shaking a little, and pressing upwards. In this manner any quantity necessary for examination and experiment can be obtained.

"*Valve.*—The valve mentioned above is formed by a slightly inverted portion of the inner coats of the stomach, fitted exactly to fill the aperture. Its principal and most external attachment is at the upper and posterior edge of the opening. Its free portion hangs pendulous, and fills the aperture when the stomach is full, and plays up and down, simultaneously with the respiratory muscles, when empty.

"On pressing down the valve when the stomach is full, the contents flow out copiously. When the stomach is nearly empty, and quiescent, the interior of the cavity may be examined to the depth of five or six inches, if kept distended by artificial means; and the food and drinks may be seen entering it, if swallowed at this time, through the ring of the œsophagus. The perforation through the walls of the stomach is about three inches to the left of the cardia, near the left superior termination of the great curvature. When entirely empty the stomach contracts upon itself, and sometimes forces the valve through the orifice, together with an additional portion of the mucous membrane, which becomes completely inverted, and forms a tumor as large as a hen's egg. After lying on the left side and sleeping a few hours, a still larger portion protrudes, and spreads out over the external integuments, five or six inches in circumference, fairly exhibiting the natural rugæ, villous membrane, and mucous coat, lining the gastric cavity. This appearance is almost invariably exhibited in the morning, before rising from his bed."

The remainder of the volume relates *every variety* of experiment practicable, and which could suggest itself to an ingenious and zealous seeker after truth. A selection of the experiments were in-

vidious, and certainly uninstructive if partially related; therefore as our limits exclude the whole, we must content ourselves and our readers by presenting merely the corollaries; they will furnish interest to all, and excite some to the prosecution of the subject, without, however, the same advantages as were furnished to Dr. Beaumont by the misfortunes of Alexis St. Martin.

"*Inferences from the foregoing Experiments and Observations.*

"1. That animal and farinaceous aliments are more easy of digestion than vegetable.

"2. That the susceptibility of digestion does not, however, depend altogether upon natural or chemical distinctions.

"3. That digestion is facilitated by minuteness of division and tenderness of fibre, and retarded by opposite qualities.

"4. That the ultimate principles of aliment are always the same, from whatever food they may be obtained.

"5. That the action of the stomach and its fluids are the same on all kinds of diet.

"6. That the digestibility of aliment does not depend upon the quantity of nutrient principles that it contains.

"7. That the quantity of food generally taken is more than the wants of the system require; and that such excess, if persevered in, generally produces, not only functional aberration, but disease of the coats of the stomach.

"8. That bulk, as well as nutriment, is necessary to the articles of diet.

"9. That oily food is difficult of digestion, though it contains a large proportion of the nutrient principles.

"10. That the time required for the digestion of food is various, depending upon the quantity and quality of the food, state of the stomach, &c.; but that the time ordinarily required for the disposal of a moderate meal of the fibrous parts of meat, with bread, &c. is from three to three and a half hours.

"11. That solid food of a certain texture is easier of digestion than fluid.

"12. That stimulating condiments are injurious to the healthy stomach.

"13. That the use of ardent spirits always produces disease of the stomach, if persevered in.

"14. That hunger is the effect of distention of the vessels that secrete the gastric juice.

"15. That the processes of mastication, insalivation, and deglutition, in an abstract point of view, do not, in any way, affect the digestion of food; or, in other words, when food is introduced directly into the stomach, in a finely divided state, without these previous steps, it is as readily and as perfectly digested as when they have been taken.

"16. That saliva does not possess the properties of an alimentary solvent.

"17. That the first stage of digestion is effected in the stomach.

"18. That the natural temperature of the stomach is 100° Fahrenheit.

"19. That the temperature is not elevated by the ingestion of food.

"20. That exercise elevates the temperature; and that sleep or rest, in a recumbent position, depresses it.

"21. That the agent of chymification is the gastric juice.

"22. That it acts as a solvent of food, and alters its properties.

"23. That its action is facilitated by the warmth and motions of the stomach.

"24. That it contains free muriatic acid, and some other active chemical principles.

"25. That it is never found free in the gastric cavity; but is always excited to discharge itself by the introduction of food, or other irritants.

"26. That it is secreted from vessels distinct from the mucous follicles.

"27. That it is seldom obtained pure, but is generally mixed with mucus, and sometimes with saliva: when pure it is capable of being kept for months, and perhaps for years*.

"28. That it coagulates albumen, and afterwards dissolves the coagulæ.

"29. That it checks the progress of putrefaction.

"30. That the pure gastric juice is fluid, clear, and transparent; without odour; a little salt, and perceptibly acid.

"31. That like other chemical agents, it commences its action on food, as soon as it comes in contact with it.

"32. That it is capable of combining with a certain and fixed quantity of

* I have now (Nov. 1, 1833, in my possession some clear gastric juice, possessing all its original properties, unchanged and undiminished, which was taken from the stomach in December 1832, about eleven months ago, and has been kept tightly corked in phials.

food, and when more aliment is presented for its action than it will dissolve, disturbance of the stomach, or 'indigestion,' will ensue.

"33. That it becomes intimately mixed and blended with the ingestæ in the stomach, by the motions of that organ.

"34. That it is invariably the same substance, modified only by admixture with other fluids.

"35. That gentle exercise facilitates the digestion of food.

"36. That bile is not ordinarily found in the stomach, and is not commonly necessary for the digestion of food; but

"37. That, when oily food has been used, it assists its digestion.

"38. That chyme is homogeneous, but variable in its colour and consistence.

"39. That towards the latter stages of chymification, it becomes more acid and stimulating, and passes more rapidly from the stomach.

"40. That water, ardent spirits, and most other fluids, are not affected by the gastric juice, but pass from the stomach soon after they have been received.

"41. That the inner coat of the stomach is of a pale pink colour, varying in its hues, according to its full or empty state.

"42. That, in health, it is constantly sheathed with a mucous coat.

"43. That the gastric juice and mucus are dissimilar in their physical and chemical properties.

"44. That the appearance of the interior of the stomach in disease, is essentially different from that of its healthy state.

"45. That the motions of the stomach produce a constant churning of its contents, and admixture of food and gastric juice.

"46. That these motions are in two directions; transversely and longitudinally.

"47. That the expulsion of the chyme is assisted by a transverse band, &c.

"48. That chyle is formed in the duodenum and small intestines, by the action of bile and pancreatic juice on the chyme.

"49. That crude chyle is a semi-transparent whey-coloured fluid.

"50. That it is further changed by the action of the lacteals and mesenteric glands. This is only an inference from the other facts. It has not been the subject of experiment.

"51. That no other fluid produces the same effect on food that gastric juice does; and that it is the only solvent of aliment."

MEDICAL GAZETTE:

Saturday, October 31, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo venlendi in publicum sit, dicendi periculum non recuso."

CICERO.

ACCIDENTS IN MINES.

DR. FIFE, of Newcastle, has published a pamphlet * which we are sure will interest many readers, and, we doubt not, far more than interest, if it do not alarm, others who hear — not without a shudder — the lamentable accidents which happen, from time to time, in our mining districts. The object of Dr. Fife is praiseworthy: he wishes to awaken the public attention to the deplorable sacrifice and loss of life which takes place so frequently in the coal mines, and to excite, if possible, the energies of those who have the power, as it is to be hoped they have the will, to remedy so shocking an evil.

Few things are more wretchedly mismanaged by our government than those which belong to a sound medical police. It is true that in a few instances we have indications that such objects as those to which we allude are not overlooked: we have our medical inspectors of prisons, of lunatic asylums, and professional commissioners to take cognizance of the due apportioning of labour in the factories. But there are numerous other respects in which an attention to the public safety is not sufficiently, if at all,

* A Critical Analysis of the Evidence adduced at the Inquest occasioned by the late Explosion at Wallsend Colliery, &c. &c. By George Fife, M.D., &c. &c.

given: the State seems to take no account of the loss of its subjects, or of the dreadful mode in which their lives are squandered. There are no medical commissioners whose duty it is to inspect the condition of the coal mines. Is this right—is it expedient—where the consequences are attended with such awful calamities?

Our readers must have learned from the newspapers the particulars of the catastrophe which occurred at Wallsend colliery in June last. An inquest was held on the bodies of the sufferers, and several startling facts were elicited in evidence. To Dr. Fife we are indebted for preserving the minutes of some of the most important circumstances disclosed, as well as for some valuable remarks which he has appended,—coming from him with peculiar propriety, as he has himself served the office of Coroner, and is at present a lecturer on Forensic Medicine at the Newcastle Medical School.

The Bensham seam, in which the explosion took place, is admitted on all hands to have always been a most dangerous locality; and Mr. Buddle, the eminent mining engineer who was examined at the inquest, says it required the utmost care to keep it in a workable state: this was chiefly managed by adopting what was supposed to be the most efficient system of ventilation.

But it is quite clear from the evidence, as well as from the principles laid down by Mr. Buddle himself, in his account of the explosion which took place at the Jarrow colliery, that sufficient care was not observed in ventilating the Bensham seam. To a question proposed by the Coroner, as to whether the latter pit did not give out a greater quantity of inflammable air than any other, Mr. Buddle replied, "It is a difficult question to answer; I must confess I have not seen any pit where extreme precaution was more necessary." From a further examination of the same gentleman, it appears that "the Bensham seam *abounds* in inflammable air. I shall take," continued Mr. Buddle, "for example, the quantity which is now in a state of combustion night and day at the top of the gas-pipe, at the coal-pit. This stream of gas issues from a detached portion of the workings, about five acres in area. The quantity, as gauged, issuing from that pipe is *eleven hogsheads per minute;* and supposing this volume of gas was suffered to pass through the workings, instead of being discharged at the pipe, *it would require from* 150 *to* 160 *hogsheads per minute of atmospheric air to dilute it below the firing point*, so as to admit of its being safely carried through the fire of the furnace."

Of the nicety with which the proper supply of atmospheric air requires to be adjusted for the purposes of safety, we may have some idea from the following extract, taken from Dr. Fife's pamphlet. Let it be kept in mind, that various quantities of inflammable air are evolved in mines at different times, and that there is often no possibility of predicting the moment when an enormous quantity may issue forth to the destruction of human life:—

"In Mr. Buddle's account of the explosion which took place at Jarrow colliery, there are some excellent remarks on the effect exerted by the atmosphere over the discharge of the inflammable air in coal mines. He observes, 'If the ordinary ventilation of a pit's workings should only be just adequate to the dilution of the quantity of inflammable air evolved, below the firing point, when the barometer stands at 30 inches, it would become quite inadequate whenever the barometer falls;'—'and, on the contrary, if the barometer should rise, the evolvement of inflammable air would be diminished.' It will be seen that this accords with a remark made by me in a former part of this pamphlet, in reference to the adequacy of the means for ventilating

'Wallsend colliery.' Mr. Buddle then says, 'Hence it is that we frequently find some of our coal mines in an explosive state when the barometer is low, while the presence of inflammable air is scarcely perceptible when the atmosphere is in a very dense state." Mr. Buddle then states that the *proximate* causes of explosions are three in number. 'First,—By a change in the density of the atmosphere, as indicated by the barometer.' Mr. B. states further, that he has known the 'whole circulating current of a pit's workings rendered explosive in the course of fifteen or twenty minutes.' This was the cause of the explosion at Wallsend in the year 1821, when *fifty-two lives* were lost. Mr. Buddle ascribes the accident to the '*too great* confidence of the overman in his own judgment, and that he had not given the usual alarm, 'Put out the lows!' in due time.' At the time of the accident the barometer stood at 28·8 inches. The second cause mentioned by Mr. Buddle is—'By the accumulation of the inflammable air in the 'threads' and fissures of the roof and pavement.' Mr. Buddle states that Backworth colliery was very subject to this cause of danger. Third—'By cavities, or large fissures, which do not seem to have any outlet.' 'This may be considered the most dangerous case, as it frequently happens that *a large quantity* of gas bursts out from those cavities, which occur in the roof and pavement as well as in the coal.' 'The great danger in this case arises from the *suddenness and great force* of the eruption, without giving sufficient warning for the escape of the colliers, or for allowing the persons in charge of them time to adopt the necessary measures of precaution.' This is what the miners call a 'bag of foulness.' This was the cause of the accident at Washington colliery in 1828. The explosion was occasioned by a 'bag of foulness' breaking down from the roof of the air course 'board,' behind the workmen, which at the same time, stopped the ventilation, so that a double cause operated in this instance to occasion the explosion: the 'stoppage of the ventilation, and an enormous discharge of inflammable air occurring at the same instant.' The accident at Jarrow was occasioned in a similar manner—viz. by the 'bursting out of a bag of foulness from a cavity in the coal.' Does any proof exist that the accident at Wallsend was not caused by a similar occurrence?"

This, however, constitutes by no means the whole of the risk incurred in the working of mines. We believe that the operations of nature owe a great proportion of their fatality to the unaccountable recklessness of the workmen and their overseers. The arrangements in this very Bensham seam must strike every one who inquires about them as being the most stupid and mischievously silly that can be conceived. In one part of the pit davies were used, and sometimes suffered to become red-hot before the alarm was taken; in another, not two hundred yards off, and with a free communication between the localities, *candles* were employed, and the beds of coal exploded by gunpowder. A naked oil-lamp, too, it appears, was suspended at no great distance from the dangerous part of the workings: and all this in the foolish trust that the actual ventilation would be sufficient to obviate all danger, and that the carburetted hydrogen *would not* drift to those situations where flame was nakedly exposed! Nay, this was not all; there were awful warnings for some time about the Bensham seam; and if its general character were not enough to inculcate caution, one should have thought that the occurrences of the 17th would have in some measure prepared any rational being for what so dreadfully took place on the 18th of June. But no; the hardihood of the miner seems to have no bounds. The operatives in our collieries are clearly persons not to be entrusted with the care of their own safety, and it is precisely for this reason that we think it the duty of the State to look to the matter.

We should lay some further extracts from the pamphlet before our readers, but that the evidence being of so complicated a nature makes it difficult to

select, without entailing the necessity of selecting other passages at the same time, which would go far towards neutralizing those first chosen. The truth is, that after all, the evidence adduced by the author of the pamphlet is vague, and in great measure inconclusive. After an attentive perusal, we confess ourselves at a loss to decide whether the calamity was owing simply to gross negligence, to accident, or to *design*. Our impression, however, is, that to the two former it must mainly be attributed. One thing ought not to be lost sight of in most cases of this kind—namely, that what would be the most valuable evidence is generally wanting: we mean that of the sufferers; but they rarely survive; in the present instance they all perished.

Dr. Fife, among the preventives which he suggests, lays great stress on the value of well-constructed Davy-lamps, properly furnished and attended to. He evidently thinks this of paramount importance, and challenges the statement of any well-authenticated case tending to invalidate his opinion. We believe him to be quite too sanguine on this point; for independently of the fact of its being now put beyond all doubt that the Davy-lamp is *not* secure,—that it explodes in currents of inflammable air—it has come to our knowledge that there have been cases where fire-damp in coal-pits has been exploded with terrible consequences by the lamp, and that —where no fault could fairly be imputed to those who had the adjusting of those supposed, but, as we think, too much trusted, guardians of safety.

SOCIETY OF APOTHECARIES—REGISTRATIONS.

THE number of pupils registered this season has been larger than ever before. *One thousand and fifty-five* entered their names at Apothecaries' Hall, up to the 21st instant.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

By Dr. Latham.

Medical investigation conversant exclusively with Matters of Fact—What Medical Facts are, and what they are not—The Observation and Collection of Facts—Their Arrangement, according to Analogy or Resemblance; according to the Relation of Cause and Effect—What is meant by the Relation of Cause and Effect between Medical Facts—Peculiar Difficulties in the way of ascertaining that Relation—The Task of ascertaining it necessary to our knowledge of the Sources of Disease; of the Influence of Remedies; and of the Connexion between the Disease and its Symptoms—The Sources of Disease, how easily and quickly ascertained in some instances; how tardily and difficultly in others—The Influence of Remedies, how liable to deception, from a vicious credulity on the one hand, and a vicious incredulity on the other—The Nature of General Principles in Medicine, and how they are reached.

CERTAIN observations which I formerly made * must be considered to comprise the *method* only in which the particulars of a case may be most conveniently surveyed: but more remains to be considered than the mere form of case-taking.

You may adopt this mode of case-taking, or any other which your own experience may make most convenient to you: but no method of recording the particular facts will be of any use to you, unless you have right notions concerning the *facts* themselves. The facts, in truth, *are* the case; and it is only for the sake of getting *sure* possession of them that we adopt any form of (what is technically called) case-taking.

Now the whole business of your lives will be the business of taking cases; not necessarily with pen, ink, and paper, or after any technical form. But still it will be the business of your lives really and essentially, and in the justest sense; for each case is made up of its own facts, and the facts alone must teach you the nature of the disease, and suggest the remedy in every patient you see. Therefore, as long as you live, you will be evermore conversant with facts, learning and collecting them, arranging and combining and separating them, tracing their relations, and through them arriving at general principles.

* Vide Med. Gazette, vol. xi. p. 193.

There are peculiar causes which will ever prevent medicine from arriving at the certainty of purely physical science. But in so far as it is *certain*; in so far as it has taken the form of a science at all; it is built upon the same foundation with all other sciences; namely, upon facts: and in so far as it is uncertain, beyond what, in its own nature, it ever need to have been; in so far as it has not deserved the name of a science; it is raised upon a foundation which never would have been deemed sufficient for any other department of human knowledge.

It is important, then, to the right judgment and the right treatment of every individual case that we see; it is important for the sake of preserving to medicine whatever claim it may have to the name of a science, and (I will add) for the sake of our own credit and satisfaction, that we should utterly reject all other foundation of professional knowledge except matters of fact.

I desire to convince you of this, by shewing you, first of all, what matters of fact in medicine really are, and what they are not.

Every man's notion concerning any department of knowledge is the popular notion, until it is rectified by further inquiry. The popular notion concerning medicine is, that diseases are separate essences, and that an idea can be formed of them apart from the living being in whom they occur; that a fever, or a pleurisy, would still be something real, although there were no living beings in whom they could manifest themselves.

But diseases are not abstractions: they are modes of acting different from the ordinary and healthy modes—modes of disorganizing, modes of suffering, and modes of dying: and there must be a living, moving, sentient body for all this.

Endeavour to understand this truth; and at the very entrance of your professional studies get rid of all abstractions, that you may never record them and use them (as they are and have been recorded and used) as matters of fact.

You may record that this man has a hot skin, a dry tongue, and a frequent pulse, and call his disease a fever; that this man has a pain in his side, difficult breathing, and a hard pulse, and call his disease a pleurisy; but beware of taking this fever or this pleurisy for more than they really are. The fever is nothing, and the pleurisy is nothing, but the complex of the several facts which you have recorded under the head of each: separate from them, they are mere names. The fever has no treatment, and the pleurisy has no treatment, but what is suggested by the facts included under each. You prescribe for the hot skin, the dry tongue, and the frequent pulse, and you bring back their condition to what is natural, and so cure the fever; and you prescribe for the pain in the side, the difficult breathing, and the hard pulse, and so cure the pleurisy. But if, without regard to the facts apparent in the individual patients, you pretend to address your remedies to the fever *itself*, or the pleurisy *itself*, you take aim at an absolute phantom.

Bear in mind, then, that abstractions are *not facts*; and next bear in mind that *opinions* are not facts. To record that a patient is *better* to day and *worse* to-morrow; that he is at one time doing *well* and at another doing *ill*; is to give a *summary opinion* upon the facts, not the *facts* themselves.

I do not mean to say that such summary opinions should not be formed, or that they should not be announced. We always *do* form them, and the patient, or the patient's friends, always require us to communicate them; and most justly. But to ourselves, and in communication with other medical men, either for the sake of marking the exact state of the disease or suggesting the remedy, they are utterly useless.

If, in going round the wards of the hospital, I had it punctually recorded that this, that, and the other patient, had a peritonitis, a nephritis, or a hepatitis; and that day after day, this, that, and the other patient were better, worse, or just the same; and if, day after day, I were to order bleeding, blistering, or purging, as the case might require, and thus you were to witness numerous instances of recovery; you would not reap the slightest benefit from me and my pretended instruction, although you went round with me for a twelvemonth. For this would be to keep industriously from your notice every thing in the shape of a *fact* by which you could estimate the nature and progress of the disease, or the operation and effect of the remedy.

In medical science, the only materials of our knowledge are those things which are referable to our sensations and perceptions: matters of fact. Such are the temperature of the skin; the number and qualities of the pulse; the quantity and qualities of secretion; functions and modes of action in the several parts and organs of the body; and all their cognizable deviations from what is natural: also pain; for although pain, as to its actual occurrence in a particular case, must be taken upon the testimony of the sufferer, each man's own experience must some time or other have convinced him that pain is a *fact*.

Such, too, are the conditions of parts discoverable after death; their increased or

diminished bulk; the changes of structure and injuries they have undergone, and the morbid products to which they have given origin. These are the sort of facts with which we have to do, if we would know diseases and how to treat them.

Such being the materials of our knowledge, it becomes important to consider how we can use them best and abuse them least; for the materials of our knowledge require to be hewn and squared, and fitted to their place, with much care, and skill, and diligence; otherwise, what might have been a seemly edifice, may chance to be no better than a heap of rubbish.

First, then, as to the *simple reception* of medical facts, there is a good deal to be learnt.

All facts are not of equal value: some are trivial and accidental, some important and essential to the subject. In your inquiries at the bed-side, you will have to select and to reject cautiously and discriminately. Patients themselves are apt to press upon their medical attendants symptoms (generally consisting of strange sensations) which are irrelevant to their present disease. Again: in your examinations by dissection, you will have to use much care, lest you should admit appearances as indicative of disease which are accidental, or may have arisen during the process of dissolution, or from the position of the body after death.

But in this sifting and separating of facts, be cautious of throwing away any thing that is really valuable. Beware of rejecting facts of which you do not, perhaps, comprehend the import, and because you do not comprehend it; but rather reject those which you *do* comprehend, and know them to be trivial. Be careful especially of not allowing their due weight to facts which appear contradictory to each other; rather examine them more scrupulously because they are so. For instance, a patient may have a severe pain in the side and a frightful dyspnœa, and the pain and the dyspnœa may have arisen suddenly. Such symptoms at once carry with them the suspicion of active inflammation, and our thoughts may immediately run upon copious bleeding. But the same patient may, in the meantime, have his skin cool, and his pulse soft and tranquil, and not more frequent than the pulse of health. Cases of this and of the like kind are not uncommon, in which symptoms of a contrary character neutralize the import of each other, disprove the suspected existence of a dangerous disease, and forbid the needless adoption of a severe remedy.

The more you exercise yourselves in the observation of medical facts, the more you will understand the sources of error to be avoided in the reception of them. Time and diligence, and constant intercourse with the sick, if you have but *an impartial and honest* mind, will enable you to lay up a large and useful store of genuine facts, and draw from it as the treasury of your future knowledge.

I say an *impartial* and an *honest* mind, because it is remarkable how apt some little favourite theory is to get early possession of the student's imagination, rendering him dishonest (perhaps unconsciously) in the simple reception of facts. It is like some little favourite sin in our moral nature, which taints the character of the whole man.

A premature desire to generalize, an eagerness to arrive at conclusions, and a readiness to rest in them, are very common infirmities, and they offer a very serious hindrance to the right acquisition of facts. For if the early habit of theorising does not often estrange the mind of the student from the wish to observe altogether, it may yet pervert the faculty itself in its very use and exercise; and then, be his wish what it may, he cannot observe honestly. He gives an undue weight to the facts which accord with his assumed principle, and no weight at all to those that conflict with it: habit forces him to do so, and he cannot help it.

A very good and wise man has explained this matter by an illustration, which is so beautiful and so true, that I must recite it to you:—"A watchmaker told me that a gentleman put an exquisite watch into his hands that went irregularly. It was as perfect a piece of work as was ever made. He took it to pieces and put it together again twenty times. No manner of defect was to be discovered, and yet the watch went intolerably. At last it struck him that the balance-wheel might have been near a magnet. On applying a needle to it, he found his suspicions true: here was all the mischief. The steel-work in the other parts of the watch had a perpetual influence on its motions; and the watch went as well as possible with a new wheel. If the soundest mind be *magnetized* by any predilection, it must act irregularly *."

In the reception of facts, then, it is essential, first, that they be fully ascertained—i. e. upon sufficient observation; 2dly, that they be fairly and honestly represented, without disguise, modification, or omission, to make them suit particular theories; 3dly, that they be important and essential to the subject—not trivial and merely incidental to it.

Next comes the arrangement of facts.

* Cecil's Remains—on judging justly.

Now, facts may be arranged according to certain characters of agreement observable between them. There is an agreement of analogy and an agreement of resemblance. *Analogy* is a loose sort of resemblance, in which points of agreement and points of difference are mixed up together. By separating twenty points in which they differ, and retaining the two or three in which they agree, multitudes of things may be brought into this loose kind of resemblance and classed together. Thus, *analogy* is enough to bring diseases together in the same nosological order, as Fevers. Then, again, by calculating what individuals of the general order have most points of agreement, and distinguishing them accordingly, we come to divide orders into genera; and by still further selecting the individuals of the genus which have most points of agreement, we find the species; and by dealing with the species in like manner, we may divide it again and again, until thus, from the relation of mere analogy, we reach that of a tolerably strict resemblance. This is the scheme upon which nosologies are constructed; and nosologies have their use, until we can arrive at something better. Better to arrange facts according to the relation of analogies and resemblances, than not at all.

But it is far better (if it were possible) to arrange them according to their natural sequences, i. e. according to the relation of cause and effect. Now, "our knowledge of cause and effect, in reference to any two particular events, is founded entirely upon the observation of a uniform sequence of the events; or of the one following the other in a uniform manner in a great number of instances. The greater the number of instances is in which the sequence has taken place, with the greater confidence do we expect it to take place again under similar circumstances; and every single instance in which it does not occur, weakens our confidence, unless we can discover some adequate cause by which the sequence was interrupted. The result of this confidence is, that when we observe the first of two such events, we expect the second to follow it; and that when we observe the second, we conclude the first has preceded it. The first we call cause, the second effect *."

The philosophical physician is evermore studying how, upon adequate grounds, he can assign to medical facts this relation. But he knows in how delicate and difficult a task he is engaged. He is obliged to wait upon experience, and to attend to phenomena as they happen to occur. He cannot bring them together at will, and vary and transpose them as he likes, so as to learn their connexion. He envies the ease with which the chemist can bring any substance within the sphere and influence of as many others as he pleases; and the accuracy with which he can then ascertain the degrees of affinity it bears severally to each,—an accuracy so precise, that he can express them by numbers.

Further: when the physician has ventured to draw such conclusions as his long observation seems to warrant, he cannot test their truth by any simple experiment. He has no litmus or turmeric paper to tell him whether the blood-vessels or the nerves are the prime agents in producing a certain form of fever; but what his long observation seems to have taught him, he must still wait for the same long observation to confirm or to confute.

Unfortunately for us, the nature of medical causation is such, that it takes as much time and trouble to rectify an error as to establish a truth. Thus it may require the experience of one man's life to arrive at some plausible theory, and the counter-experience of another man's life to shew that it is false.

The vast experience required to establish a uniform sequence of events, and the impossibility of applying any summary test to the truth of our conclusions, are difficulties inseparable from the nature of medical causation. They lie at the very root of the matter.

And beside these, there are others, from sources impossible to enumerate, which perpetually beset and waylay our path of inquiry, breaking in upon the uniform sequence of events, and disappointing the best conclusions of experience. Such are the influences of places, and seasons, and climates, and the wills, feelings, and propensities, and all that is understood by the constitution, corporeal and mental, of human beings.

But however hard the task may be, we must still try to know the true relation of the things which concern the ordinary practice of our profession: we *must* trace the influence of external agents as causes of disease; otherwise we can do nothing for its prevention. We *must* trace the influence of external agents as remedies; otherwise we can do nothing for its cure. We *must* trace, too, the connexion between certain symptoms and certain morbid processes going on within; otherwise we can adopt no rational treatment of individual cases.

Respecting the external causes of disease, you must make them your study as opportunities may present themselves to you. But there are some so important,

* Abercrombie; Intellectual Powers, 390.

that their investigation has become of itself a department of medical education;—I mean what is called "forensic medicine." And, indeed, I know no department of public teaching which, if it be entrusted to good hands, (and I am sure it is so in this hospital), promises more benefit to medical science and medical practice than this. It undertakes to illustrate the modes in which injury, disease, or death, arrive from those external agents or accidents that are most signally hurtful to animal life; from poisons of every kind; from lightning; from hanging and drowning; from corruption of the air; and from every method of simple violence. Thus forensic medicine is conversant with all the highest points of physiology and pathology; and its very purpose requires the greatest exactness in the nature and display of its proofs. It requires, in truth, that they should be so made out as to be obvious to such understandings as ordinary men are accustomed to bring with them into a jury-box.

Here, then, is provision made, within a large and interesting field, for demonstrating to you the effects of external agents as the causes of disease; and all *matters of fact*.

The display of the fatal effects resulting from the causes enumerated to several vital parts and organs, furnishes so many demonstrations of the possible ways in which the same parts and organs are capable of suffering from causes less hurtful. Not long ago, poisoning was an affair of the utmost darkness and mystery; but now the rationale of poisoning in its several kinds is so well made out, that I am able to refer to it for the best instances which pathology affords of cause and effect in the manifest influence of external agents and accidents for the production of disease.

Poisoning, and the severer injuries, are a sort of pathological experiments. They produce upon this or that organ all the phenomena which any conceivable disease can exhibit; and they produce them in the greatest simplicity, because the subject is often previously in a state of health. Thus it is that they furnish an admirable introduction to the study of (what is called) spontaneous disease in the same organs.

Very acute inflammations arising suddenly in a healthy body afford the *next best* instances of the effects of external agents as causes of disease. I am accustomed to regard them in the light of medical accidents: for although the inflammation come from no injury in the ordinary sense, yet it will generally be found to have followed the exposure of the body to influences which act with a kind of violence—such as sudden changes of temperature, or the use of meats and drinks which, from their preposterous kind or quality, have become in a manner poisonous. Thus, the external cause productive of inflammation, and the time of its application, are sometimes as accurately determined as a fall or a blow.

In proportion as diseases are more chronic, they are (upon the whole) less easily assigned to their external exciting causes. With respect to them, a longer experience and inquiry are needed to establish a uniform sequence of the events. If you are attentive observers in the wards of this hospital, it will require a brief period only to convince you that the sudden impression of cold is among the undoubted causes of acute inflammation in various vital organs. But you cannot know that the habitual indulgence in spirituous liquors is undoubtedly productive of congestion of the liver until after years of experience. For the present you must be content to take this fact upon trust from the testimony of others.

The questions of malaria, of contagion, and of animal poisons; the certainty of their influence as causes of disease; and the mode, the sphere, and condition of their operation, are all questions of the highest importance, and involving facts of great interest. But I would advise you not to meddle with these questions at present; for *at present* you can only do it *speculatively*: therefore it is better that you should wait until a sufficient number of facts have fallen under your notice, either to enable you to form some conclusions of your own upon these subjects, or to have a sound judgment of the conclusions which have been formed by others.

With respect to the influence of external agents as remedies, I would recommend you to be most jealously observant of every circumstance connected with the treatment of individual cases. A *mere sequence* of events is not a *necessary* sequence. The remedy may be administered, and the disease may cease; and yet the treatment and the cure may not be cause and effect.

The remedy may have been really *inert*; and the spontaneous powers of reparation in the constitution or in the part may have been enough to surmount the disease; or the remedy may have been *active* in the wrong direction, and the powers of reparation more than enough to surmount the disease,—enough both to surmount the disease and to render the remedy harmless.

Your only safeguard against such deception lies in the most jealous and scrupulous observation at the bed-side. Turn your attention first of all to well-marked

instances of disease which is acute and rapidly progressive, where the remedies must be of equal force with the disease, and must operate with equal rapidity, and from which, if a curative impression follows, it must be a *sensible* impression. Watch the treatment of inflammation in various vital organs by the different modes of bleeding, by calomel, by tartar emetic, by colchicum; and the treatment of certain convulsive and painful disorders, and certain forms of delirium, by opium.

Beware of mistaking the nature of the disease, and then believing that the remedy has cured what in fact never existed. I lately read a book in which a certain remedy was recommended as infallible for diseases by dozen: tic douloureux, ovarian dropsy, disorganization of the heart, paralysis, and I dont know what besides, were all cured by it. Of these diseases no description was given, but only the name; so that there was not the slightest evidence that any such diseases existed as those that were said to be cured.

In like manner there have been remedies for cancer, remedies for consumption, remedies for stone,—all owing their reputation to the nature of the disease being mistaken.

This is the field in which ignorance and imposture reap their golden harvests. Not that it is impossible for those of good intention and good information to mistake the character of a disease, and so ascribe an efficacy to a remedy which is not its own. But those have the best security against this error who have taken the most pains to acquire a habit of faithful and jealous observation.

But there is an opposite infirmity not uncommon among medical men, which is just as much to be deprecated as the easy credulity of which we have been speaking, a scepticism in regard to the influence of medicine—a stubborn reluctance to admit the relation of cause and effect between remedy and cure. Surely it is not at all less hurtful to take up a notion that a number of diseases, from their nature or seat, are beyond the reach of all remedies, than to believe that any or every disease that gets well after the use of any remedy is necessarily cured by it. In the one case things are linked together as cause and effect, which bear no such relation; and, in the other, things which really bear that relation, are perversely dissevered.

Many men pride themselves upon this vicious scepticism, and wish to be thought to exercise a philosophical caution. Voltaire, who was upon the watch for every ludicrous infirmity of human character, was sharp enough to discern this in physicians, and has made excellent sport of it. He makes a physician of renown come from Memphis to cure Zadig of a wound in his *left* eye. The physician, however, affirms it to be incurable, and predicts the very day on which Zadig is to lose his sight, regretting at the same time the accident had not befallen the *right* instead of the left eye, for *then* he would have promised his cure; for that wounds of the *left* eye were in their very nature incurable. But Zadig gets well; and the physician writes a book to prove that he ought nevertheless to have lost his sight.

But much better than the fiction of Voltaire, and very much more to the purpose, is what really happened, and stands authenticated in a Scotch law book. Three physicians and two surgeons made oath in a court of justice, that, "by the rules of their prognostics," the wounds received by one James Houston were mortal wounds. But James Houston was still alive, and, to the honour of the three physicians, the two surgeons, and "the rules of their prognostics," was plaintiff in the very process where they had so memorably deponed*.

With respect to symptoms and their connexion with morbid processes going on within, the subject is too extensive to allow me to enter upon it at present. Indeed, it is so extensive and so important, and so full of its own difficulties, and yet wherein right views are so expedient, and wrong views so perilous, that I have thought it would not be altogether a profitless task both to you and to me, if we were to undertake together a patient and comprehensive examination of this very subject. Therefore, in connexion with the proper business of the wards, and the observation of cases, and (as I trust) for your help and my own, and for our mutual guidance at every step of our practical studies, I will endeavour, in a series of lectures, to give what illustration I am able to the doctrine of symptoms.

It remains that we notice another, and (philosophically considered) a higher purpose, which concerns us in the contemplation of medical facts—viz. the discovery of general principles from them.

A principle (as the name imports) is a beginning. A principle is some matter of fact to which numerous other matters of fact are traced as to a common source; and when we speak of discovering a principle, we mean the business of analysing or decomposing compound matters of fact into those which are simpler, until we come to one which is simpler still, and more general and elementary; and, being unable to go beyond it, we regard this as

* Edin. Med. and Surg. Journal, vol. i. p. 339.

an ultimate fact, or a principle. A principle is an ultimate fact, and a universal fact, and true, without a single contradictory instance.

Now it must be confessed that there is no fact in medicine (*i. e.* no fact respecting the animal body, its actions upon itself, or its obedience to other influences) which has the same character of universality with certain facts respecting the external world. In medicine we have no fact so universal as that all bodies unsupported fall to the ground, no principle so sure or irrefragable as gravitation.

Nevertheless, in medicine we talk of principles, and we are continually striving after them; but, in the strict philosophical sense, have we ever really compassed them?

We have reached *forms* of principles (if I may so say) rather than principles themselves. By *forms* of principles I do not mean things fictitious, or things purely imaginative, but facts tested by observation, and carefully analysed, and very comprehensive, but not universal: facts true in a vast number of instances, but not true in all.

In medicine there have, indeed, been facts, which for a time have passed for universal, and for a time have held the place of principles; but larger experience has shewn that their title to it was not a just one.

There is a certain order of symptoms constituting what is called "angina pectoris;" and angina pectoris was for years, by the common consent of medical men, drawn from extensive observation and dissection, universally ascribed to ossification of the coronary arteries of the heart. But more enlarged experience has found angina pectoris to exist where there has been no such change of structure, but another form of disease, viz. dilatation of the origin of the aorta; and *still* more enlarged experience has found it, where there has been neither one nor the other.

The disease produced by the vaccine virus gave proof, by instances almost innumerable, of imparting to the constitution a protective power against small-pox. Accordingly, this power was believed to be absolute and universal. At length contradictory instances arose and multiplied; and the protective power of vaccination was now no longer a law or a principle. In the present state of our experience we still ascribe to vaccination a protective power against small-pox, but one which is *only highly probable*, not certain. We ascribe to it, moreover, when its protective power fails, a mitigating power; but this, too, is only highly probable, not certain; for assuredly both its protective and its mitigating influence often fail, and small-pox after vaccination goes through all its stages *unaltered*, and is in all respects the *same small-pox*, as when no vaccination has taken place.

After the history of vaccination we know not what number of concurrent instances is enough in medicine to prove a fact universal, or when we can ever be safe against the intervention of contradictory instances, and venture to rely upon any fact as a doctrine or a principle.

But we are not, therefore, to abandon our search after principles; and the same method which in other departments of natural knowledge has alone led to their discovery, we must still employ in ours; for although in our hands a less eminent success has hitherto attended this method, no success whatever has attended any other. This method imperatively requires, that the principle sought be a matter of fact.

If, while we properly restrict ourselves to matters of fact in every other stage of our investigations, we yet take a fiction for our principle, medicine will never improve as a science in our hands, and ancient errors and follies will only give way to new ones.

The fault of physicians has not so much been, that they have shown a general disregard of matters of fact, as that they have lost sight of them just when they ought especially to have kept them in view—when they were concerned with principles. Hence the mischiefs that have arisen to physic in the shape of so many renowned theories, either shown to be false, or not shown to be true. Take any of these false or unverified theories you please, and you will always find it derived from some principle gratuitously assumed, a principle which is either no matter of fact at all, or incapable of being shown to be a matter of fact.

The principle assumed may be some physical process or property, such as a spasm of the extreme vessels, or a peccant matter in the blood; things which possibly may be, but which are entirely without proof, and even too subtle to admit of any; possible facts, but facts quite unascertained and gratuitous.

Or the principle may be neither process nor property, nor any thing that has a physical existence, real or possible, but a mere figment of the mind. The Zoonomia of Dr. Darwin abounds in principles of this kind. Even Mr. Hunter, with all his wariness and penetration in search of truth, admits what he calls "the stimulus of necessity," as a principle or element engaged in the production of diseases before they are yet apparent in their phenomena.

This is to escape from physical inquiry into the region of pure fancy.

What has been said of principles in medicine, whether erroneously or legitimately pursued, may seem to offer small encouragement to physicians to engage further in the search after them. Many of the most celebrated that have given renown to schools and universities, have been abandoned altogether—abandoned because they have been erroneously pursued, and have not possessed the essential character of matter of fact. Many, again, being real matters of fact, and legitimately sought and accepted as principles for a time, have at length been abandoned, because they have been found not to possess the essential character of universality.

But we must still concern ourselves with principles; we cannot help it; all men do it in some sort or other; for the mind is not able constantly to keep in view all the particulars of its own experience. It must needs reduce them within a narrower compass, and contemplate them (so to speak) in some representative. Thus a law or a principle must be set up, right or wrong. Some forge a maxim, and some forge a fact, and soon find it conspicuously illustrated in every instance of disease they meet with. They find *irritation* in every thing, or *spasm* in every thing, or *bile* in every thing. While others, after having gone on observing and collecting facts, and cautiously arranging them according to their natural relations, venture at length to rest in one which seems to have every characteristic of a principle, and yet in process of time may turn out to be no principle at all: witness the protective power of vaccination.

The truth is, something must be conceded to physicians in respect of the very nature of the subject on which they are engaged. Let the principle be ever so legitimately reached, we are only answerable for it as a law explanatory of the facts *already known*. But in medicine new facts are continually presenting themselves. These may be still comprehended within the same principle, or they may not. If they are, they furnish a stronger attestation to its truth. If they are not, they weaken or destroy the principle altogether. But it is no disparagement to us that our principle has failed. We are only concerned that the method by which we reached it is the right one, and then, though it fail, we are at liberty to arrive at a new principle, if we are able, by the same method; that is, to find some other matter of fact comprehensive of the newly discovered particulars, and to concede to it the character of a principle.

Such is the nature of medicine, that things which we have laid up in our minds as settled truths, often require to be modified by our future experience, and come at last to be rated many degrees below the value at which we originally prized them.

Nevertheless, we do not claim for medicine a liberty to transgress any of those landmarks which philosophy has set up to indicate the path of truth. Let it have no other principles, and no other method of arriving at them, but such as philosophy approves; only let no disparagement fall upon it (considering the nature of the things with which it is conversant), if, for just reasons, it be sometimes dissatisfied with principles which it once embraced, and seek to discover new ones.

Finally, then, as to general principles in medicine, let it be remembered that the mind must always seek to arrive at a matter of fact, and *there* only be content to take its rest. But it need not settle there longer than until the clear discernment of some other fact, more general and elementary, opens the way to a safe progression beyond it. Then the fact last discovered becomes the principle, and the other is only one of the several stages conducting to it.

In this mode of proceeding our knowledge may be *incomplete*, but it is never erroneous. The mind advances from fact to fact, resting on one as the stepping-stone to another, and feeling safe in the possession of the truth, although it may not be *all the truth* that is capable of being ascertained.

Every fact from which another fact is derived is in some sort a principle. To us it is a *first* principle as long as we are obliged to rest in it; but as soon as another fact is discovered which is prior to it, it loses its character of a *first* principle; and if it be a principle at all, it is only an *intermediate* one, the first being always that to which we know nothing prior.

ST. GEORGE'S HOSPITAL.

Two Cases of Abscess within the Cranium, discharging through the Ear.

CASE I.—Matthew Palin, ætat. 28, admitted August 24th, 1835, under the care of Mr. Hawkins, and giving the following history of his complaints. Three weeks ago he received a blow on the chest, in a quarrel, and, in attempting to retaliate, he struck his head against the edge of an open door. The blow caused a small wound on the right side of the forehead, with much ecchymosis, though with very

little external hæmorrhage. This caused intense pain in the seat of the blow, which in a few days became more general over the whole forehead. A week after the injury he became delirious, and made repeated attempts to destroy himself. It appeared also, from his wife's account, that he was habitually very low-spirited. Pulse rather quick and small; tongue white, but tolerably moist; slightly delirious, but easily roused from it. Complains of want of sleep, and frowns much, with an expression of much anxiety. It was with some difficulty that he was persuaded to remain in the hospital, on account of the apparently urgent nature of his symptoms.

V. S. ad ℥xii. statim.

Hydrarg. Submur. gr. iss.; Opii, gr. $\frac{1}{4}$. 6tis horis. Tinct. Opii, ♏xv. h. s. s. ex Aquæ Cyatho.

25th.—Blood not inflamed; pulse frequent, with less jerk, and weaker. Pain in the head not at all abated. Slept badly; slight wandering, and great restlessness.

It now appeared, from his own account, that he had been subject, for *some years*, to a discharge from his left ear (which is not, however, now perceptible), on the cessation of which he becomes quite deaf. It could not, however, be ascertained that he had had more pain on this side than on the other since the blow, but still Mr. Hawkins thought it very probable that there was an abscess in the brain, discharging by the ear, as the symptoms were different from those usually produced by suppuration following a recent blow.

℞ Acet. Morphiæ, gr. $\frac{1}{2}$; Carbon. Ammon. gr. v.; Mist. Camph. ℥iss. M. 3tis horis sumend. donec cessaverit dolor. Appl. Emp. Lyttæ Nuchæ. Beef-tea and arrow-root.

26th.—He has passed a better night, and though he says he is not free from pain, yet it is not so great as yesterday. Pulse more perceptible, but labouring. Seems a good deal under the influence of the morphia, of which three doses were given before the pain was relieved.

Cont. Acet. Morphiæ, gr. ss. p. r. n.

27th.—He was restless during the early part of the night, getting out of bed twice, to go to the water-closet; after this he became to a certain extent comatose, and died at 10 o'clock in the morning.

On examination of the seat of the injury there was found no mark of any mischief, either in the bone or its coverings; nor was there any extravasation in the brain. There was no unusual vascularity, and the quantity of fluid in the ventricles was not unusual. On carefully raising the left hemisphere of the cerebrum, it was found to be soft and discoloured, easily lacerable, and partly adherent to the middle fossa at the base of the cranium. In the interior of the middle and anterior lobes was a large abscess, containing about three ounces of foul pus; and the parietes were to some extent soft and green, as if nearly gangrenous. At the bottom of the abscess the brain adhered to the dura mater, covering the thin roof of the tympanum, in the centre of which a small opening in the dura mater allowed a probe to strike on dead bone, about the size of a sixpence; the dura mater to this extent being separate from the bone. With some difficulty a very small aperture was discovered in the dead bone, which allowed a lachrymal probe to enter the cavity of the tympanum, the membrane of which was partially destroyed.

It was thus manifest that he must have had the disease in the brain for a considerable time, the discharge from the abscess occasionally ceasing, as is usual in such cases, producing in him only deafness. The utmost that the blow could have done was to hasten his death, by exciting the abscess already existing. The man with whom he was quarrelling when he ran his own head against the door, is, however, to be tried as the cause of his death, though the only blow which he would seem to have given the deceased was, not on the head, but on the chest.

Case II.—October 2d.—Charles Young, aged 32, cabinet-maker, admitted under the care of Dr. Macleod. Complains of pain in the forehead, particularly above the right eye, extending to the ear and occiput, in which last situation it is extremely severe; has a pretty copious fœtid, thin, puriform discharge from the right meatus auditorius. Pulse 120, very feeble; skin cool and damp; tongue furred, clammy. Bowels much purged (probably from medicine taken before his admission); countenance collapsed; extreme prostration. Ill a month, and attributes the present attack to having sat in a draught after having had his hair cut.

Habeat Haust. Ammoniæ Effervescentem, 4tâ quâque horâ.

℞ Hydrargyri c. Cretâ, gr. v.; Pulv. Ipecac. Comp. gr. iij. M. sum. 8vâ quâque horâ. Broth diet.

3d.—Has rallied considerably; the purging has ceased, and his expression, though still anxious, does not indicate the same excessive exhaustion. Pulse 98, with more

power, but still very compressible. Discharge from the ear continues, and it now appears, from the testimony of his wife, that he has had it occasionally for about two years.

Dr. Macleod stated it to be his opinion that the discharge from the external ear originated in an abscess within the cranium, and that the patient would die.

Emplast. Lyttæ pone aurem dextram.
Rep. Hydrarg. c. Creta. Omitt. alia.

5th. — Pain of head considerably relieved, which he attributes to the blister. Has been rather drowsy this morning, but says this is owing to his being comparatively free from pain. Pulse 84, soft; tongue retains its fur, and the bowels did not act yesterday, nor have they done so to day.

Sumatur Haust. Sennæ quamprimum et repetatur quartâ quâque horâ donec responderit alvus; dein repetatur Hydrarg. c. Creta, ut antea.

6th.—Bowels freely opened by the first draught. Drowsiness continued during the whole of yesterday. In the evening he was attacked with pain, extending all over the right side of the head; for which ten leeches were applied to the temple with some relief. Gums sore.

Omitt. Hydrar. c. Creta. Habeat. Haust. Salin. 4tis horis.

7th. — Still complains of considerable pain in occiput and over right eye; is in a state of partial stupor; brows knit, and expression anxious; right eye particularly dull, but he sees distinctly with it; pulse 84, large; tongue dry and furred; urine scanty, and voided with difficulty.

Hirudines xiv. tempori dextro. Rep. Haustus.

8th.—Stupor increases; pulse 64, large and soft; bowels sluggish; urine still rather scanty; ptyalism receding; discharge from ear less abundant.

Haust. Sennæ, quamprimum; Calomel, gr. ii. 4ta quâque horâ. Emplast. Lyttæ Nuchæ.

9th. — Comatose; pulse 58; bowels have not acted; gums again becoming sore.

℞ Ol. Terebinth. ℥i.; Enematis Domestici, ℥vi. M. fiat Enem. quamprimum injiciendum.

Rep. Haust. Sennæ et Calomelas.

11th. — Gradually sank, and died at 1 P.M.

Autopsy, October 12th.—*Head.* Cerebrum and its investing membranes perfectly healthy; about an ounce of colourless fluid in the ventricles. Cerebellum, at the lower and anterior surface on right side, exhibited a spot of greenish colour, and size of a sixpence; in its centre was an aperture, sufficient to admit a small probe. This perforated the dura mater, and led into an abscess in the cerebellum, which, being laid open by a horizontal section, was found to be about the size of a very large walnut flattened; it contained dirty-looking, greenish, fœtid pus; and the parietes were of a similar appearance, but greater consistence, about a line in thickness, and gradually blending with the surrounding substance of the cerebellum. In the vicinity of the abscess were a few minute spots of extravasated blood. The aperture in the dura mater presented opposite to a corresponding perforation in the pars petrosa of the temporal bone, and leading into the internal ear, which was disorganised, and allowed the matter to flow by the external meatus. No other diseased appearance was found.

The cerebellum and corresponding portion of bone have been preserved in the museum of the hospital, and a drawing made of them by Dr. Hope.

Instances like the above, in which abscesses within the cranium communicate with the ear, are by no means very uncommon; and it is therefore of importance that we should keep in mind the necessity of a guarded prognosis in such cases. It has generally been assumed that the disease originates in the ear, and spreads to the parts within the cranium; but this is by no means well ascertained, and some of the circumstances would rather lead us to believe that the disease travelled in an opposite direction. We allude particularly to the fact that those cases in which the ear is unequivocally the primary seat of disease (as from cold, from the inflammation spreading along the Eustachian tube in scarlatina, or from foreign bodies irritating the external meatus), we very seldom hear of the brain becoming affected in this manner, although the internal ear may be so much disorganised as to produce permanent deafness.

ST. BARTHOLOMEW'S HOSPITAL.

Fibrous Tumor connected with the lower Jaw—Removal of the left half of the Jaw.

The operation of removing the left half of the lower jaw was performed by Mr. Stanley, on Saturday, the 10th instant. The following is a report of the case at the time of admission.

A. B., a girl aged 15. She states that the disease has been twelve months in progress, and that it has not been attended with pain, or disturbance of the general health. A tumor now occupies the whole of the left side of the jaw, from the angle to within half an inch of the symphysis. The length of the tumor, therefore, corresponds with this extent of the jaw, and in its broadest part it measures a full inch and a half. The tumor is but little apparent on the outside of the face; its principal growth having taken place towards the cavity of the mouth: it is smooth, and does not yield to the firmest pressure; its upper surface is slightly ulcerated. The absorbent glands and other parts in its neighbourhood are healthy. In an early stage of the disease, with the idea that the tumor contained fluid, a lancet was plunged into it; this was followed by a considerable flow of blood, but had no other effect. With the gradual increase of the tumor, the fangs of the teeth were successively imbedded in it. Mr. Stanley had removed several of these loosened teeth, and by introducing a probe into the centre of the tumor, had ascertained it to be a growth from the cancellous texture of the jaw. Before the admission of the patient into the hospital, Mr. Stanley had tried iodine freely for a fortnight, both as a local application and internally, but it had no influence upon the disease, which was still slowly increasing, and accordingly its removal was undertaken.

An incision commencing an inch in front of the extremity of the lobulus of the ear was continued in a semicircular line downwards and forwards over the base of the jaw, and then upwards upon the chin to within about an inch of the orifice of the mouth. The division of the cheek was followed by the detachment of all the contiguous parts from the tumor, and by the exposure of the jaw beyond it sufficiently to permit the division of the sound part of the bone. With a small saw a groove was made in the jaw close to the symphysis, and with the large cutting forceps the division of the bone was here completed. With the forceps alone the division of the ramus of the jaw was easily effected a little above the angle; it now only remained to divide the mucous membrane of the mouth where it was continued upon the inner side of the tumor. Very little hæmorrhage had occurred, only two arteries requiring to be tied, the facial and one of its branches. The divided surfaces of the cheek were retained in contact by hare-lip pins and fine silk ligatures. Scarcely any constitutional derangement followed the operation. The whole tract of the wound united by the first intention; and on the eighth day the patient, in good health, had left her bed, and was moving about the ward. The cicatrix being a mere line, occasions but the slightest disfigurement of the face. There is no falling inwards of the cheek. The articulation is perfect, and already the muscles can act upon the remaining half of the jaw with so much force, that with a little more use of the parts, she will be able to masticate the firmest substances.

Upon examination, the tumor was found to have originated in the cancellous texture of the jaw, and in its progress, to have caused, first the expansion and then the partial absorption of the walls of the bone, some portions of which still contribute to form the boundaries of the tumor. The section of the tumor shewed that it consisted throughout of a dense greyish substance, irregularly intersected by white lines. In its colour and texture, this specimen of morbid growth from the jaw closely resembles the common fibrous tumor of the uterus.

Mr. Stanley stated that every circumstance in the history of the disease indicates that it is not of a malignant nature.

ELECTION TO THE COUNCIL OF THE COLLEGE OF SURGEONS.

APPEAL OF MR. KINGDON.

To the Editor of the Medical Gazette.

Sir,

Will you have the goodness to grant insertion of the accompanying letter in your journal of next Saturday, and oblige,

Sir,

Your very obedient servant,

W. Kingdon.

2, New Bank Buildings,

To the Medical Profession.

Gentlemen,—Having of late been treated with injustice by the *majority* of the Council of the College of Surgeons, and having learnt that he who tacitly submits to injustice becomes an instrument to his own degradation, I take this, I believe the most proper, method to protest against the measure of exclusion which has been practised towards me. Thinking that such a body would not willingly treat any one with injustice, I suspected there must have been, unknown to me, some disparaging report abroad, and therefore addressed the

President and Council, to inquire if, to the belief of any of them, such report existed.

After some time, I received an answer, avoiding the question; and thus, in effect, admitting that if they allowed me an unsullied reputation they damnified their own conduct. On the same showing, however, their conduct was calculated to damnify my fair fame, more valued and estimated by me, as more essential than life itself to the well-doing, both present and future, of myself and family. Without power to question this conduct, shielded as it is by charter, granted (we may presume) by a gracious Sovereign, for the benefit, and not the oppression, of his subjects, I still have the power possessed by every English gentleman, to see that my reputation do not suffer by the selfish or partial conduct of others; and it is for this reason that I now address my professional brethren. After more than twenty years of public and private practice as a surgeon in London, I must be known to some of you, and I address you to entreat that if any of you know, or think you know, any thing disparaging to my character, you will have the goodness to inform me, and thus confer the greatest favour that it is possible for man to confer on man; for I am conscious that any such disparagement need only be made known, to be proved as resting on misapprehenson or founded on falsehood. Having avoided all legal ineligibility to a seat at the Council of my College, the exclusion would seem to imply that I have by some act, either professional or otherwise, rendered myself unfit for election.

Unless erroneous information respecting me, given to the Parliamentary Committee by the then President of the College (which he afterwards made all endeavours to correct that gentlemanly feeling could prompt), has been deemed a sufficient cause to throw me out of my fair professional course,—or unless my not having an interest in common with surgeons of hospitals, or a mind easily led to surrender its own views, and see things as others wish,—be deemed a sufficient cause, (and neither of these can be supposed to influence the minds of honourable men), I must remain under the stigma of exclusion for my own demerit, did I not make this appeal to my professional brethren, so as to make known to them that on the majority of the Council rests the responsibility of having used their power unjustly. Such conduct needs only to be canvassed for the reprobation of the right-thinking to fall on those who practise it; and I have felt it my duty to offer my character for the strictest investigation, in order that the *majority* of the Council may have the benefit, if any thing can be found against it, as an excuse for their unprofessional and unjust conduct. It is the conduct of such men that drives the quiet and the peace-lover to desire and enforce change. It is the conduct of such men that renders futile the best efforts of the honourable and the able to place the affairs of our country on a footing of fairness and stability.

I am, gentlemen,
Very faithfully yours,
W. Kingdon.

ROYAL COLLEGE OF SURGEONS.

Mr. J. H. Green has been elected a member of the Council of the College, in the room of Sir W. Blizard, deceased.

TIEDEMANN.

This very distinguished physiologist, after a sojourn of about two months in this country, left London on Saturday last to return to Heidelberg. We are glad to learn that previous to his departure he sat for his portrait to an eminent artist, and that a striking likeness of him has been taken. Mr. Schloss, we understand, will shortly publish a lithographic copy of the portrait.

WEEKLY ACCOUNT OF BURIALS.

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE VI.

GENTLEMEN,—The subject of this day's lecture is pharmacological classification.

Writers on medical botany frequently follow no order in treating of plants used in medicine. I may refer you to the works of Woodville, of Stephenson and Churchill, of Bigelow, and of Barton, as examples. The difficulty of procuring botanical specimens in regular succession is the only excuse that can be offered for this mode of proceeding.

The substances employed in the treatment of diseases being very numerous, I conceive any kind of arrangement of them is better than none. The principles on which authors have proceeded in effecting pharmacological classifications are very different: some have arranged medicines alphabetically; others according to their physical, natural-historical, chemical, or medicinal qualities. We may very conveniently make two classes of these arrangements:—

Class I.—Including those which we may term *empirical.*

Class II.—Those which we may, in contradistinction, call *rational.*

CLASS I.—By *empirical* arrangements I mean those founded on circumstances which have no real relation or connexion with the substances to be arranged, and which, therefore, are independent of the nature of these bodies. For example, an *alphabetical* order is empirical, since it is founded on names, which are arbitrary, and have no real relation to the substances they are used to designate. A considerable number of pharmacologists, both English and Foreign, have adopted this method, by which it was supposed two advantages were gained—namely, a ready reference to any particular subject; and secondly, an avoidance of errors committed by all writers who adopt other methods.

But I think it will not be very difficult to demonstrate that no peculiar advantage is gained by it. In the first place, the ready reference is more imaginary than real; for every substance is known by more than one name, and hence an index becomes as necessary to this as to any other arrangement; in proof of which I may refer to the Dispensatories of Duncan and Thomson, both of which, though arranged alphabetically, have their indexes. Now an index gives us every advantage of an alphabetical arrangement, and therefore, if appended to any other modes of classification, renders the latter as convenient for reference as the former. Secondly, the alphabetical order has also its disadvantages. The most important are, that it brings together substances of the most incongruous natures, and separates those which accord in most of their properties; in addition to which, it is totally unfit for an elementary work, since, by its want of order, it distracts the attention of the student.

The following are some of the authors who have adopted it:—

1. *In England.*—Lewis, Paris, Brande, Ainslie, A. T. Thomson (Dispensatory), and Duncan.

2. *In France.*—Bodard, Hipp. Cloquet (Faune), Chevallier, Richard and Guillemin (Dict.), Martinet, Ratier, and Merat and De Lens (Dict.)

3. *In Germany.*—Jahn, Horn, Schmidts, Hahnemann, Segniss, Hartlaubs and Trinks, and Dulk.

Class II.—By *rational arrangements* I mean those having some connexion with the bodies to which they are applied, and which are founded on some of their properties; they are the classifications properly so called. Being, then, founded on the qualities of the bodies to be arranged, they must necessarily be as various as there are classes of properties. Now a medicine has sensible properties (such as colour, taste, and smell); it has natural-historical properties (external form and structure); chemical properties; and lastly, it excites certain alterations in the functions of the body, for which we employ it medicinally. Rational arrangements, therefore, may be physical or sensible, natural-historical, chemical, or physiological. Let us, then, take a general view of each of these.

I. *Classifications founded on the sensible properties of the materia medica* are to a certain extent useful, though I have already shown you that these properties give us very little information regarding the effects which different substances produce on the system. The latest and best arrangements of this kind are, one by Dr. Osborne, in the fifth volume of the Transactions of the Association of the Fellows and Licentiates of the King and Queen's College of Physicians; and one by Mr. A. F. A. Greeves, to which the prize was awarded in the class of materia medica in the University of Edinburgh; it was published by the late Dr. Duncan, in the Supplement to the Edinburgh New Dispensatory, and is certainly the best of the kind I have seen. The following is a tabular view of it:—

Mr. Greeve's Classification.

Classes.	Families.	Orders.
I. Inodorous and insipid	1. Liquid	1.
	2. Soft	1. Pulverescent. 2. Unctuous.
	3. Hard	1. Tough. 2. Brittle.
II. Inodorous and sapid	1. Sweets	1. Saccharineæ. 2. Amylaceous. 3. Mucous or Unctuous. 4. Faint. 5. Frugous.
	2. Bitters	1. Mawkish. 2. Astringent. 3. Pure bitter. 4. Austere. 5. Styptic. 6. Acrid. 7. Salino-amaræ.
	3. Alkalines	1.
	4. Acids	1. Pure acid. 2. Saccharo acid.
	5. Salines	1. Pure salt.
III. Odorous and insipid	1. Fragrant	1. Sweet. 2. Aromatic.
IV. Odorous and sapid	1. Sweets	1. Saccharineæ. 2. Faint. 3. Sweet spicy.
	2. Bitters	1. Mawkish. 2. Subastringent. 3. Bitter spicy. 4. Sharp bitter. 5. Austere. 6. Subacrid. 7. Acrid.
	3. Aciduous	1.
	4. Camphreous	1. Camphreous aromatics. 2. Savoury. 3. Terebinthinatæ. 4. Camphreous.
	5. Spirituous	1. Vinous. 2.

II. *Natural-historical classifications* are much more useful than those already mentioned; yet they are open to several objections, of which the principal are the following:—In some instances substances of dissimilar operation are brought together, while others are separated whose effects are very analogous; and, as the ultimate object of all our inquiries into the materia medica is to obtain a knowledge of the medicinal effects, a natural-historical arrangement, it may be said, offers inferior advantages when compared with a classification founded on the operation of medicines. Notwithstanding these objections, I think it is by far the best method for lectures, and is the one which I shall adopt. Without asserting, or pretending to assert, that this is without real and solid objections, yet I cannot help thinking there are much more weighty reasons against other modes of arrangement than against this. I believe, also, that the principles on which natural-historical classifications are founded are such, that these arrangements have attained a greater degree of perfection. Added to which, other reasons render this mode preferable in lectures, but which, perhaps, do not equally apply to writings: I allude to the variety of interesting points of natural history which it allows us to introduce; added to which, we avoid the inconvenience arising from having to speak of the same substance several times under different heads. These circumstances have led me to adopt the natural method in these lectures. I shall, therefore, on the present occasion, enter into no details respecting it, as the principles of this arrangement will be fully discussed hereafter. I regret that, with the exception of a little work by Dr. Johnstone, of Birmingham, all the books to which I can refer you wherein this method has been followed are Foreign. The following are some of the best:—

1. *French.*—The works of De Candolle, Fee, De Smyttère, and Richard.

2. *Germans.*—The publications of J. A. Murray, Gmelin, Tode, Cassel, Kapp, Nees von Esenbeck, Dierbach, and Brandt and Ratzburg.

III. I must next direct your attention to *chemical classifications*, which are employed by some of the German pharmacologists; for, with the exception of Donald Monro's work, I know of no systematic work, either French or English, in which this method has been followed. In fact, these arrangements, although of value to the chemist, are of little use to the medical practitioner. This, I believe, principally arises from the difficulties and uncertainties experienced in the analysis of organic substances; for, as I have already remarked, the chemical properties of bodies give us very little insight into their physiological effects. No one, for example, could suspect, from chemical analysis, the poisonous property of the virus of the viper, or of the mad dog. I conceive, also, the establishment of the doctrine of *isomerism*, that identity of composition is not always attended with identity of properties, will diminish still more the value of chemical classifications. The following are some of the German writers who adopt this mode of arrangement:—Klose, Pfaff, Gren, Voigtel, Hufeland, Hecker, Schwartz, Richter, Hoffman, and Bischoff.

As an example of a chemical arrangement, I shall select that adopted by Schwartze, in his *Pharmacologischen Tabellen.*

Schwartze's Classification.

DIV.

1. Aqua communis.
2. Gummosa, mucilaginosa.
3. Farinosa, amylacea.
4. Gelatinosa.
5. Albuminosa.
6. Saccharina.
7. Pinguia—Oleosa.
8. Extractiva amara.
9. Adstringentia seu Tannica.
10.Ætherea—Oleosa.
11. Resinosa.
12. Narcotica.
13. Spirituosa.
14. Acida.
15. Alcalina.
16. Salina.
17. Metallica.
18. Corpora simplicia, solida, non metallica.
19. Kalia sulphurata.
20. Sapones.

You will observe that the author has not always founded his divisions on the chemical properties of medicines; some of them refer partly or wholly to the effects produced by these agents on the body. The nomenclature is not always perfect: thus, his seventeenth class is called "metallica," as if it alone contained metallic substances; whereas division sixteen and seventeen also contain them. Again, some of the divisions, for example "resinosa," contain substances whose effects are most dissimilar; while substances of analogous operation are placed in separate divisions.

One of the latest writers on the materia medica among the Germans, is Dr. C. H. E. Bischoff, who has published an extensive work, entitled "*Die Lehre von den Chemischen Heilmitteln oder Handbuch der Arzneimittellehre.*" He has arranged the articles according to their supposed chemical, or rather electro chemical, properties. The following is a tabular view of his arrangement:—

Class I.—Negatively electrical medicines of basic quality.

Orders.

1. Gas hydrogenium.
2. Oleum æthereum animale.
3. Ætheres et acida dulcificata.
4. Alkohol.
5. Ammonium.
6. Ammonium sulphuratum.
7. Gas hydrogenium sulphuratum.
8. Gas azoticum oxydulatum.
9. Oleum æthereum vegetabile.
10. Camphora et anemonin.
11. Oleum æthereum empyreumaticum animale.

Class II.—Indifferently electrical medicines of neutral quality.

Orders.

1. Acidum hydrocyanicum.
2. Narcotica fixa.
3. Acrid.
4. Sulphur.
5. Metalla cyanata, sulphurata, oxygenata, atque salita.
6. Iodeum, iodeum hydrogenatum, salia hydriodica et cyanatum.
7. Pinguedo, [*Fett.*]
8. Resina.
9. Gelatina.
10. Albumen.
11. Mucus, [*Schleim.*]
12. Farina et fecula farinæ.
13. Saccharum.

Class III.—Positively electrical medicines of acid quality.

Orders.

1. Acidum aromaticum.
2. Materies extractiva.
3. Tannicum.
4. Carbo.
5. Acida composita (vegetabilia) et salia neutra.
6. Aquæ soteriæ acidulæ.
7. Acida mineralia.
8. Medicamina halogenia eorumque acida et salia cum aquis soteriis muriaticis.
9. Aquæ soteriæ martiales, ferrum et plumbago.
10. Oxygenium.

This classification is objectionable even on chemical grounds. Sulphuretted hydrogen is not a *basic*, but an acid body; hydrocyanic acid is not *neutral*. The orders 2 and 3 of class the second are not founded on the chemical properties of the substances. These are only a few of the errors pervading this arrangement.

IV. I now come to *physiological classifications*, which, in theory, I hold to be the best of all; but in practice, far inferior to the natural-historical: that is, I think we have at present too limited an acquaintance with the effects of medicines, to enable us to form any classification founded on them which can be either correct or of much value. Every writer who has attempted to form one, has been obliged to introduce theory; and, therefore, we find the so-called physiological arrangements are really founded on the prevailing doctrines of the day, to all the errors and fallacies of which they are liable. Thus, Dr. John Murray, Oberreich, Chortet, Müller, Schöne, and others, adopt the Brunonian doctrine, that all medicines are stimulants; and hence the very basis of their arrangement is hypothetical. Another class of writers assume that there are two, and only two, classes of medicines—stimulants and contra-stimulants; or stimulants and asthenics. Here, again, we have hypothesis. By some writers—Barbier, for example—the operation of all medicines is assumed to depend on their chemical properties; by others, the very reverse assumption is made, and a class of substances is admitted under the name of vital agents, supposed to act independently of their chemical properties. Barbier asserts that laxatives relax (as their name implies); while the followers of Broussais assert they irritate. At one period medicines were presumed to act both on the solids and the fluids. Subsequently this was denied, and the operation of all was referred to the solids. Yet, as I have before stated, we have just as good grounds for believing that some agents primarily alter the quality of the blood, as to suppose that they act on the solids. Thus, then, you see there are many points yet unsettled which require to be known ere a correct physiological classification can be expected.

In a course of lectures, I conceive other objections exist to the adoption of an arrangement of this kind. Most medicines produce several effects, and we should be obliged to speak of the same remedy under several heads; for example, squills being emetic, diuretic, and expectorant, would require to be brought three distinct times under examination, which, to say the least of it, would be an inconvenience. Again, substances are often associated to form a class, in consequence of their agreeing in one or more effects, whose general operation, however, is very different. Thus, foxglove, squills, urea, and nitre, are all diuretics, yet their general action on the system is very different.

The following are some of the writers who have adopted this mode of arrangement:—

1. *In England*—Cullen, Pearson, Young, Murray, Duncan, A. T. Thomson, and Johnstone.

2. *In France*—Vitet, Chortet, Menard, Schwilgué, Barbier, Alibert, Edwards and Vavasseur, and Foy.
3. *In Germany*—Sift, Gesenius, Monch, Frank, Oberreich, Müller, Neurohr, Schöne, Hartmann, Arnemann, Hermann, Pachur, Sundelin, Vogt, Wendt, &c.
4. *In America*—Eberle, and Chapman.

There are two modes of classifying medicines according to their effects; the first is to place together all those substances which concur in affecting a particular organ or structure; the second is to group medicines according to the quality of their effects. For example, when we make a class of "substances acting on the nervous system," we adopt the first method; whereas, if we form a class of "narcotics," we follow the second. The classification of Alibert belongs to the first method.

Alibert's Classification.

I. Medicines acting in a special manner on the vital properties of the digestive passages.

1. Medicines acting in a special manner on the tonicity or fibrillary contractility of the system of the digestive passages. [*This includes tonics.*]
2. Medicines acting in a special manner on motility or muscular contractility of the system of the digestive passages. [*Here are placed emetics and purgatives.*]
3. Medicines proper for combating the alterations of the vital forces which result from the presence of worms, or of poisons in the digestive passages in the stomach or in the intestinal canal. [*Anthelmintics and antidotes.*]
4. Medicines acting in a special manner on the vital properties of the large intestines. [*Enemata.*]

II.—Medicines acting on the vital properties of the urinary passages. [*Including diuretics.*]

1. Medicines acting in a direct or special manner on the vital properties of the urinary passages.
2. Medicines acting in an indirect or sympathetic manner on the vital properties of the urinary passages.

III.—Medicines acting in a special manner on the vital properties of the system of respiration.

1. Medicines acting in a special manner on the vital properties of the system of respiration, to free it from the superabundant matters which oppress it. [*Expectorants.*]
2. Medicines acting in a special manner on the vital properties of the system of respiration, by the aid of pneumatic apparatus.
3. Medicines acting in a special manner on the vital properties of the system of respiration, when their exercise is suspended by the phenomena of asphyxia.
4. Medicines acting in a special manner on the vital properties of the system of respiration, to moderate the excess of animal heat. [*Refrigerants.*]

IV.—Curative means specially directed to the vital properties of the system of circulation.

1. Curative means specially directed to the vital properties of the circulation of black blood. [*Phlebotomy, leeches, and scarifications.*]
2. Curative means specially directed to the vital properties of the circulation of red blood. [*Arteriotomy.*]

V.—Medicines acting in a special manner to the vital properties of the brain and nervous system. [*Narcotics.*]

VI.—Medicines acting in a special manner on the vital properties of the sensitive organs.

1. Of the organ of vision.
2. Of the organ of hearing.
3. Of the organ of smell. [*Errhines and sternutatories.*]
4. Of the organ of taste. [*Sialogogues and masticatories.*]

VII.—Medicines acting in a special manner on the vital properties of the tegumentary system.

1. Considered as an organ of absorption. [*Iatraleptic medicine.*]
2. Considered as an exhalent organ. [*Diaphoretica.*]
3. Considered as a sensible organ. [*Epispastics, electricity, animal magnetism, acupuncture, baths, &c.*]

VIII.—Medicines acting in a special manner on the vital properties of the productive system.

1. Of the male genital apparatus. [*Aphrodisiacs.*]
2. Of the female genital apparatus. [*Emmenagogues.*]

Dr. Osann has given an example of a similar mode of classification in the "*Encyclopädisches Wörterbuch der Medicinischen Wissenschaften.*"

In 1822, Dr. Granville proposed a new classification of the Materia Medica; the primary divisions being founded on the tendency which medicines have to affect particular organs or systems of structure, while the subdivisions are formed from the *quality* of the effect. This plan formed the ground-work of the classification adopted by Dr. Eberle, an American writer, in his "*Treatise of the Materia Medica,*" published in 1824.

Eberle's Classification.

A.—Medicines that act specifically on the intestinal canal, or upon morbific matter lodged in it	I. Medicines that excite discharges from the alimentary canal	Emetics. Cathartics.
	II. Medicines calculated to destroy or counteract the influence of morbific substances lodged in the alimentary canal	Anthelmintics. Antacids.
B.—Medicines whose action is principally directed to the muscular system	I. Medicines calculated to correct certain morbid conditions of the system, by acting on the tonicity of the muscular fibre	Tonics.
	II. Medicines calculated to correct certain morbid states of the system, by acting on the contractility of the muscular fibre	Astringents.
C.—Medicines that act specifically on the uterine system	I. Medicines calculated to promote the menstrual discharge	Emmenagogues.
	II. Medicines calculated to increase the parturient efforts of the womb	Abortiva.
D.—Medicines that act specifically on the uterine system	I. Medicines that lessen the sensibility and irritability of the nervous system	Narcotics.
	II. Medicines that inecase and equalize the nervous energy	Antispasmodics.
E.—Medicines whose action is principally manifested in the circulatory system	I. Medicines that increase the action of the heart and arteries	Stimulants.
F.—Medicines acting specifically upon the organs of secretion	I. Medicines that act on the cutaneous exhalents .. General ..	Diaphoretics.
	I. Medicines that act on the cutaneous exhalents .. Topical ..	Epispastics. Errhines. Emollients.
	II. Medicines that increase the action of the urinary organs	Diuretics.
	III. Medicines that alter the state of the urinary secretion	Antilithics.
	IV. Medicines that promote the secretory action of the salivary glands	Sialagogues.
G.—Medicines that act specifically upon the respiratory organs	I. Medicines calculated to increase the mucous secretion in the bronchia, and to promote its discharge	Expectorants. Inhalations.
	II. Medicines whose action is truly topical	Emollients. Escharotics.

Notwithstanding that several of its details are objectionable, the plan of this classification appears to me an exceedingly good one.

I proceed, in the next place, to examine those arrangements, the basis of which depends on the quality of the effects produced: locality of operation being a secondary consideration. The number of these which have been proposed within the last few years is so great, that were I to attempt to take a general review of all of them, I conceive I should be very unprofitably consuming your time; as I should have to devote a considerable portion of this course of lectures to the subject. I propose, therefore, to confine my remarks to one or two of the leading classifications of England, France, and Germany; beginning with that of the late Dr. John Murray, which, with a few alterations, might, I conceive, still be unrivalled for its practical value and simplicity.

Murray's Classification.

A. General Stimulants :—

- (a) *Diffusible* — Narcotics. Antispasmodics.
- (b) *Permanent* — Tonics. Astringents.

B. Local Stimulants :—

Emetics.
Cathartics.
Emmenagogues.
Diuretics.
Diaphoretics.
Expectorants.
Sialogogues.
Errhines.
Epispastics.

C. Chemical Remedies :—

Refrigerants.
Antacids.
Lithontriptics.
Escharotics.

D. Mechanical Remedies:—
Anthelmintics.
Demulcents.
Diluents.
Emollients.

The principal objections to this arrangement are the following:—1st. The general operation of medicines is assumed to be stimulant; of which we have no proof in the case of hydrocyanic acid, of foxglove, or of tobacco. 2dly. The distinction into general and local stimulants is bad; for narcotics are unquestionably in their primary operation, local agents; and drastic purgatives, emetics, &c. when given in full doses, affect the general system. 3dly. The terms antispasmodic, antacid, lithontriptic, and anthelmintic, refer to the therapeutic, and not to the physiological effects of medicine. 4thly. It is an assumption to say that refrigerants are chemical remedies. 5thly, emollients are not mere mechanical agents.

The classification proposed by the late Dr. Duncan is, in many respects, an improvement of that of Murray.

Duncan's Classification.

External agents act,

1. By nourishing the body—Alimenta.
   (*a*) Drink—*Potus.*
   When they act medicinally—*Diluentia.*
   (*b*) Food—*Cibi.*
   When they act medicinally—*Demulcentia.*
2. By evacuation—Evacuantia.
   (*a*) By the skin insensibly—*Diaphoretica.*
   ———— sensibly—*Sudorifica.*
   (*b*) By the mucous membrane of the nostrils—*Errhina.*
   By the mucous membrane of the lungs—*Expectorantia.*
   By the mucous membrane of the stomach—*Emetica.*
   By the mucous membrane of the intestines—*Cathartica.*
   By the mucous membrane of the uterus—*Emmenagoga.*
   (*c*) By glandular secretion:
   The kidneys—*Diuretica.*
   The salivary glands—*Sialogoga.*
3. By exciting the vital powers—Stimulantia.
   (*a*) Chiefly of the parts to which they are applied—Topica.
   Applied externally,
   Causing redness—*Rubefacientia.*
   ——— serous secretion — *Vesicantia.*
   ——— purulent secretion—*Suppurantia.*
   Administered internally,
   Condimenta, when alimentary.
   When acting medicinally—*Carminativa.*
   (*b*) Of the system generally—Generalia.
   (*α*) Obscurely, but more durably—Permanentia.
   Producing no immediate effect—*Tonica.*
   Constricting fibres, and coagulating fluids—*Astringentia.*
   (*β*) More evidently, but less durably—Transitoria.
   Acting on the organic functions —*Calefacientia.*
   Acting on the mental functions —*Inebrientia.*
4. By depressing the vital powers—Deprimentia.
   Acting on the organic fuctions—*Refrigerantia*
   Acting on the mental functions—*Narcotica.*
5. By chemical influence on the fluids—Chemica.
   Acidifying—*Acida.*
   Alkalizing—*Alkalia.*

Like every other physiological arrangement proposed, this has its objections. In the first place, a distinction of classes is sometimes made without much difference; for example, diaphoretica and sudorifica; also the rubefacientia, vesicantia, and suppurantia; and to these we may add the calefacientia and carminativa. Nux vomica cannot be said either to depress the general system or to act on the mental functions: yet Dr. Duncan classes it among the narcotica. Opium is sometimes used to inebriate, as by the Turks; at other times to cause sleep. In the first case it would, by this classification, be considered as an excitant, and placed among the inebriants; whereas, in the second case, it would be presumed to depress, and therefore be ranked among the narcotics.

Dr. A. T. Thomson has, in his "*Elements of Materia Medica*," offered a classification for the most part founded on that of Dr. Murray, but freed from some of the objections to which I have already stated the latter is liable. Thus, in place of making the two divisions, general and local stimulants, he makes only one; which he calls, after Dr. Young, "vital agents."

These are all the physiological classifications proposed in this country, which I think it necessary to notice.

Barbier, one of the leading pharmacological writers of France, has offered the following arrangement:—

Barbier's Classification.

		Classes.
Medicines	which strengthen the tissue of organs	1. Tonics.
	which stimulate the tissue of organs	2. Excitants. 3. Diffusibles.
	which relax the tissue of organs	4. Emollients.
	which moderate the too great activity of organs	5. Temperants.
	which diminish cerebral life	6. Narcotics.
	which irritate the internal surface of the intestines	7. Purgatives.
	which irritate especially the gastro-duodenal surface	8. Emetics.
	which disorder the natural movements of the intestines,	9. Laxatives.
	whose action is not well determined, or which cannot be referred to any of the preceding classes	10. *Incertæ sedis.*

There are several parts of this classification which appear to me objectionable. Some substances called narcotics do not, under all circumstances, diminish the activity of the cerebral functions; on the contrary, in moderate doses, they occasionally have an opposite effect. I do not think it expedient, or proper, to separate purgatives and laxatives; and I conceive that several of the substances inserted under the head of *incertæ sedis*, might, with great propriety, be placed in some of the preceding classes.

The next classification which I propose to bring under your notice is that of a German physician, Dr. Vogt, the author of an exceedingly good work, entitled *Lehrbuch der Pharmakodynamik*. I regret, however, that I cannot say much in favour of his classification. He makes three classes; the first including those agents which specially affect the *sensibility* of the body, the second containing those which alter the *irritability* of the system, and the third embracing those agents which influence what he calls the *vegetation* of the body—that is, the organic functions; namely, nutrition and reproduction. The following is a tabular view of the classes, and their principal subdivisions:—

Vogt's Classification.

	Orders.	Divisions.
Class 1. Medicines operating specially on the nervous system, and particularly used as nervous agents	1. Medicines which limit the vital manifestation of the nervous system (*Narcotica*)	1. Opium and its allies. 2. Nux vomica, and medicines similar to it. 3. Hydrocyanic acid, and vegetables allied to it. 4. Belladonna, and medicines similar to it.
	2. Medicines which exalt and strengthen the vital manifestations of the nervous system (*Nervina*)	1. Nervinia volatilia (ammonia, musk, &c.) 2. Nervino-alterantia antispasmodica (ipecacuanha, copper, zinc, bismuth, &c.)
Class 2. Medicines operating specially on irritable life [*auf das irritable Leben*]	1. Weakening (*Antiphlogistica*), as the neutral salts, cold, &c.	
	2. Medicines which heighten and strengthen the vital manifestations of the irritable system.	1. Excitantia volatilia (as camphor, mints, &c.) 2. Tonica. 3. Antiseptica (acids, chlorine, &c.)
Class 3. Medicines operating specially on the vegetative [organic] system, and which are particularly used in diseases of vegetation [nutrition and reproduction]	1. Medicines operating specially on the secreting and excreting systems	1. Heat. 2. Gummi—resinosa, balsamica, and resinosa. 3. Resolventia (acrids, mercury, antimony, sulphur, alkalies, iodine, &c.)
	2. Medicines which specially operate on the formative process.	1. Aromata (pepper, pyrethrum, nutmegs, &c.) 2. Nutrientia.

You will observe that the author does not confine his orders to those drawn from physiological effects, but constitutes some (antiphlogistica and antiseptica) which have a direct reference to disease.

These, however, are not the sole objec-

tion to this arrangement. When we come to examine the division of his orders, we feel astonished that an intelligent writer like Vogt should huddle substances of such different properties (as aconite, ergot of rye, croton oil, cantharides, squills, mercury, antimony, sulphur, alkalies, iodine, &c.) into one subdivision, under the very objectionable term *resolventia*. In its common acceptation this word signifies local agents applied to remove enlargements supposed to depend on obstruction. It refers, therefore, evidently to hypothetical conditions, and has no direct connexion with physiological effects.

On the other hand, we find substances whose effects are somewhat analogous, placed in different parts of the classication. Take the following as examples: belladonna and stramonium are placed under narcotica, while aconite and conium are classed among resolventia. Ammonia, musk, and castoreum, are called nervinia volatilia, and placed among substances exerting a specific influence over the nervous system; while camphor, alcohol, and æther, belong to the excitantia volatilia; rosemary is called narcotic; the mints volatile excitants.

I do not think it necessary, gentlemen, to bring before you any further examples of classifications of the articles of materia medica, founded on their operation on the body. The examples I have selected are from the best English, French, and German writers, and I have endeavoured to prove to you that not one of them can be regarded as unexceptionable. Our *positive* knowledge of the action of medicines is, in fact, too limited to allow us to form classifications of this kind independently of theory.

Physiological Classes, or Groups. — Certain associations or groups of medicines are by general consent admitted, though it is oftentimes difficult to define accurately the boundaries of each. In describing the effects of the individual articles of the materia medica, I shall, to avoid repetition, frequently employ terms which have reference to the common effect of each of these groups, or classes. Many of these terms require no explanation, as they are in common use, and their acceptation is generally agreed on; for example, emetic, purgative, &c. There are others, however, which require some explanation, since different authors are not agreed on the sense in which they are employed. I propose, therefore, in the next lecture, to offer a few explanatory remarks on these.

CASE OF

EXTRA-UTERINE PREGNANCY,

IN WHICH THE FŒTUS WAS REMOVED FROM THE ABDOMEN BY INCISION,

Fourteen Months after Conception.

To the Editor of the Medical Gazette.

Sir,

If the following case of removal of an extra uterine fœtus from the abdomen, should appear to you sufficiently interesting for insertion in your journal, you will oblige me by giving it publicity.—I am, sir,

Your obedient servant,

F. Hutchinson.

92, Farringdon-street,
Oct. 26, 1835.

Mrs. J——, æt. 28, living at 5, Butcher-hall Lane, of an active disposition and healthy constitution, has been married eleven years without having borne a child, and was always perfectly regular in regard to the catamenia until August 4, 1834, when that discharge appeared for the last time. In consequence of its suspension she considered herself pregnant, and was confirmed in that opinion as well by the declaration of the medical gentleman to whom she applied for advice, as by her own feelings. His statement was, "that she had every symptom attendant on such occasions." From the beginning of September, she states that the breasts enlarged considerably, and that a milky fluid was secreted in such quantity as to be readily squeezed out on the application of pressure; the areolæ around the nipples also were deeply shaded. Her person enlarged more rapidly than is usual in early pregnancy, so that by the middle of September she had acquired a considerable bulk. It was remarked that the abdomen was more prominent on the left side than on the right. She now became the subject of occasional spasmodic pains in the back and the region of the stomach; and so violent were these attacks as to produce syncope and deprive her of all consciousness, while they lasted. During the month of October she believed that she felt the movements of a child distinctly. Her increase in size was regularly progressive, but so quick that she was represented to have been as large by the end

of January as the generality of women are at the full period of gestation. After the month of December had passed, she felt the movements of the child continually, and it seemed to become daily stronger: the enlargement continued to be greatest on the left of the linea alba. At the end of April she was seized with periodical uterine pains, attended with much expulsive effort. She then considered herself in labour; especially since (according to her own calculation) the ninth month of her pregnancy had expired. The pains continued for nearly three weeks, accompanied with a discharge from the vagina of clear fluid, sometimes mixed with blood, and at other times assuming a yellowish appearance, amounting altogether, she believes, to about two quarts; and after the passage of two or three stringy substances, they gradually subsided. She suffered at intervals, during this period, great agony from the restlessness of the child; after which it ceased to move, and she has not felt it since. Still, however, her abdomen continued to enlarge, and her legs became œdematous. From the latter part of May she gradually wasted; her breasts and lower extremities shrunk to less than half their former dimensions; her appetite failed; and general debility ensued. The size of the abdomen, however, remained nearly stationary.

The preceding statement constitutes the history and symptoms of the case until the 14th June, 1835, when Mrs. J. first called at my house. The symptoms then present were as follows:—She was much emaciated, but her general aspect was not unhealthy. Pulse 100; tongue clean; bowels indolent, unless their action was excited by purgatives. Her sleep was sound, and appetite good, but she felt afraid of taking solid food in consequence of its producing pain in the stomach, accompanied with flatulence. She complained of pain in the lower part of the back when in the erect position, and a dreadful sense of suffocation when recumbent.

On an examination per vaginam, that canal was found to be shorter than natural, and its sides were compressed by the protrusion of a large tumor, occupying a portion of the pelvis between it and the rectum. The os uteri was indistinctly felt, conveying to the touch an impression that the fundus was turned downwards and backwards, and the mouth forced up behind the pubes.

I did not see the patient again till July 8th. I found her much altered for the worse, and considerably more reduced than when the former observations were made. The pulse was now 115; the respiration laborious; tongue dry and furred; there was a disagreeable taste in the mouth, and the bowels were constipated; there was also frequent vomiting of a white frothy fluid; pain in the back; constant desire to pass urine, which was voided in small quantities, and its evacuation afforded only temporary relief, from the painful sense of distention. She suffered frequent forcing and bearing down pains, with cramps in the legs; and her nights were disturbed and sleepless.

Dr. Ramsbotham visited her with me on July 9th, the symptoms being then as just described. After examining the tumor externally, and by the vagina, he was of opinion that the case was one of ovarian disease, and that paracentesis abdominis ought to be adopted.

Dr. F. H. Ramsbotham saw her, in company with his father, on the 12th; and from the distinct sense of fluctuation communicated to the hand on examining the abdomen, considered that there was ascites complicated with ovarian enlargement. He concurred in the propriety of letting out the fluid, and thought that as little time as possible should be lost before the operation was performed.

On the 15th, in the presence of Dr. F. H. Ramsbotham and Mr. Margetson, I introduced a large-sized trochar through the abdominal parietes, in the linea alba, about two inches above the umbilicus, where the tumor was most prominent. About six pints of a thick, sizy, chocolate-coloured fluid escaped, possessing an unpleasant, though not highly-fœtid, odour. This proceeding afforded considerable and almost instantaneous relief to the suffocating sensations the patient had previously experienced. On the discharge of the fluid Dr. F. H. Ramsbotham expressed surprise at its character, having been previously impressed with the conviction that it was contained in the peritoneal cavity. The aperture did not heal, and a fluid continued to be discharged daily, which at first resembled that let out by the trochar, but became by de-

grees more offensively fœtid, until a fortnight after the operation, when a small lock of fœtal hair was observed in it. From this date pieces of the same kind of hair passed repeatedly, as well as globules of oil and portions of putrid skin, with some membrane, which was described by the patient as resembling fœtal intestines, and which could be drawn out by the fingers to a considerable length. A hard circumscribed substance could now be distinctly felt through the abdominal parietes, in the left hypochondrium, evidently the head of a child, and no doubt remained in the mind of either Dr. F. H. Ramsbotham or myself as to the true nature of the case. She remained much in the same state throughout August; but before the middle of September all the symptoms became aggravated. She suffered much from constitutional irritation; the pulse rose to 120; there was great thirst, and her appetite was impaired, which she attributed to the offensive effluvia that arose from the putrid discharge.

On September the 21st Dr. F. H. Ramsbotham again met me, and I proposed making an incision sufficiently large to remove the child. To this measure he objected, thinking putrefaction had gone on to such an extent that the body could not be extracted entire, and that the frequent introduction of the hand would be required for the purpose of emptying the cyst in which it lay; but he thought it would be desirable to enlarge the aperture to the extent of an inch or two, that the fluid might have a more ready exit, and that an opportunity might be afforded us of examining more accurately the degree of decomposition that had taken place.

Accordingly, on the next day, in the presence of that gentleman and Mr. Margetson, by means of a director and bistoury, I made an incision about two inches in length downwards, below, and rather to the right of the umbilicus. A small artery was divided, the hæmorrhage from which, however, was easily checked by gentle pressure; a considerable quantity of fœtid matter escaped. The finger could be introduced to its whole extent into the cyst, upwards, downwards, and laterally; and it was ascertained that the fœtal body still retained much greater firmness and solidity than had been anticipated. We were yet not perfectly agreed as to the propriety of extending the opening, and it was determined to seek the advice of a consulting surgeon. On the day after, therefore, (Sept. 23d), we obtained the opinion of Mr. Mayo; and as he concurred with me, Dr. F. Ramsbotham withdrew his objection, and it was agreed that the body of the child should be removed without delay. Besides the gentlemen just named, Mr. Margetson was present, and his opinion was also favourable for the operation.

The grounds upon which we resolved to remove the dead fœtus were the following:—

1st. The body had so much consistence and firmness, that we conjectured it would probably be *several months* before it would be sufficiently softened to come away piecemeal in the discharge; but the state of the mother's health was such, that we could not expect her to hold out *many weeks* longer unrelieved.

2dly. The original risk arising from opening the cavity of a peritoneal ovum was already got over, as far as the irritation of puncturing and admitting air into such a cavity could be prejudicial; the effect had been tried, and had not injured this patient. A freer opening might get rid of the existing source of irritation in the abdomen, but did not seem likely to add another.

3dly. It was evident, from examination by the finger, that the cyst enclosing the fœtus lay before the bowels, and behind the abdominal parietes; and that the existing wound might be enlarged upwards and downwards in the direction of the linea alba, without endangering the opening of the free peritoneal cavity, or dividing any part of the reflected peritoneum, which was not adherent to the outer membranes of the ovum.

The operation was performed in the following manner:—

I enlarged the aperture, both above and below, to the extent of about five inches. Mr. Mayo then introduced his hand, and grasped the left upper extremity, which he brought out of the wound; but the transverse position of the fœtus prevented its being extracted by that member; the arm was therefore separated at the shoulder. The part that was next taken hold of was a foot; this was then drawn out, and the trunk afterwards extracted without difficulty; the head, however, was too bulky to come away entire, and on the suggestion of Dr. F. H. Ramsbotham.

the cranium was punctured with a scalpel in the lambdoidal suture; a quantity of offensive gas instantly escaped; the bones collapsed and passed readily.

The removal of the child was followed by a flow of the same kind of offensive, brown, putrid fluid, which we had before remarked. The funis was divided; a portion of it, with some membrane, was left hanging out of the wound. Upon gently pulling the maternal end of the funis, the placenta was felt to be still adherent: no attempt was therefore made to remove it. The wound was dressed with a strip or two of adhesive plaister, and poulticed, an opening being left at the lower part to allow the escape of the fluid still within the cyst.

The operation did not occupy much more than five minutes, and was borne by the patient with the greatest fortitude. No vessel was divided that required to be secured; but a slight faintness came on soon after its completion. The fœtus was as large as an ordinary one at full time, and the cuticle was perfect except on the scalp, whence it had entirely separated, and over the vertebræ and the joints of the fingers and toes, which were denuded.

Sept. 24th.—Met Mr. Mayo and Dr. F. H. Ramsbotham, the latter of whom has continued to attend with me three or four times a week from this period. She has passed a good night; expresses herself much relieved; the countenance is cheerful; pulse 115, but evidently excited by seeing us. There has been no rigor or sickness; no pain or tension on any part of the abdomen. The bladder has acted two or three times; one motion of a natural appearance has passed: a larger portion of membranes than was apparent yesterday is hanging out at the lower part of the wound: she complains of being hungry: the dressings were not disturbed. It was not thought necessary to administer any medicine; but she was allowed a little broth.

25th.—Another comfortable night; we found her eating some flounders. Pulse 100, no pain, and the bowels and bladder had acted. The fluid discharge since yesterday has been trifling; but a considerable part of the placenta is offering itself at the aperture. The whole of this organ was drawn away most easily by a pair of forceps; it was perfectly putrid: the cellular web having been entirely destroyed, and the vessels separated from each other, hung down like strings. It had the appearance, indeed, of having been a long time macerated in water. It was smaller than a uterine placenta. About a pint of fœtid fluid followed its extraction. Dressed as before.

From this time she continued improving, the discharge varying daily from about four to eight ounces, but still very fœtid in character. Not a single bad symptom appeared until Oct. 2, when she complained of slight gastric uneasiness, which she attributed to having eaten some turnips. To relieve this, a mild dose of the compound decoction of aloes was administered; it produced, however, so much relaxation, that it was thought necessary to order an astringent. The purging was soon checked, and she became again free from uneasiness. The wound is now very much contracted, and the edges granulating: she has sat up two or three times. She continued again to improve till the 8th, when she was attacked with constant pain on the right side of the abdomen, extending from the ribs to the spine of the ilium, and the least pressure caused an aggravation; there was also sympathetic fever. The discharge from the wound has become changed, both in colour and smell: it is yellowish, as though bile was mixed with it, and possesses a slight fœcal odour. Pressure on the right side of the abdomen produces an increase of discharge, and an evacuation of gas: the bowels continue to act naturally; the size of the aperture is much diminished. Fomentations relieved the pain, and saline medicines seemed to allay the fever. From this date, the 8th October, the general symptoms have remained much the same, although upon the whole the aspect of the countenance has improved; the discharge has been occasionally feculent. Upon our visit yesterday we found her in good spirits: pulse 98, rather small. She sleeps well; her appetite much improved. The bowels have acted daily once or twice. At the bottom, and on the edges of the wound, healthy granulations have sprung up, which have contracted the opening to the size of about half an inch. The discharge consists almost entirely of pus from the granulating surface, and that in moderate quantity. The flaccidity of the abdominal parietes, consequent

on the extraction of the child, has, Oct. 26, entirely disappeared; she has been able to sit up, dressed, for two or three hours every day, since Thursday last, without fatigue; can walk without pain, and she seems in a fair way to be eventually restored to health.

SOME OBSERVATIONS ON ANIMAL TEMPERATURE AND VITALITY,

Suggested by Dr. Williams's Letter in the last number of the Medical Gazette.

By A. P. W. Philip, M.D.

To the Editor of the Medical Gazette.

Sir,

I am sorry to see that Dr. Williams declines the proposal I made, because, till the functions of the sensorial and nervous powers are clearly distinguished, and the nature of the latter ascertained, all discussions respecting them must more or less be, as they have always hitherto been, involved in error and consequent confusion; a striking instance of which I am now to consider.

He will find, I think, on a more careful review of the subject, that his opinion of the cause of animal temperature is much too confined; and that there can be no greater error than that the spinal marrow does not contribute to its maintenance, the contrary of which is proved by direct facts. The confusion which prevails on the subject cannot, I think, be better illustrated than by the circumstance of a person so well acquainted with it as Dr. Williams supposing that animal temperature can in any degree be maintained by the functions of circulation and respiration after the influence of the nervous system is wholly withdrawn*.

It has been found by experiment, that in proportion as the function of the spinal marrow is impaired by destroying part of this organ, the temperature sinks, the sinking of the temperature being proportioned to the extent of the part destroyed (my Inquiry into the Laws of the Vital Functions, part ii. chap. vii. sect. 2, 3d edition.) The maintenance of animal temperature depending on functions which take place in every part of the system, and these, being, like the other assimilating processes, functions of the central parts of the nervous system, can only be generally influenced by causes which influence the functions of these parts, not by causes which prevent their influence from reaching particular parts of the body. Thus the stomach may have its nervous influence so impaired by so dividing and separating the divided ends of the eighth pair of nerves, as to destroy its functions, with little if any sensible decrease in the general temperature of the animal, because the whole power of the brain and spinal marrow remains, although the full influence of the former is prevented reaching that organ. But when the same effect on it was produced by destroying the lower half of the spinal marrow, the actual power of the brain and spinal marrow being thus reduced, there was, along with the loss of power in the stomach, such a diminution of the temperature, that in a few hours after the operation the animal shivered violently, which could only be prevented by keeping it in a very high temperature, which, indeed, seemed necessary to prevent its dying of cold, because here the general source of nervous influence was impaired.

The temperature was for a similar reason much impaired in Mr. Brodie's experiments, by which the general powers of the nervous system were enfeebled—that is, of the brain and spinal marrow—the only active parts of that system *. From mistaken views of the functions of the spinal marrow, succeeding writers have, in speaking of the effects observed in Mr. Brodie's experiments, not taken into account the effects they necessarily produced on this organ, as well as on the brain.

The functions of the spinal marrow are as essential to the maintenance of animal temperature, and indeed of all the assimilating functions, as those of the brain itself. Nor in these, as in the sensitive functions, does the brain act through the spinal marrow, in consequence of which, in the more perfect animals, the sensitive functions of the spinal marrow cease on the removal of the brain. The vital functions of the former organ, on the contrary, remain, and are not immediately impaired by

* Med. Gaz. October 10th, p. 50.

* See a paper in the Philosophical Transactions for 1833, republished in my treatise on Sleep and Death.

the removal of the brain. Hence it is that the temperature is, to a certain degree, maintained by artificial respiration after its removal.

When the nervous influence is wholly lost, the mechanical parts alone of circulation remain. It is impossible, under such circumstances, that any degree of animal temperature can be maintained, the chemical part of the vital functions wholly depending on that influence.

In the last sentence of Dr. Williams's last communication, an opinion is expressed, tending (as far as I am capable of judging) to divert the attention from the only principle on which correct physiological views can rest.

"Whilst," he observes, "we admit the possibility of electricity having properties yet unknewn, which may hereafter explain the various processes of organic life, we must for the present content ourselves with referring them to a cause, of which we confess our ignorance by calling it vitality."

What is meant by saying that we must confess our ignorance of vitality? If the nature of vitality be meant, the expression is correct. But is not the same true of the nature of all other principles of action? Take any of the most familiar instances. Do we know more of the nature of gravitation than of vitality? What do we mean by a knowledge of any such principle but a knowledge of its properties?

The apparent greater mystery of vitality arises, not from its being more mysterious than any other principle of action, the nature of all is equally so, but from the properties of vitality being more varied, less easily made the subject of inquiry, and bearing less analogy to the phenomena most frequently presented to us.

Both the chemical and mechanical powers of living animals are under the influence of their vitality, on the same principle as the electricity of the magnet is under the influence of magnetism; and we are no more in the one instance than in the other precluded from ascertaining by observation and experiment in what respects and to what extent the modification takes place.

Let us adopt a more correct language. Let us cease to talk of the obscurity of the vital principle,—it is no more obscure than all other principles,—but speak of the difficulties of ascertaining its properties; for the properties alone are all that we know of any principle of action,—difficulties which here depend on the variety of the phenomena, the complicated and varying nature of the subjects of our observation and experiments, and the little analogy which exists between the properties of vitality and those of other principles of action, which renders the former less familiar subjects of contemplation; for the striking analogy which exists among the phenomena of all the principles which operate in inanimate nature is greatly modified in many of the phenomena of the living animal, and wholly lost in those in which no inanimate agent interferes.

We thus speak a language which can at once be understood. To talk of the obscurity of the vital principle, implies that we know more of the nature of any other principle of action.

It is in no instance the nature, but the properties alone of any principle that can be ascertained by observation and experiment. They alone are the objects of our senses. A knowledge of the former is equally in all instances not merely beyond the limits, but the nature of our minds. The blind may as well attempt a knowledge of colours. And it will surely be admitted that the properties of the vital principle may be made the subject of observation and experiment as well, though not so easily, as those of any other principle of action. The greater difficulty, which arises from no other cause than the properties of vitality being both a more complicated and less familiar subject, lessens as we proceed, provided we steadily reject the influences of prepossession and imagination, so ready to intrude where the facts are at all complicated or obscure.

Nothing shows in a more striking manner the inaccuracy of our reasonings respecting the phenomena of life, than that writers who deservedly stand high, even Hunter, and others of hardly less name, have confounded together the vital principle and nervous influence, a mistake not less, and, as far as the nervous influence is modified by the vital principle, precisely of the same kind as if they had confounded the vital principle with muscular contractility, one of the properties bestowed by that principle with the principle itself.

In the living nervous and muscular systems, and the living blood, reside the

properties of the vital principle. The properties peculiar to them, therefore, we must study, if we wish to become acquainted with that principle, in the only way in which we can become acquainted with any principle of action; and is this study, although certainly beset with greater difficulties, at all more hopeless than the study of the properties of electricity or gravitation?

Let us, then, cease to talk of the hopelessness of a knowledge of vitality, a position originally the mere result of that indolence of mind which shrinks from difficulties, and maintained by the power of habit, and the circumstance of not giving ourselves time duly to consider the question.

We have precisely the same means of acquiring a knowledge of vitality as of all other principles of action.

Its properties are as open to observation and experiment as those of any other principle, and we know nothing of any principle but what is acquired by these means.

I abstain from farther observing on the subjects on which Dr. Williams touches, convinced that, till we are agreed respecting the question stated in my last communication, any more particular discussion of them would be little better than loss of time.—I am, sir,

Your obedient servant,

A. P. W. PHILIP.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

On Bloodletting. An Account of the Curative Effects of the Abstraction of Blood; with Rules for employing both Local and General Blood-letting in the Treatment of Diseases. By JAMES WARDROP, M.D., Surgeon to the late King, &c. &c.

JAMES WARDROP, *M.D.*! Mr. Wardrop, who has all his life affected to despise physicians, now striving to add something to his respectability by engrafting his new claim to the doctorate on his old standing title of "Surgeon *to the late* King,"—a piece of Heidelberg lace upon a thread-bare court dress! Doubtless the worthy *Doctor* has seen the error of his ways, and now only desires that the public should learn to regard him as occupying a place among the *other* metropolitan physicians of the day.

The volume before us consists of seven short lectures, now called "discourses," which the author informs us have already been published *elsewhere*; but with a prudential reserve worthy of all praise, omitting to state the work in which they appeared, and avoiding the name of the *Lancet* by a process as circuitous as the circumlocution of the traveller who informed his readers that on a particular day he crossed a river, "the name of which (he adds), for brevity's sake, I shall here omit to mention." As to the *Doctor*, having passed the Rubicon when he became one of the contributors to the Lancet, he should have made up his mind to brazen it out boldly; for he may rest assured that *where* his "discourses" appeared can no more be consigned to oblivion by such omission, than the author of certain "intercepted letters" can be concealed by their being published without a signature.

The circumstance of the discourses having originally consisted of lectures gives to them an elementary character, and has led to the statement of many truisms, or, at least, of facts so familiar as to render it matter of some surprise that their formal enunciation should have been deemed necessary. Thus we are informed that "the blood which is contained in the heart, in the arteries, and in the veins, is kept in a continual motion, called its circulation;" that "when serum collects in a preternatural quantity, either in the cellular texture, or in any of the serous cavities, as those of the pleura, pericardium, or peritoneum, it produces a disease called *dropsy*," &c. &c. There are numberless other paragraphs of the same nature, so very true, and so very well known, that the author might safely have omitted them. Again, we meet with some passages between the clauses of which there is no connexion whatever; or none that we have ingenuity enough to discover. Thus, we are told "Dr. Tweedie once saw the buffy coat in blood taken from the temporal artery of a person labouring under pneumonia; and the great prevalence of the buffy coat in diabetes, first lead [led] Dr. Watt, of Glasgow, to treat that disease by frequent bleed-

ings." Now we are utterly at a loss to discover what connexion exists between Dr. Tweedie having seen the buffy coat form upon arterial blood once — or one hundred times — and Dr. Watt adopting the plan of bleeding in diabetes. It is a complete *non sequitur*. Dr. Watt was led to bleed in diabetes, not because Dr. Tweedie, or any other person, *once* saw the buffy coat in *arterial* blood in pneumonia, but because he himself very often saw it in *venous* blood taken from diabetic patients. Neither is the phenomenon of buff occasionally forming on arterial blood confined to the testimony of Dr. Tweedie, having been witnessed by the late Dr. Gordon, of Edinburgh, by M. Gendrin, and others.

The same ignorance of well-known facts is shewn in other points. Thus, in the very next sentence, the authority of Dr. Hamilton, of Edinburgh, is quoted to shew that the buffy coat is sometimes seen on the blood of persons who are under the influence of mercury. Could Mr. Wardrop not have stated this on his own authority?—or is he ignorant that in scurvy and various other cachectic conditions, the same phenomenon is occasionally witnessed?

But what, after all, does this book pretend to teach? What in the shape of original information is there given in it? We can hardly believe that it requires the revelation of a newly-dubbed *Dr.* to tell us that "he who is in the habit of prescribing the abstraction of particular quantities of blood, in like manner as he may be accustomed to write the prescription for a dose of medicine, must possess a very incompetent knowledge of all the advantages which are to be derived from the judicious employment of this most useful, and no less powerful, remedy."—Page 148. Nor, surely, does it need Dr. Wardrop's authority to inform us that "the state of fainting is an unerring criterion for estimating the extent to which blood should be removed in those cases where general bleeding is most expedient—such as inflammatory diseases attended with febrile disturbance, and in congestions affecting the vital organs."—P. 72.

Does Mr. Wardrop really flatter himself that the world is now, for the first time, informed of these matters; and that to him we are indebted for these novel hints regarding this "useful and no less powerful remedy?" If he does, we are amazed at his simplicity. We believe the credit of having first put forward, in a strong light, the practical utility of attending to these points, is eminently due to Dr. Marshall Hall; whose work on Blood-letting* we are surprised that Mr. Wardrop does not once mention from the beginning to the end of his little volume. We may take this opportunity of recommending Dr. Hall's valuable work to our readers; they will find in it also several other rules and observations of great importance, relative to blood-letting as a diagnostic of diseases.

In fact, the practical portion of the publication before us may be stated in a single sentence: — bleed, when your patient has an incompressible pulse, whatever be the name of the disease; and bleed till you subdue the pulse, whatever quantity may be necessary for this purpose. This, we think, is a fair representation of Dr. Wardrop's doctrine; and it is in the main a good one, though the manner in which it is illustrated and enforced shews great ignorance of what has often been said on the same subject by others. Thus, several pages are occupied in arguing that bleeding may be employed in the eruptive fevers, where the same symptoms are present as would indicate it in any other disease; as, for instance, it is said that in scarlatina, when the inflammation of the throat is "severe," relief is afforded by local bleeding; "but when any of the vital organs are affected, then venesection is preferable." Is there any man who has been a year in practice—any tyro who has passed his examination at Blackfriars—who imagines that in inflammation of a vital organ he is to refrain from venesection if his patient happen to have scarlatina or measles? We maintain that there is no novelty whatever in the general principle which Mr. —we beg his pardon—*Dr.* Wardrop labours to establish, just as if it were a great doctrine in physic peculiar to himself. It is true that by repeating the same thing many times, and by instancing many different diseases (though in a very superficial manner) he endeavours to convey the idea of his having had to

* Researches principally relative to the Morbid and Curative Effects of Loss of Blood; by Marshall Hall, M.D. F.R.S. London, 1830.

overcome numerous erroneous opinions which he assumes to exist. Still, when we strip what he says of its disguise, it always comes to this—that where there is violent general reaction, blood may safely and advantageously be abstracted till an impression be made upon the pulse; in which recommendation we humbly submit that, however true it may be, it possesses no novelty whatever.

In some few instances, instead of adhering to the safe general rule above mentioned, our author ventures upon an exclusive and unqualified injunction; thus we are informed, that "*whenever* the abstraction of blood is necessary in the treatment of erysipelas, general is to be preferred to local blood-letting." A more unfortunate selection for such an exclusive recommendation could not well have been made; and this is the more remarkable as the disease is surgical, and therefore one with which Mr. Wardrop might be expected to be familiar. We say, with all deference to our author, that there is no inflammation of equal severity in which local is so frequently preferable to general bleeding; particularly in the form of scarifications. Neither is it correct, as implied, that, in our public hospitals, erysipelas is treated by "as much bark as the stomach can receive." Mr. Wardrop here, as elsewhere, either is ignorant or affects ignorance of the actual state of medical practice. If he will take the trouble to visit the public hospitals (which, from his writing, we suspect he never does) he will find, that though some of the older practitioners still retain the idea of specific influence being possessed by cinchona over erysipelas, yet that the great majority treat the disease on general antiphlogistic principles; but he will also find that there is no form of inflammation which is so frequently attended by depression, and by so much tendency to sinking, or which so often requires the use of stimulants and tonics; particularly bark.

There is one position of the author's which we are quite certain is replete with *danger*. Mr. Wardrop observes, page 125,—"In the treatment of all *inflammations*" "the blood should be abstracted from the arm whilst the patient is in the recumbent position, until syncope be produced." However safe it may be to bleed to incipient syncope in the *erect* position, we are quite satisfied, from much experience, that blood-letting carried to syncope in the recumbent position is a measure at once unsafe and unnecessary. Nay, we would venture to assert, that it is quite as wrong to bleed in the *recumbent* position, in *any* case, as to *prescribe* the quantity of blood which may be withdrawn.

That we have been disappointed in the volume before us, must ere now have become evident to our readers; and we confess it does surprise us, that any thing which Mr. Wardrop has been "employed in collecting and revising many years," should be so superficial, or should have been given to the public in so crude a form. The only praiseworthy part of the volume is the "getting up" by the publisher—which is exceedingly good.

Medico-Chirurgical Transactions. Published by the Royal Medical and Chirurgical Society of London. Vol. XIX.

The principal feature of novelty in the present volume is that it appears as containing the Transactions of the *Royal* Medical and Chirurgical Society. A copy of the charter serves as a preface, and the papers which follow are numerous and important; but as we have already, at the time of their being read, given full and accurate reports of them, we do not find any thing to add or to correct. Dr. Robert Lee continues one of the most indefatigable contributors, having furnished not less than three papers. There is also an exceedingly elaborate essay on various affections of the brain, by Dr. Sims.

Although we thus express a very favourable opinion of the volume, we would nevertheless strongly urge the necessity of the cases being condensed in future volumes—many of those before us being detailed with the most tedious and unnecessary minuteness. The Council ought to look to this. That numerous cases have been read in detail, is no sufficient reason for their being published, except with the most rigid curtailment that is consistent with perspicuity; and even then we think that mere cases to illustrate the opinions adduced in a paper ought to be printed in a smaller type, without separation into paragraphs, with wide interstices—as in many of those before us.

MEDICAL GAZETTE.

Saturday, November 7, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

MEDICAL ATTENDANCE ON THE COUNTRY POOR.

In our last number we had occasion to point out some instances in which the medical police (if it may be so called) of this country is lamentably mismanaged. Had we room at the time to insert Mr. Rumsey's circular (see page 190), we should have felt called upon to add some further remarks on the same subject. Since then our attention has been called to an able and well-written letter in the *Times*, which so clearly sets forth the inefficiency and paltry meanness of the system at present pursued by the Boards of Guardians throughout the country, under the auspices of the new Poor Law Commission, that we cannot refrain from bringing certain passages of it more immediately to the notice of our readers.

We pass over (inasmuch as we have ourselves treated the subject largely before) the writer's observations on the preposterously unequal duties imposed on the practitioners employed under the new system. Every body has heard of the superabundant pauper populations committed to the charge of the new comers; it is, however, of some importance that the facts should be vouched for by an authority so candid as Ruricola evidently is. Pass we on, therefore, to his remarks on the method of portioning out the sick poor into districts:—

"Again, the unions are divided into districts, and no doubt wisely so, for *relieving* officers, or for general purposes: but though these districts bear not the remotest regard to the practicability of medical attendance, yet are they peremptorily forced upon parochial surgeons, and their pauper patients, to the great injury of both.

To insist upon identity between districts for general relief, and districts for medical relief, is manifestly absurd. The fanciful divisions made by these new authorities cannot, in a rural population, suddenly alter conventional arrangements, the growth at least of a generation, and often of a century. Each village and parish in the country has long ago decided in what directions it is most suitable to send for medical advice; and the comfort and advantage of all parties depend upon the medical districts of the unions being founded upon these results of experience: any arbitrary attempt to force different distributions of this relief upon the country can only end in disappointment and additional expense, because the total amount of the labour of medical men within the district must be increased by it, and so ultimately must the cost of that labour be enhanced."

The consequence of this is, that the medical officer, be he of what *physique* he may, being utterly unable to fulfil his engagements single-handed, is obliged to procure assistants; and to these is eventually intrusted the irresponsible care of the unfortunate sick poor.

Let us take another example of the working of the system—by which we shall be enabled still further to judge of its fruits.

"The next point to which I beg to invite attention is the mode of giving orders for medical relief. This is in almost every case left to the relieving officer of the district; for although the 54th section of the Poor Law Amendment Act permits the magistrate to direct medical relief in urgent cases, yet this permission is, in fact, merely nominal. I have not yet heard of an instance of its being made use of. The relieving officers, having the power, are generally allowed to exercise it exclusively. Now, if these functionaries would confine their judgment in cases of sickness to the question of how far the patient's circumstances entitle him to parochial assistance, it might do well enough; but they usually think themselves competent also to decide *how far the pa-*

tient's illness may require medical attendance. I need not point out the hardship that such a discretionary power must inflict on the poor; indeed, I could bring forward numerous instances of the sick paupers having lingered for the want of medical aid—because, forsooth, the relieving officers thought their cases too trifling for attention * * * * Another hardship inflicted on the poor is the distance to which they are obliged frequently to send, in agricultural districts, both for orders from the relieving officer, and for attendance from the surgeon. In many of the new unions the medical officer resides more than ten miles from the patient. Now, those who are acquainted with the habits of the poor know well the difficulty they experience in merely sending for a medical attendant. Even if they can procure a messenger, a day's work must be lost by a journey to such a distance; and there is, of course, great uncertainty in meeting with a surgeon who is obliged to be almost constantly travelling about an extensive district. It is, therefore, not surprising that the length of time before assistance, either by a visit or by medicines, can be afforded, is often attended with most serious consequences."

It must be recollected, too, that the relieving officer is a man of many avocations,—that he has generally five or six parishes to attend to, and the distance of his residence may be as great as that of the medical officer's—perhaps, also, in an opposite direction. Can greater cruelty be devised than that which must in many instances ensue in consequence of these arrangements?

The arguments of Ruricola in favour of the local practitioners, and proving the inefficiency as well as the vexatiousness of introducing a new set,—a race of adventurers among them,—are strong, and well worthy of consideration; and we are particularly pleased with the light in which he places the "tender" system. But our limits will not allow us to make many more extracts; nor, perhaps, is it very necessary that we should, especially on this subject, as we have already on other occasions so fully expressed our own sentiments upon it.

Another grievance touched on by this well-informed writer is the mode of payment adopted by the so-called Guardians of the poor,—paying the practitioner a miserable pittance per case. The usual rate is 2*s.* 6*d.*—*half-a-crown* for attending a patient *through an illness* long or short, providing medicines, and travelling perhaps twenty miles on each visit! There is a slight increase in the fee, it seems, when the number of cases is inconsiderable during the year; but in no instance, says the writer, does it exceed *four shillings*.

"For this trifling sum the medical officer is to attend the most important illness. Fracture of the skull—or typhus fever, requiring visits daily, or twice and thrice a day, at the remotest point of one of these immense districts, with a due supply of apparatus, leeches, medicines, &c. is to be attended for any length of time, short of 12 months, for 2s. 6d. Perhaps such a preposterous payment will be defended in this way—'the slight cases are much more numerous, and the average will produce a very fair salary.' Supposing, for the sake of argument, that if all the slight cases were sent to the medical officer, a fair salary would result (which, however, I am prepared to disprove), what will be thought of it when the relieving officer is instructed not to give orders for relief in trifling cases, and is allowed to decide which are and which are not trifling,—a decision that might perplex the profoundest physician? The injustice is yet further increased, when in addition to this the time during which a sick pauper may linger for want of an order may convert any trifling ailment into a serious and fatal disorder. And although in a dense population containing many pauper patients within a limited extent a small sum like 3s. or 4s. on all cases, without reservation, might produce something like a fair salary, yet it is manifest that this must be absurdly insufficient for a small number of patients residing at a great distance from the medical officer, or dispersed over a great extent of country. Nevertheless,

on no account will the commissioners allow of any increase of charge according to the increased distance of the patients, whether the salary be by a payment per case, or by a fixed sum. Here, however, is not the end of these oppressive terms, for lest by any possibility (the occurrence of an epidemic, &c. for instance) an unusual number of paupers should fall ill, the cases for which this payment is to be made are limited to a certain number, all beyond which the medical man must attend gratuitously!"

Yet there are those in the profession who accept these terms, and thus countenance the commissioners in their insulting conduct! We cannot otherwise denominate that conduct—that mode of dealing with medical men, which has so much that is degrading and disgraceful connected with it. Threats have been unscrupulously thrown out to induce the resident practitioners to accede to the terms proposed; their motives have been aspersed, and attempts have been made to bias the public opinion against them. With all this, we say, persons have been found mean enough to submit to the degradation offered to them and their order! Is there no unanimity, no consistency, no *esprit de corps*, remaining among even the humblest members of the profession? Has the scanty allowance tendered by the *patronizing* hand of heartless overseers such temptation in it, as to subdue the manly and generous feeling of those professing to belong to a liberal vocation? But we cannot persuade ourselves to acquiesce in such an opinion. We are rather disposed to believe that the parties to whom we allude are tempted to pursue their present course, trusting to the impunity of obscurity. They hope to escape exposure (they must have had a stock of bad principles to begin with), and they are reckless of all that can operate on a well-conditioned mind.

They will fail, however, in this object, we hope and we trust: the truth must come forth. We have great expectations of the result of the circular issued by the Association, of which Mr. Rumsey, of Chesham, is the secretary; and we are convinced that, ere long, we shall be possessed of a mass of facts which must have great influence with the public mind. As it is, we can scarcely believe it possible that the government is duly apprized of the real state of things. The public at large cannot be aware of it; otherwise the illiberal and narrow-minded functionaries, the ungenerous hirelings, who bring disgrace upon the institutions of the country by the scandalous way in which they exercise the discretionary power committed to them, would sink beneath the weight of general indignation. It is provoking to witness the operation of a system like this, which adds insult to inefficiency, while it is profusely payed for out of the public purse.

EXTRAORDINARY SCENE AT ST. BARTHOLOMEW'S.

An account will be found at page 189, of a *scene* which took place at St. Bartholomew's last Saturday, and which we can scarcely suffer to pass without comment. There has hitherto been an understanding among the officers of the metropolitan hospitals, that the pupils at each of these establishments should be admitted to the others when any important operation, or similar opportunity of acquiring professional information, presented itself; but this accommodation has always been afforded as an act of courtesy and favour, and of course under such restriction as to prevent it from interfering with the prior claims of the regular pupils of the hospital. In this way many gentlemen entering to one of the London hospitals

have had opportunities of witnessing operations by nearly all the eminent metropolitan surgeons of their time; and there can be no doubt but that great advantage has thence accrued to the profession. To expect, however, that the pupils of any school should be be allowed to pre-occupy the benches of the operating theatre in another, whilst the proper pupils of the hospital are absent at lecture, is evidently quite unreasonable. It is very natural that gentlemen should be desirous to see as much practice, and to obtain as much information as they can—and it is doubly natural that those who at their own hospital want the requisite opportunities, should endeavour to make up for the deficiency by seeking them elsewhere—but a moment's reflection must convince them that this can only be done fairly when it does not interfere with the rights and privileges of others.

We have no doubt that the subject requires only to be noticed in order to prevent the repetition of such a scene, and to spare the necessity of enforcing that rigid system of exclusion to which it must otherwise unavoidably lead.

DEATH OF DR. JAMES HAMILTON, OF EDINBURGH.

THIS distinguished veteran died at his house in Edinburgh on the 27th ult., in the 87th year of his age. Dr. Hamilton formed a connecting link between the past and present race of physicians; and with him the last remains of the old school have completely passed away. Many of our readers, doubtless, remember him: who that has ever visited the Royal Infirmary of Edinburgh can ever forget him? Summer and winter, fair day and foul, was Dr. Hamilton to be seen stepping along, with his thin-soled shoes ornamented with large buckles, his black silk stockings, and those short inexpressible articles which cover the "nether bulk;" his formal, square-cut coat, and his redoubtable cocked hat—the whole in exquisite keeping with his upright elastic gait, and his expression of mingled shrewdness and eccentricity. He was the *beau ideal* of a physician of the last century, and with him the age of cocked hats, shoe-buckles, shorts and all, is clean gone by.

But Dr. Hamilton, though these be the points which attached him to the fancy, had stronger claims to our respectful notice; for to him we owe one of the most important improvements in the practice of modern times—a practice now universally adopted in this country; we mean that of administering purgative medicines in fever and many other diseases, in which, anterior to his time, the existence of debility was thought to prohibit their use. It is about thirty-five years since his work first appeared, and for nearly twenty years before, Dr. Hamilton had been in the habit of inculcating and illustrating his doctrines in the Royal Infirmary, which at that time was attended by students from all parts of the world, and by whom his doctrines were rapidly carried into every quarter of the globe.

Benjamin Bell, at that time enjoying the first practice in Edinburgh, married a sister of Dr. Hamilton, to which connexion the latter was much indebted for his early introduction into practice. He was appointed physician to the Infirmary when a very young man, and practised in Edinburgh for above sixty years. He is supposed to have left a large fortune, which goes to his family by a marriage privately contracted, and which was declared but a few years ago.

OFFICE OF APOTHECARY TO ST. BARTHOLOMEW'S HOSPITAL.

(From a Correspondent.)

THE apothecary of St. Bartholomew's, some time ago, determined to resign:

a circumstance of which a favoured individual was informed, and who made such good use of the information that he canvassed the Governors, addressing to them a circular printed a considerable time before the vacancy was declared. The result was, that on the resignation being made known, all those who might otherwise have come forward were deterred by finding the field completely pre-occupied.

We have good reason to believe that we have stated the facts simply as they occurred; and we may add, that from none of the said Governors did the candidate (for a vacancy which did not then exist) receive any check or remonstrance, but, in fact, that all, or a large majority, promised him their votes. Now all this is very discreditable to the hospital, and calculated to be to it of very serious injury. We trust, for the honour of the profession, that the medical officers are not implicated in the transaction; but we do think that they are imperatively called upon to free themselves from a suspicion of having connived at what is in every sense of the word a job.

The medical officers are not governors, and cannot, therefore, have a direct part in the novel kind of election about to take place;—we mean that they cannot vote. But that is not enough; the profession will expect to learn that they were not concerned, directly nor indirectly, with the tradesmen who govern St. Bartholomew's Hospital, in the perpetration of a job, and in getting up the mockery of an election without a choice.

There are some other points connected with this subject which would require more space to discuss than we can at present give to them. Here is a large hospital, with an income of 40,000*l.* per annum, in the management of which, and its vast funds, any tradesman may purchase a share for 50*l.*; and he who does so may become a contractor for the supply of goods, so as to put in his pocket many times the amount he has paid; and we know that this is not a supposititious case, but that some of those who have thus become governors are actually the tradesmen who supply the hospital—the consequences of which are too obvious to require that we should point them out. We shall probably return to this subject.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

General Notion of Symptoms—How they differ from mere Signs—The Relation of Symptoms to Diseases not the same in all cases—Symptoms are direct or indirect—Character of each.

Direct Symptoms respect the Sensations, Functions, and Structure of the part affected:—

1. *Symptoms which respect Sensation—Pain, its Degrees, its Qualities—Amount of Information derived from Pain as a Symptom—Sources of Deception arising from it.*

2. *Symptoms which respect Function—Amount of Information derived from them, as compared with that derived from Sensation—Amount from both taken together.*

3. *Symptoms which respect Structure—The information derived from them limited to parts within reach of the sight and the touch, until Auscultation brought the diseases of certain organs within the scrutiny of the ear.*

IN going round the hospital my mind often reverts to the time when I was a mere beginner like yourselves; and I remember how strange and puzzling to me was every thing that I saw; how I thought I never should be able to distinguish diseases, one from another, as long as I lived; and, as to treating them, I could not look forward with the hope that my conscience would ever allow me to attempt any such thing.

Above all, I was perplexed with the number and variety, and (as I humbly thought) contradictory nature of symptoms. It seemed to me, that if I could ever succeed in learning them all, it would be to no profit; for the same symptoms appeared sometimes to import one thing, and sometimes another.

There was a patient, perhaps, suffering convulsions; and the physician evidently thought the case most grave and perilous, for he employed several remedies of the most gigantic power, and succeeded in saving him. But there was another patient suffering convulsions no less severe, and to my apprehension just of the same kind, yet so far was the physician from thinking seriously of this case, or treating it severely, that he just looked at the pa-

tient and smiled, ordered some cold water to be thrown in the face whenever the convulsions returned, and said that would cure her; and, sure enough, he was right. Moreover, many died who seemed to me to have little or nothing the matter with them, and many recovered whom I did not hesitate to condemn to death at first sight.

Thus health and sickness, and life and death, seemed the most mysterious things in the world; and the symptoms which were said to indicate them were to me a long while unintelligible.

These recollections, at this day so often present to my mind, enable me to place myself in your situation. They serve the good purpose of making me feel, that just the same difficulties which are *yours* now were once my own, and of making me wish to aid you by my little experience in removing them.

Yet the very objects which have puzzled me, and are, perhaps, now puzzling you, do in fact contain infinite instruction. It is by symptoms, and by symptoms only, that we can learn the existence, and seat, and nature, of diseases in the living body, or can direct and methodize their treatment. But, first of all, symptoms themselves must be understood, before we can make the proper use of them for gaining the instruction which they are calculated to convey.

It is important for us to understand that the symptoms or signs of diseases are never to be taken in the like sense with that in which the signs of external things are often regarded. The buoy floating in the river, which marks its navigable tract; the bell which, by striking, denotes the lapse of time; the stone by the way-side, which tells us how far we have come, and how far we have yet to go; these are most important *signs*, and of indispensable service to us all, but they have no *natural* connexion with the things they are made to indicate. They are mere expedients, of conventional meaning and use. Navigable rivers, and time and space, would still exist, though there were neither buoy, nor bell, nor mile-stone, in the universe.

There is nothing that we call the symptom of a disease which does not contain within itself much more than a mere sign. Heat, pain, redness, swelling, are called the signs of inflammation; but nature does not intend by them barely to intimate that inflammation exists; they are essentially connected with the processes she is carrying on.

Thus at early dawn we point to the first glimmering in the east, and call it a *sign* of the rising sun; but it is more; it is an emanation from his beams. We look at the cloud above our heads, and say it is a *sign* of rain; but it is the gathering of the waters themselves.

Concerning symptoms I would nevertheless remark (what is very important to be borne in mind), that they stand in different relations to the diseases to which they belong. They may flow out of the disease, so as, in idea at least, to be separable from it; and they may be involved in the disease, so as to be identical with it. The difficult respiration, the cough, the sputa, the emaciation, the hectic, are the symptoms of phthisis, and are distinguishable from the disease itself. They are the signs of something beyond themselves which we do not see—viz. tubercles of the lungs.

But the symptoms which denote an intermittent fever are the same which constitute the disease. We have no idea of an intermittent apart from the rigor, the heat, and perspiration. The same may be said of other fevers, and almost all diseases not organic, in which, if you seek to separate the symptoms from the disease, you must resort to theory for the purpose, and conceive an action of a certain kind prior to the *actions* which constitute the symptoms, and productive of them.

There are symptoms, then, which, in the plain and intelligible sense, are signs and tokens of the disease which exists separately and distinctly from them; and there are symptoms which, however they may be spoken of as signs merely, are, nevertheless, all *that we know* of the disease itself. The disease is the symptoms; and the symptoms are the disease.

True: but it can hardly be conceived that they are in reality the same. Yet it is better that they should be so regarded, than that we should go beyond our knowledge in attempting to distinguish them. Better to see in fevers only a certain combination of symptoms, than to run wild about a debility of the nerves, a spasm of the extreme vessels, or a peccant matter in the blood.

Again, I would remark that it is often most difficult to draw the line between what is disease, and what is symptom; and that the same conditions may, in different cases, become now one and now the other. A dropsy, or an hæmorrhage, are sometimes primarily and essentially *the disease*. Sometimes they are secondary, and incidental to *the real disease*, and are themselves only symptoms.

How impossible, then, must it be to give any definition of a symptom which shall be *philosophically* true, and at the same time satisfy every sense in which it is practically regarded!

From the imperfection of our knowledge the whole subject of semeiology is

beset with philosophical difficulties; and no advantage will be gained by conducting our inquiry concerning it by a stricter method than its own nature will bear.

Whatever it is that bespeaks the presence of diseases, or denotes their nature or their seat, or, moreover, whatever indicates the proper method of treating them, may be equally regarded in the character of a symptom. At present I shall restrict myself to the symptoms which denote the disease, reserving those which indicate the remedy for future consideration.

There are certain popular tokens of disease which all the world is acquainted with. A man is generally known by his friends to be ill before he submits his case to a physician. They judge, and judge rightly, from his complexion, his aspect, his voice, his gait, or something unusual and unsatisfactory in his whole form and behaviour. And these circumstances, which strike every body, are not unobserved by us. All can gather from them that disease is present somewhere; but *we* can often draw from them intimations of its very nature and seat.

But how much soever physicians may learn from what constitutes the physiognomy of diseases in its largest sense (and, indeed, they may learn a great deal), their more accurate knowledge is derived from symptoms which admit of a more exact analysis. Upon such I propose principally to dwell.

Of symptoms some belong immediately to the part affected. They proceed immediately from it, and are referred immediately to it. We will call these *direct symptoms.* Others, belonging originally to the part affected, declare themselves through the medium of other parts, or through the medium of the constitution at large. We will call these *indirect symptoms.*

To begin with direct symptoms, there are those which respect the sensations of the part, in whatever way they may differ from what is natural.

Now concerning unnatural sensations as evidences of disease, to what extent they exist, or whether they exist at all, we are not competent absolutely to determine. In matters of feeling we must depend entirely upon what our patient tells us. Every man smarts with his own pain; himself, and nobody else, can say how much. We must presume, therefore, that our patient has no disposition to deceive us; and, giving him credit for the correct expression of his own feelings, we must act upon his information concerning them.

Pain and uneasiness! These are general terms. But there is more to be learnt upon the subject of morbid sensations than what these terms are calculated to convey.

There are qualities and peculiarities of pain arising from parts which are disordered, diseased, or injured, as there are qualities and peculiarities of sensations arising from parts which are healthy.

Ask the man whose leg has just been amputated, and he will tell you that he suffered one kind of pain when the knife divided the skin, and another when it cut through the muscles; and that sawing through the bone gave him still a different pain. Ask the man who has just suffered the operation of a violent purgative, and he will tell you, that after taking it he first felt oppression and nausea; that presently the nausea became fainter and fainter, until it was exchanged for real pain; twinges and griping arose, and became more and more acute, until they were relieved by an evacuation from the bowels.

Here we see various peculiarities of uneasiness arising from the same mode of irritation applied in succession to the different parts of the intestinal canal, and the different structures which go to the formation of the leg.

Pain in vital parts is different from common pain; and the pain in one vital part is different from the pain in another. In the brain it is heavy and stupifying; in the heart and lungs, and contiguous structures, it is apt to be acute, and generally much circumscribed, and confined to a spot; in the liver, the uterus, and testicles, it is oppressive and sickening.

Pain varies also in parts not vital. In skin, cellular structure, and muscle, it rouses and excites; in tendon, ligament, and bone, it rather oppresses; in nerve, it is numbing, prickling, or intolerably acute, and often runs along a string (as it were) to a considerable distance. Witness tic douloureux; witness the sciatic affection.

But, besides the qualities and peculiarities of pain belonging to several parts, and denoting *generally* their unhealthy condition, there are those which belong to the same parts under different states of disease, and are thus expressive of *the kind* of morbid action which produces them. There is what is called the throbbing pain, in which the patient, simply by attending to the part affected, may count his own pulse: this throbbing pain is characteristic of inflammation just at the point when it is passing from the adhesive to the suppurative stage. There is a pain which is called lancinating, almost the constant concomitant of cancer, and very different from the pain which would attend common inflammation in the same parts of the body.

The sense of pain is in proportion to the magnitude of the disease, only within certain limits. The extremity of the disease may abate or even abolish the sense of pain altogether. Thus, there are circumstances in which it is in vain to seek to learn the existence of pain by interrogation merely: the sense of it must be awakened by hard pressure or rough handling of the part in which the disease is thought to reside; and sometimes even these are insufficient for the purpose; the sense of pain is irrecoverably gone. Surely there is a benevolent intention conspicuous in all this. The way of death is often smoother than the path of life; and great bodily anguish (there is reason to believe) does not often enter largely into the process of dissolution.

But I do not wish to insist upon pain, its quantity, and peculiarities, as infallible criteria by which to detect what is the seat of the disease, and what its kind. It is possible to speculate too curiously upon morbid sensations; to speculate even so far as to deceive ourselves respecting them. Besides, the patient himself, by an over anxious and over constant attention to what he feels, is liable to miscalculate the kind and quantity of his own sufferings, and thus mislead you by exaggerating every little ache into an intolerable grievance. Again, the patient himself, by habitual disregard of what he feels, is liable to miscalculate in the opposite way. He either has no pain, or he owns to none, where another would complain of a great deal; and thus he misleads you by extenuating a real grievance, or entirely passing it by. Neither of these can be safely trusted for a correct interpretation of their own sensations

It is an important practical truth, well worthy of being remembered, that diagnosis is capable of being greatly aided or greatly obstructed by the *personal character* of the patient. Education, and the better habits of civilized life, render men more rationally attentive to their internal sensations, and better able to describe them; whereas over refinement engenders such excessive care and regard of the feelings, that it contrives to sophisticate and spoil them; and barbarity acts so much in spite of them, that it blunts or nearly abolishes them altogether.

Plain sensible men, who feel just what they ought to do, and tell just what they feel, are the most agreeable patients to attend. You make out their complaints easily and satisfactorily; they have noticed the first *real* deviations from healthy sensation, and can describe them intelligibly; and they obtain from you an earlier and more certain relief. But soft, delicate, nervous persons, who feel extravagantly, and still exaggerate what they feel, are very troublesome to deal with. You are not certain that they do not deceive both you and themselves; and such a perplexity is cast over their complaints, that you can neither understand them nor treat them properly. Again, the stupid, half civilized, who are often literally *insensible* to their disease until it has endured a long time, and made a considerable progress, and done formidable injury to the parts concerned, can hardly give you any help to the knowledge of their complaints by their own description of their feelings.

I have often remarked, in the victims of extreme intemperance, that they have little or no consciousness of the pains and disordered sensations proper to the diseases which they suffer. This strange want of correspondence between the symptoms of disease derived from other sources and those derived from the sensations, is a subject of very curious speculation medically, and of very melancholy interest morally; for the chief cause of the anomaly I believe to be really that to which I have alluded. There are whole classes of society in London who are never actually sober for years together. The sensations proper to health and to disease are alike unknown to them. In health, the stimulus of spirits, renewed day by day and hour by hour, gives them feelings and excitement which are unnatural; and however they may be mistaken for those of health, do in truth not at all belong to it. They are better, perhaps, and more pleasurable than any that health has to give; and they have superseded them. In disease (disease which it has itself produced), the stimulus of spirits gives them feelings and excitement which are still unnatural, and disguise or supersede the sensations which they then ought to have.

People are frequently brought into this hospital just ready to perish of complicated visceral disease, yet declaring that they never suffered ache or pain in their lives until a few weeks ago. Their liver, spleen, kidney, and heart, and blood-vessels, are all disorganized. They are breathing, perhaps, with one lung; and the cellular structure, and some cavities of the body, are distended with fluid. Here is disease which must have been the growth of years; yet true it is, as they say, that they have felt neither ache nor pain until within a few weeks. Spirits—spirits more or more recklessly taken, have sustained, and excited, and cheated them, with false strength and false feelings, till fluid has gushed out every where, and vital organs have been suddenly oppressed, and down they have sunk at once, and irretrievably.

Nevertheless, the inquiry into morbid sensations is most interesting in itself, and most proper and necessary to be pursued for pathological and practical purposes.

There are complaints of sensation, and sensation merely. People feel burning heat and pinching cold, in opposition to the indications of the thermometer, and in opposition to the perceptions of the physician, who applies his hand to the person of his patient, without being able to confirm the fact by his own feelings. People will complain of severe pain upon some external surface, which exhibits no visible mark of disease.

These complaints of sensation, and sensation merely, often occur in those whom you cannot suspect of an intention to deceive you. They are often real diseases, and being such, are generally most difficult to cure. But these complaints of sensation, and sensation merely, are those which people most frequently counterfeit when they have an interest in being believed to be ill; and they often counterfeit them successfully, owing to the extreme difficulty of detecting the deceit. Yet even here the physician would make the probability of deception less, if he were acquainted with the kind of pain which is usually felt in that part to which the patient refers it.

But, although we may learn from this order of symptoms all that they are in their own nature capable of teaching us, yet, in almost every case we meet with, we shall find a necessity of inquiring into other symptoms, if we would know the real condition of the part which falls under suspicion of disease. The majority of complaints are not such as declare themselves by *this* or by any one order of symptoms only. Diseases of *mere* sensation are very few.

Now there are other direct symptoms (symptoms immediately referable to the part affected) besides those which respect its sensations; and these are in truth more important, on account of the more certain information which they are calculated to convey. These other direct symptoms respect the functions of the part.

If the patient own to pain in a part, we suspect that part to be the seat of some morbid affection; but we are not satisfied that it is so, nor can we tell what the morbid affection is, until we have made further inquiry.

Suppose a man complains of pain in the head. It may be a mere nervous pain; it may be a sick headache; or it may be a symptom of inflammation of the brain. But we cannot tell what it is, and (what is worse) we cannot prescribe with any reasonable chance of procuring relief, until we have ascertained many more particulars concerning it.

Or if the patient own to no pain, yet, if a part has fallen under a suspicion of disease, we cannot be satisfied that it is healthy until we have made other inquiries. I have known people die of diseases of the brain, of the lungs, of the heart, who have suffered no pain whatever.

It appears, then, that whether we learn much or little, or nothing, respecting the sensations of a part, there is always a necessity for further inquiry, if we would know the nature of its complaint.

Our further inquiry is still into direct symptoms, viz. those which respect the functions of the part.

The symptoms which respect function are of much more practical value than those which respect sensation; and for this consideration especially, that the knowledge which they convey is less fallible in itself, being the result, not of what we ask and another tells us, but of what we see and note for ourselves. In obtaining it, we depend not at all upon the representations of the patient, but entirely upon our own observation and reasoning.

But, concerning the direct symptoms which respect the functions of parts, and which consist in the various deviations of those functions from their healthy state, let this especially be borne in mind, that, valuable as they are in themselves, to *us* they will be of much, or little, or no use, according as we take much, or little, or no care, to prepare and capacitate ourselves for understanding them. *Every body* cannot tell when and how the functions deviate from what is natural. A competent acquaintance with physiology must precede and prepare us for such knowledge. We must begin with what is natural and healthy, and afterwards inquire into what is unhealthy and disordered; and thus learn the latter by comparing and contrasting it with the former.

As the anatomy of healthy structure must always be the beginning and foundation of morbid anatomy, so must the physiology of healthy function be always the beginning and foundation of morbid physiology; for by this name of morbid physiology I will venture to call the knowledge of all the various ways in which the functions of the living body and its several parts are capable of being perverted and deranged.

Some interruption or derangement of their ordinary functions probably always attends disease or injury in every part and structure of the body; and such interruptions or derangements, being discovered,

are the symptoms which bring us home to the seat of complaint more surely than any other.

But there are parts in which they are not discoverable; namely, those of which the ordinary functions are unknown, as the spleen. And there are parts in which I will not say that they are not discoverable, but only that they are never discovered—namely, those whose functions are so mixed and blended with the functions of other parts, that it is impossible to determine how much belong to them and how much not, either in health or in disease. Who shall say when the pancreatic secretion is redundant or defective, or of an unhealthy quality?

But the brain and the nerves; the heart and the blood-vessels; the lungs, the liver, the stomach, and the kidneys; all give direct intimations of their diseases, by the interruptions and derangements of their ordinary functions.

The brain and nerves exhibit direct symptoms of their diseases in every manner and every degree in which sensation or voluntary motion, the senses or the intellect, are capable of being impaired or perverted. The heart and blood-vessels exhibit direct symptoms of theirs, in the strength or weakness of their pulsations, their unusual extent, their unequal succession, and the sounds accompanying them; also in many qualities and varieties of the pulse, and in the unequal course and distribution of the blood itself.

All are acquainted with the direct symptoms which impute diseases to the lungs, when, instead of a respiration which should be easy and uninterrupted, there is panting and wheezing, and stertor, and cough; and when, instead of the humid vapour which in health is separated by the bronchi, and mingles and glides forth with the breath, there is a hard and difficult expectoration of phlegm, of mucous or purulent secretion, or of blood.

But the direct symptoms which impute diseases to the lungs most unequivocally, and which make the most precise discovery of their nature and seat, are not of common or popular apprehension. There is a method by which the entire lungs, and each separate portion of them, can be scrutinized, and by which we can learn where respiration is perfect, and where it labours. It is the method of auscultation. And this method of auscultation does not merely discover a defect or failure of function in the lungs at this part or that, and so leave us to infer, from reasoning or from other circumstances, the exact nature of the disease (this, indeed, would be a great deal, and as much as the direct symptoms which respect the functions of parts are generally able to do); but auscultation often leads to more — discovering not merely the symptom, but the disease itself.

The excess and defect of bile, and various qualities of that secretion different from those of health, are the *direct* symptoms by which the liver shews itself morbidly affected. And the common consequences that immediately flow from impediments to the digestive function are the direct symptoms by which the stomach declares its complaint. Such are distentions, eructations, and rejected food, which has undergone the process of fermentation, and become acid and putrid: for these plainly shew that the substances submitted to the stomach have been left to suffer the chemical changes to which they are naturally obnoxious, the organ having lost its controlling power over them.

So, too, in the various changes which the urine is apt to suffer, in its excess and its defect, in the predominance of an acid or an alkaline quality, in its amorphous sediments and its chrystalline deposits, we have the direct symptoms which lead us to search for disease in the kidneys.

But each of these systems and organs requires from the student an express acquaintance with its natural functions, before he can be prepared to examine and appreciate their errors and defects; and then these errors and defects themselves he must expressly study, before they can yield him all the information which, as direct symptoms of disease, they are calculated to convey.

Now, whatever part be affected, when we bring our own knowledge of its disordered functions, and add it to what the patient tells us of its disordered sensations, we shall generally come somewhat nearer to a right notion of the seat and nature of the complaint; sometimes, indeed, to a *perfect* comprehension of it, so far as it is capable of being ascertained at all; inasmuch as there *are* conditions of disease into which no further inquisition can be made when we have learned the feelings and the functions of the part to which they belong.

Many of the local complaints which we are called upon to witness and to treat, are *not* of a nature to affect the structure of the part. In them it is not clear that there is any thing to be ascertained beyond the symptoms which respect its sensations and functions; whether, if the part were laid bare to us, and we could see and handle it, we should have any better notion of its complaint, or how to treat it. A man has a pain in his stomach, and he cannot digest, and yet he has no organic disease; and this being the case, I really do not comprehend how we are more

likely to learn the cause of the pain and the indigestion, or the proper method of its relief, seeing the stomach, than seeing it not.

But with all the knowledge of disordered functions which our best observation can furnish us, and all the knowledge of disordered sensations which the patient's faithful interpretation of his own feelings can supply; with all the light which sensation and function can, as direct symptoms, throw upon the disease of the part affected; still we often need *other* symptoms and *more* light to inform us what the disease really is, and what its treatment should be.

There is yet another order of direct symptoms besides those which *immediately* respect the sensations and functions of the part—viz. those which *immediately* respect its structure.

When parts are within reach of the sight or the touch, we can often judge whether their forms and structure be different from what they ought to be, and thus obtain direct evidence of their disease: and this evidence may be all that we require. What we see, or what we feel, may convey to us a complete knowledge of the disease, and render all consideration of other symptoms unnecessary. Sometimes these visible or tangible deviations from healthy structure are not only the direct symptoms expressive of the disease, but the disease itself.

In the morbid affections of external parts we can examine at once their state and structure, and learn in what respect they differ from what is natural; and the observation of this *direct symptom* almost supersedes the necessity of inquiry for any other; for herein we witness the very manner and process of the disease itself. We see the increased vascularity and tumescence which constitute inflammation, the lymph which is the material of adhesion, and the fluid which is the essential product of suppuration. We see all those sensible changes in the condition of the skin and cuticle which constitute the many orders and varieties of cutaneous diseases—rashes and vesicles, and pustules, and scales, &c.; in which it is obviously impossible to distinguish the symptom from the disease, or the disease from the symptom.

Again: we learn by the touch that the os uteri is changed in structure—that it is scirrhous, or that it is ulcerated, or that a polypus passes through it or grows from it: and here we have not only the palpable evidence of the diseases, but the diseases themselves.

But our business, as physicians, is chiefly with internal parts and organs; all of which are beyond the reach of our sight, and but a few perceptible to the touch; and these few only under certain conditions of disease.

Some organs of the abdomen, when disease has produced an increase of their natural bulk, become palpable through the integuments, and allow an examination of their shape and dimensions. But, after we have in this manner obtained such information as is possible respecting the structural condition of an internal organ, let us be careful to estimate it properly, and not to value it for either more or less than it is worth.

To ascertain by the touch that certain organs within the cavity of the abdomen have undergone an augmentation of their natural bulk—that the liver, or the spleen, occupy a space far exceeding that which nature has allotted them, beneath the cartilages of the ribs on either side—is, without doubt, to fix disease upon them. But it is not to determine the nature of the morbid processes which either are or have been in action within them. Finding the spleen enlarged, or the liver enlarged, we have the palpable result of some morbid action; but what that morbid action has been, and whether it is still in progress (the only questions which are pathologically or practically important), we must seek to discover by other symptoms. The increased bulk, then, of an organ, is a symptom, a direct symptom, of great value and certainty in fixing the *seat* of disease, but nothing more.

But it is by another sense that we are admitted to a much more intimate scrutiny of an internal part than any which the mere touch can afford, and thus obtain *direct symptoms* of its disease; which are often as infallible as those derived from sight itself.

By auscultation we not only become acquainted with the remote effects or ultimate results of morbid action, but often, when the disease is just doing its first rudiment of injury, the secret of its proceeding is betrayed to the ear.

The ear not only discovers the vomica or cavity which is the last of many changes wrought by tuberculous disease upon the structure of the lungs; not only finds their permeable texture converted into a solid mass by the gradual deposition (it may be) of tuberculous matter, or (it may be) of inflammatory lymph; but it can detect the first effusion into the vesicles of a single lobule which is produced by inflammation: it can detect pneumonia almost, perhaps altogether, simultaneously with its beginning to exist.

ST. BARTHOLOMEW'S HOSPITAL.

Row in the Operating Theatre—Excision of the left half of the lower Jaw.

On Saturday last a scene was enacted at St. Bartholomew's Hospital, which, for the credit of the profession, we hope will not be repeated.

Nearly all the students of the hospital had been attending Mr. Earle's clinical lecture, delivered immediately preceding the hour at which operations are performed, when, on quitting the lecture-room, and proceeding to the operating theatre, they found it occupied and actually besieged by a crowd of pupils not belonging to the hospital.

Mr. Earle addressed them, requesting them to give way and allow the students of the hospital to enter, at the same time promising that all who were medical students should be admitted after their own pupils had been accommodated. He further urged the impropriety and cruelty of their conduct towards the patient who was about to undergo a very severe operation, and was in a state of anxious suspense. It was in vain to remonstrate with them, as they resolutely kept possession, making a most disgraceful noise and disturbance close to the wards where the patients about to be operated on were waiting. His arguments being of no avail, Mr. Earle was obliged to declare that he would not perform the expected operation, and ordered his carriage to the door. After nearly an hour's delay, and by means of the active interference of the treasurer and beadles, the door-way to the theatre was cleared, which was soon occupied to an overflow. Among the visitors we observed M. Jules Cloquet and other distinguished foreigners, who, we fear, must have received a bad impression of the character of our medical students from witnessing such a scene as has been described.

The operation which had excited so much interest was the removal of one half of the lower jaw from a young man named Richard Garden, æt. 25, who was admitted on the 22d of October, with a large irregular tumor occupying nearly the whole of the left side of the lower jaw, extending from near the centre to the ramus, which was so much expanded towards the pterigoid processes of the sphenoid bone, that the exact boundaries of the disease could not be defined; but as the motion of the jaw was perfect, it was supposed not to extend to the articulation. A long elliptical incision was made from the centre of the jaw to about midway between the angle of the jaw and the external meatus auditorius. This incision exposed the edge of the masseter, and divided the facial artery; but this latter was not tied, as Mr. E. said he must divide it again below the jaw, where it emerges from the submaxillary gland. The integuments were carefully dissected downwards with the knife close to the enlarged bone; the submaxillary gland was detached, and the artery secured. A passage having been made in front, the bone was partly sawn through, and then divided with a very powerful pair of forceps. The bone was very hard and compact, and required much force to cut it through; but this was effected without any splintering, and presented a healthy even surface. The masseter muscle and parotid gland were next turned up, and the membrane within the mouth carefully separated. The greatest difficulty presented itself at the upper and inner part, where the ramus was expanded to the thickness of more than an inch. The walls of the tumor were, however, thin at this part, and partly with a strong knife, and partly with the forceps, the tumor was cut through near its upper extremity. The contents of the bony tumor came away entire, but a small portion of the bony cyst was left, with a thick vascular membrane lining it; this membrane was easily detached, and the remaining portion of the bony walls was subsequently removed. In all, four arteries were tied; and as the bleeding had nearly ceased, the divided integuments were approximated with three hare-lip pins and two common sutures. The patient complained of severe pain in his ear, which subsided after two doses of opium.

He has continued to go on most favourably; and when the sutures were removed on the Tuesday, the entire wound was found perfectly united. He has had a very profuse flow of saliva, tinged with blood, and suffers little or no pain, being able to speak and swallow without difficulty.

The tumor, which was nearly three inches in thickness, consisted of the expanded walls of the inferior maxillary bone, lined with a thick vascular cyst, which contained a mixed structure, in part approaching to fungus, but in others having a fibrous character, with some portions of bone running irregularly into its substance. On the upper and outer surface the bony cyst was so thin that it yielded to pressure, and conveyed an impression to the finger like a portion of thick parchment.

Mr. Earle stated, before the operation, that he once met with a case in which this same sensation could be felt, and which proved to be a thin bony cyst containing a

fluid, and a tooth which had taken a wrong direction; in which case it was only necessary to pare off the bony cyst from the surface of the jaw, and the case terminated well; but in the present case the tumor extended so far beneath the tongue, and towards the basis cranii, that he could not expect to meet with a similar state of parts, although the sensation conveyed to his finger was precisely similar.

When the above operation was concluded, Mr. Stanley removed a large pendulous cellular tumor from the labium of a female, similar in structure to some cases related by Mr. Lawrence, in the Medico-Chirurgical Transactions.

THE POOR LAW SYSTEM.

QUERIES ADDRESSED TO PROVINCIAL PRACTITIONERS REGARDING PAROCHIAL MEDICAL RELIEF.

To the Editor of the Medical Gazette.

Sir,

At the last anniversary of the Provincial Medical and Surgical Association held at Oxford, a committee was appointed to consider and report on the best means of affording medical relief to the sick poor, especially with reference to the Poor Law Amendment Act.

As secretary to this committee I am desired to solicit you to further their objects by inserting the present communication, and by supporting it with such arguments as your own just views of the subject may suggest.

The lamentable effect of recent measures both on the sick poor, and on the medical profession, and the determined attempt to *continue* and *justify* them, evinced by the last report of the Poor Law Commissioners, (dated Aug. 8th, 1835) demand the most decided and unanimous conduct on the part of the profession: our opposition will, however, possess but little *moral* force if it be not supported by substantial *reasons*; and these reasons can only be deduced from a correct and ample compilation of *facts*, which are but too frequently to be met with where the new law has been carried into effect.

These considerations will, we trust, induce our professional brethren, residing in those parts of the kingdom already under the operation of the Poor Law Amendment Act, to supply us largely with answers to the subjoined queries: by so doing the labours of the committee will be rendered more efficient, and it is hoped that in consequence a more suitable, more just, and more humane system of parochial medical relief, may be adopted.

[The questions are addressed to individual country practitioners.]

1. What has been the mode of appointing and paying medical officers of parishes in your neighbourhood for the last few years?

2. Has any alteration in the above mode taken place since the introduction of the Poor Law Amendment Act?

3. Are an *equal number* of medical men provided for the poor as formerly?

4. What is the *population* or extent of the district or districts entrusted to one medical officer?

5. What is the *greatest distance* of patients from the medical officer? and is that greater or less than under the old system?

6. How are *orders* for medical relief obtained in ordinary cases? and how in urgent?

7. Have *tenders* been required? and have they been furnished? and to what extent?

8. What are the amounts of the stipends? are they fixed annual sums? or payments *per case?* If the latter, is any gradation according to the numbers or distance of the patients allowed? and is any limitation to the sum total exacted?

9. Are the forms of the contracts in any of their clauses degrading to the respectability of the profession?

10. Have there been any instances of distress and danger to the sick poor? and to what *direct* causes are they attributable?

11. Are there any other particulars bearing on any of the above questions, which occur to you as worthy of remark?

As the prosecution of this inquiry is likely to be attended with considerable expense it is suggested that, on public grounds, communications addressed to the secretary should be post paid.—I am, sir,

Your obedient servant,

H. W. Rumsey.

Chesham, Oct. 26, 1835.

HENDERSON'S EDITION OF CUVIER.

GROSS BREACH OF ENGAGEMENT WITH THE SUBSCRIBERS.

To the Editor of the Medical Gazette.

Sir,

The following is, perhaps, one of the grossest booksellers' jobs that has ever been perpetrated in this country, and should be exposed in the most public manner.

In the course of last year, Mr. Henderson, of No. 2, Old Bailey, issued the first number of a translation of Baron Cuvier's

Animal Kingdom; upon the cover of which appeared the following address:—

"The work will consist of 36 numbers; each will be sold at one shilling. It will appear uninterruptedly the first of every month, and the contents will be letter-press and plates."

The work accordingly proceeded agreeably to the advertisement to the 14th number, but now two numbers (14 and 15) were united, and issued as one, price two shillings; which experiment of the publishers succeeding, they grew more bold, and on the cover of the 22d and 23d numbers appended the following address:—

"The public will immediately see, that according to the ordinary plan of issuing the plates which illustrate 'Cuvier's Animal Kingdom,' the proprietor could never fulfil his engagement and supply the complete quantity. He begs, therefore, to apprise the public that he will take the opportunity, during the ensuing months, of preparing numbers which shall consist wholly of plates."

Accordingly, when they arrive to No. 28, they lay aside the disguise of calling each part two numbers, and boldly issue No. 28, and each succeeding number, at the advanced price of two shillings.

On arriving at the 57th number, the following impudent address appears on the envelope:—

"The proprietors of 'Cuvier's Animal Kingdom,' which is now completed, in so far as the body of the work is concerned, have to intimate to their numerous subscribers that there will be appended to it, besides a general alphabetical Index of its contents, a careful, concise, and comprehensive synopsis of all the matter found in the work, which will form in itself a complete compendium of the 'Animal Kingdom.' There will also be published an explanation of the plates, in a separate form, so as to afford an opportunity of having them bound up with the work, or otherwise, as circumstances may suggest.

"The proprietors have also to state, that in every succeeding number there will be twelve plates, until the whole are published, without any addition being made to the usual price."

Now it might be expected, from the above address, that the work really was completed, and that the succeeding parts were merely designed to render it more complete; which the purchaser might or might not choose to possess: but no such thing; not only is the text not completed, but in the very last numbers which have appeared (74, 75, and 76) are the following plates:—"Over, pl. 2, 5, 6, 11, 14, 19, 20, 21, 22, &c. &c."—besides several of the early plates, relating to classes Pisces and Mammalia.

The manner in which the work has been thus spun out is as follows:—The proprietors have found no difficulty, out of the innumerable varieties of the animal kingdom, to get up a succession of cheap plates, illustrative of the varieties of the species; which, however, are wholly unnecessary for the illustration of the text. Thus there is Pl. 33, Pl. 33, bis; Pl. 33, ter., Pl. 33, quarter, &c. &c.

Now, sir, I appeal to any one, whether it is not a gross imposition to be obliged to pay 6*l.* 4*s.* (and God knows how much more before the work is completed) for what was originally announced for 1*l.* 16*s.*? But I call upon the proprietors, not merely in the tone of indignant complaint, but for the further purpose of bringing them to deserved punishment. It is my fixed determination to call upon them in a court of law to disgorge their ill-gotten gains; and it is for this purpose that I now call on you to expose the job, in order that other subscribers may come forward, and make common cause with myself against imposition.—I am, sir,

Your obedient servant,

P.

November 4, 1835.

DEATH BY VOLUNTARY ABSTINENCE—MEANS OF PREVENTION.

Morey, the supposed accomplice of Fieschi, is said to have determined to die of inanition. Grave questions are raised by some of the French journalists whether he ought or ought not to be *forced* to take food: some of them doubt whether it were even justifiable to introduce alimentary matter into his stomach by the gum elastic tube. In this country, we believe, there would be no hesitation in preventing a man from committing *suicide,* no matter in what way he proposed to effect his purpose: the law here does not allow a British subject to make away with his own life. We wish a simple method were tried on M. Morey, which has been suggested by a French practitioner—namely, to place him on his back, keeping his head steady, and then to pour down his nostrils some nutritive liquid: it would reach the pharynx at once, which would involuntarily contract upon it, and convey it along the gullet. Not a drop would get into the air-passage if the head were only kept steadily fixed.

ISSUE OF THE *DE VENTRE INSPICIENDO* CASE.

Mrs. Ann Fox, in whose case the ancient and indecent writ for ascertaining the existence of pregnancy was sought to be revived (see our last vol. p. 697), was delivered of a son and heir a few weeks since.

DEATH OF SIR DAVID BARRY.

It is with much regret that we have to announce the sudden decease of this gentleman, which took place on the morning of the 5th, at his house in Welbeck-Street.

Sir David was seized on Wednesday, about one o'clock, when walking in the Haymarket, with extreme faintness, and was carried into a shop. Dr. James Johnson was immediately sent for; but being from home, Mr. H. J. Johnson went to his assistance, and had Sir David taken home in a coach, when messengers were dispatched for Dr. Copland and Mr. M'Intyre. All the above-named gentlemen arrived soon after, by which time their patient had rallied considerably. He complained of pain in the belly; and having eaten some fruit on the preceding day, which was supposed to have disagreed with him, a warm cathartic was administered. The bowels were moderately acted upon in the course of the evening, and he was seen by some of his attendants at ten o'clock, apparently better. There was then no tenderness about the abdomen; his pulse 84, and natural; and his own impression that he had been seized with some mortal affection, which had at first existed, had passed away. He stated, however, that he experienced an odd kind of uneasiness in the belly on turning himself in bed, and his breathing was observed to be rather short. He requested to have something to take in case of again becoming faint; which request was accordingly complied with. A few minutes past one in the morning he had occasion to get up, uttered an exclamation that he was dying, and instantly fell back in his chair, dead.

The body was examined on the evening of the 6th, when the cause of death was found to have been an aneurism of the descending portion of the thoracic aorta. It had burst into the mediastinum, and thence into the right thoracic cavity, which contained an immense quantity of blood.

Sir David Barry was in his 56th year. He was for some years in the medical department of the army—originally, we believe, in the Portuguese service. Latterly he had been a good deal employed by government in investigating the subject of epidemic diseases, particularly yellow fever and cholera; in regard to the latter of which he was a strong contagionist.

ROYAL COLLEGE OF SURGEONS.

The announcement in our last number, regarding the recent election, was incorrect. Mr. Green obtained his seat in the Council on the resignation of Mr. Lynn. The vacancy caused by the death of Sir William Blizzard, has been filled up by the election to the Council of Mr. Callaway. The vacancies which simultaneously occurred in the Court of Examiners were filled,—the former by Sir B. Brodie, and the latter by Mr. Samuel Cooper.

We are compelled, by want of space, to omit for this week the List of Gentlemen who received Diplomas at the College of Surgeons last month; also the names of those to whom Certificates have been granted by the Society of Apothecaries.

Prevailing winds, S.W. and S.E.

Except the 27th and 28th, generally cloudy, with frequent showers of rain.

Rain fallen, 1 inch and ·3 of an inch.

Charles Henry Adams.

NOTICES.

We are obliged to Mr. Foote for his information, but we had anticipated him.

"A. B." should have authenticated his letter; at least confidentially.

"Expertus" might have saved himself the trouble of writing his puffing letter about a new publication; it was quite enough to have received one from the author himself. We shall notice the work in due time, should it prove deserving of that attention,—which we very much doubt.

The letters and papers of several correspondents, which have been unavoidably postponed, shall make their appearance next week.

Wilson & Son, Printers, 57, Skinner-St. London.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE VII.

AT our last meeting I took a brief general survey of the different methods of arranging the articles of the materia medica, and at the same time offered a few examples of each mode of classification: I also stated my intention of following in these lectures the natural-historical method; but as I shall, hereafter, have frequent occasion to refer to the effects of those generally admitted classes, formed by associating medicines operating on the body in an analogous manner, I have thought it necessary to premise a short account of them, and thereby to save much subsequent repetition.

Class I. *Cerebro-spinants.* — The first class to which I must beg your attention is one consisting for the most part of the substances usually called narcotics. There are, however, several which cannot be termed narcotic, since they do not stupefy, but which, notwithstanding, I think, ought to be associated with them;—I allude now to strychnia and brucia. I propose, therefore, to include them all in one class, under the name of *cerebro-spinantia*, or agents acting specifically on the cerebro-spinal system.

The cerebro-spinants are found among mineral, vegetable, and animal substances, but those employed in medicine are almost exclusively vegetable, and are derived from the families, papaveraceæ, solaneæ, apocyneæ, umbelliferæ, ranunculaceæ, scrophularineæ, and amygdaleæ. For example, opium, hyoscyamus, stramonium, belladonna, tobacco, nux vomica, strychnia, conium, aconite, digitalis, and hydrocyanic acid. There are many substances which act on the cerebro-spinal system, though they are not employed in medicine as such, since to produce this effect they require to be given in such large doses that we thereby compromise the safety of our patient from the irritant operation. I may mention as examples, squills, veratrium, colchicum, and arsenic.

The local effects of the cerebro-spinants are far from being uniform: several of them diminish the sensibility of the parts with which they are placed in contact, and thus deaden pain: some even produce numbness, as monkshood, when applied to the lips, or hydrocyanic acid vapour to the fingers. Opium and others lessen the contractile power of muscular parts, and thus relieve spasm. In poisonous doses many of them act as powerful local irritants, and in toxicological classifications they form the class acro-narcotics. I may mention as examples, belladonna and stramonium. We take no advantage of this effect in therapeutics.

The remote effects of cerebro-spinants vary with the particular substance employed: some primarily excite the vascular system, others appear to have an opposite effect, and are, in consequence, termed *sedatives.* The only point in which they all agree is in their primary and specific influence on the nervous system. But the modifications which they producein the functions of this system, vary with the individual agent, so that we are not far from the truth in asserting that each has its own peculiar and specific mode of action on the organism, and, consequently, that no one precisely resembles another in the nature of its effects. It is, indeed, true, that some have a greater similarity in their mode of operation than others, but when

we examine them closely, we find distinct individual peculiarities. Hence, then, in describing their effects, we must proceed in generalities, for, if we attempt to descend into particulars, many remarks could only be applicable to some of these agents. The difficulty of describing the operation of this class is still further increased by our knowledge of the fact, that the same cerebro-spinant operates unequally on different persons, and in different doses. I think, however, it will be useful to group those whose effects are for the most part analogous, and which are employed in medicine for similar purposes; but no classification of them will invariably hold good.

1. The *first group* we may denominate the *opiate*, or *stupefying*; it includes the narcotics properly so called; for example, opium, hyoscyamus, and lactuca. In small doses they produce symptoms of excitement; in larger ones we find diminished sensibility, muscular contractility, and sleep or stupor, are the ordinary effects. In great quantities the phenomena are similar to those of apoplexy, and constitute what is called *narcotism*. These symptoms point out the uses of the group; in small doses to excite, in larger ones to diminish excessive sensibility, and relieve pain, hence they are called *anodynes* (from *α*, *not*, and *οδύνη*, *pain*); or *paregorics* (from *παρηγορεω*, *to soothe* or *alleviate*), to diminish inordinate muscular contractions, as convulsions or spasm (the first affecting the voluntary, the second the involuntary muscles,) and to procure sleep, whence they have been termed *hypnotics* (from *υπνωτὶκος*,) or *soporifics* (from *sopor*, sleep, and *facio*, to make).

2. The *second* we may designate the *strychnos*, or the *tetanic group*. It includes all substances whose active principle is either strychnia or brucia, or both of these alkalies; namely, nux vomica, St. Ignatius's bean, the lignum colubrinum and false angustura bark. The mental faculties are by this group unaffected; and the principal symptom is tetanic convulsions. The sensibility of the body is so far affected that the slightest touch will frequently bring on a violent convulsive paroxysm. Certain facts hereafter to be detailed, lead us to infer, that the action of these substances is confined to the spinal marrow. We employ this group principally in paralytic affections, more especially where these are unaccompanied by any organic changes of the nervous system, as in paralysis by lead. This group is by Cottereau formed into a distinct class, under the name of *tetanics*. If this be admitted, and the term narcotic applied to stupefying agents only, as opium, where ought cocculus indicus and other agents to be placed, which produce both tetanus and stupor? It appears to me the tetanics pass so insensibly into the narcotics commonly so called, that the two ought to form only subdivisions of one class.

3. The *third* or *hydrocyanic group* comprehends all substances whose active principle is hydrocyanic acid. We must, however, extend this definition, since it has been found that several vegetables which yield this acid, and are energetic poisons, do not contain it as their active principle, but that they have some other substance whose effect is analogous, and which is easily converted into it. In this group we include the bitter almond and essential oil obtained from it, the cherry laurel, &c. This group contains the poisons which are the most rapidly fatal of any known. In large doses they produce sudden death preceded by convulsions and insensibility; in smaller ones they act as *sedatives*; that is, they diminish action without causing any previous excitement. They are used in therapeutics to diminish what is called "morbid irritability" of the pulmonary and alimentary organs.

4. The *fourth* or *acro-narcotic group* contains belladonna, stramonium, conium, and aconite. This is by far a less perfect group than the three preceding ones. In poisonous doses they excite more or less local irritation, an effect particularly observable in aconite. Hence, while the three first are called acro-narcotics, the fourth is frequently termed a narcotico-acrid. Their effects on the nervous system are variable; but delirium is a frequent symptom, sometimes stupor, and occasionally convulsions. Their uses in medicine are various: belladonna is principally employed to dilate the pupil and to relieve neuralgic pains; hemlock to diminish sensibility in painful diseases.

5. The *fifth group* agrees in several points with the fourth. Thus, in poisonous doses, we find symptoms of local irritation; delirium, stupor, and convulsions, also occur. But the peculiarity of this group is the depressing effect on the arterial system; marked by faintings, feebleness, and irregularity of pulse. Tobacco and fox glove are the only substances which belong to it. They, therefore, are ranked among *sedatives*. When given in large doses, the first causes great feebleness of the muscular system, the second sometimes salivates. Both (but especially fox-glove) are employed to reduce arterial action, and tobacco on account of its purgative effect.

In addition to these we might make two other groups; one called *inebriants*, the other *nervines*: but I shall notice them under the head of stimulants.

The immediate cause of death when the

cerebro-spinants have been given in large quantities is not always the same: sometimes it would appear that the respiratory muscles do not receive their proper supply of nervous energy, in consequence of which this function is performed with increasing difficulty until ultimately death takes place from asphyxia. This is the kind of death caused by opium, and sometimes by dilute hydrocyanic acid. Before the cessation of life you observe the breathing becomes laborious or even stertorous, as in cases of apoplexy; and if you open the body immediately after death, the heart is found beating oftentimes with considerable force and for some minutes. [A rabit was killed by hydrocyanic acid, and the fact shewn.] These are the cases in which it has been proposed to prolong life by artificial respiration until the cerebral disorder has passed off. The proposition is not supported merely by its ingeniousness and plausibility, but by experience. The following is a case in point related by Mr. Whateley, and quoted by Dr. Christison in his work on Poisons. A middle aged man swallowed half an ounce of crude opium, and soon became lethargic. He was roused from this state by appropriate remedies, and his surgeon left him. But the poison not having been sufficiently discharged, he fell again into a state of stupor; and when the surgeon returned, he found the face pale, cold, and deadly, the lips black, the eyelids motionless, so as to remain in any position in which they were placed, the pulse very small and irregular, and the respiration quite extinct. The chest was immediately inflated by artificial means, and when this had been persevered in for seven minutes, expiration became accompanied with a croak, which was gradually increased in strength till natural breathing was established; emetics were then given, and the patient eventually recovered. I have several times restored animals apparently dead from the use of hydrocyanic acid, merely by keeping up artificial respiration, and Sir Benjamin Brodie has done the same with animals apparently killed by the oil of bitter almonds.

In some cases the immediate cause of death is believed to be paralysis of the heart. The grounds for this belief are, the cessation of the heart's action (in some instances even before the animal had ceased to respire); on examination after death, the heart is found distended, the left side with scarlet, the right side with dark-coloured blood. Sir Benjamin Brodie says the infusion of tobacco kills dogs and cats in this way. I have frequently tried the effect of the infusion on rabbits, but have found death is produced, as I believe, from the stoppage of respiration. [The lecturer threw an infusion of tobacco into the peritoneal sac of a rabbit: in a few minutes the animal was so far paralysed as to be incapable of standing, and its breathing became short and quick. Shortly afterwards convulsions came on, in which the animal died. On opening the chest the heart was found still beating, though much more feebly than in the animal killed by hydrocyanic acid, and all the cavities were remarkably distended with blood.] On the supposition that tobacco kills by paralysing the heart, we have been recommended to stimulate this viscus by slight galvanic shocks. Even acupuncture has been talked of as an admissible remedy, if the patient appeared to be *in articulo mortis.* I may remark, that Bretonneau has fully established the fact that we may acupuncture the brain, the heart, the lungs, &c. of animals without any inconvenience; and Carraro, an Italian physician, has successfully tried this practice on animals that had been asphyxied.

A third mode of death from cerebro-spinants is that arising from suspended respiration produced by convulsions of the respiratory muscles. We have an example of this in strychnia, brucia, and all substances containing them. If I introduce half a grain of strychnia into the peritoneal sac of this rabbit, you will observe that death will take place within seven or eight minutes, and, as far as we can judge from the convulsions which are excited, stopping respiration. [The experiment was performed; the animal became convulsed in six, and died in eight minutes.]

There are many points of considerable interest in reference to the operation of cerebro-spinants, which can only be answered hypothetically or theoretically. One is the pathological condition of the brain and spinal marrow; and whether the peculiarities in the operation of different cerebro-spinants arise from different parts of these organs being affected, or from different modes of affection: in other words, whether the peculiarities depend on variations of *locality* or of *quality* of operation. I think it must be concluded that opium operates principally on the cerebral, strychnia on the spinal, functions. But what may be the particular pathological condition of the brain or of the spinal marrow, induced by these poisons, we have not sufficient evidence to enable us to form any well-grounded opinion. There are, however, several reasons which lead us to suspect that opium produces a congested state of the cerebral vessels. Possibly other cerebro-spinants may give rise to a similar condition, but as each has a peculiarity of effect, so there must be some other conditions accompanying

this, and which is probably the cause of its peculiarity.

Another interesting subject of inquiry is the probability or otherwise of the absorption of cerebro-spinants. The active principles of many of them are not detectable, by physical or chemical means, either in the blood or secretions, so that we are deprived in these cases of positive evidence. Barbier states that the odorous matter of opium has been detected in the urine, in the sweat, and in the liquor exhaled by the pleuritic membrane; and the same author tells us that the milk of a nurse who had taken opium was narcotic. Hydrocyanic acid has also been detected in the blood and other parts of the body. That some cerebro-spinants, therefore, get into the blood is indisputable, but whether others do, we have not at present the means of determining.

But even if it were proved that the active principles of all get into the blood, it cannot be proved that the effects are the consequences of the absorption. They may be the *post hoc*, and not the *propter hoc*. The excessive rapidity of the action of strong hydrocyanic acid appears almost inconsistent with the notion of its previous absorption. Lastly, if we had good reasons for concluding that the effects of cerebro-spinants arise from their absorption, we have yet to learn the relation of the two series of phenomena—the absorption and the consequent effects. The whole subject is involved in such obscurity, and the positive facts are so few, that we can offer no theory of any great value or importance.

Class II. *Stimulants, Excitants, or Calefacients.*—The next class of substances which I propose examining is that called by some *stimulants*, by others *excitants* or *calefacients*, and which includes a considerable number of substances exceedingly difficult to characterize generally. They have all a warm, acrid, and pungent taste; and in most cases are more or less odorous, frequently in consequence of the presence of volatile oil. When swallowed in moderate doses they increase the appetite, give rise to a sensation of warmth in the stomach, expel gaseous matters and assist digestion. In larger quantities they sometimes irritate, excite nausea, and even vomiting, and produce thirst. Several of them appear to confine their operation to the alimentary tube (the carminatives), while others affect the whole vascular system, increasing the force and frequency of the heart's action, and in consequence raising the temperature of the body, and augmenting the number of respirations in a given time.

The local action of this class of substances is not uniform: many of them powerfully affect the organ of smell, as ammonia, æther, musk, the labiate plants (as the mints,) the fruit of umbelliferæ (as caraway, aniseed, &c.) laurineæ (as camphor, cassia, &c.) When applied to the skin in a concentrated state and for a sufficient length of time, some of them produce heat, redness, pain, and swelling; and if the application be persisted in, suppuration, vesication, or gangrene. As the general system is not always affected in proportion to the degree of local irritation produced, so this latter is not regarded as essential to the stimulant operation. The labiate plants have very little power of irritating or inflaming, though they act on the nerves of the tender and delicate parts, as the lips.

The classes stimulants and cerebro-spinants are closely connected. Nutmegs, for example, which are generally classed among stimulants, have a narcotic operation. Musk, valerian, and some other usually admitted stimulants, affect the cerebro-spinal system apparently in a specific manner: these agents have in consequence been called by some *nervines*. On the other hand the cerebro-spinants frequently partake of the stimulant character. Opium indeed is often employed by persons in health on account of its exciting effects. The substances usually denominated *inebriants*, as alcohol and æther, are also examples of cerebro-spinants possessing a marked stimulant operation.

Stimulants, by affecting the general vascular system, excite the secreting and exhaling organs, and thus they are frequently denominated sudorifics, diuretics, emmenagogues, expectorants, &c. As I have grouped the cerebro-spinants, I shall attempt the same with this class.

Group 1. This contains the *Acrid stimuli* used to assist the digestive process, under the name of *condiments;* but which, when given to expel wind and relieve spasmodic pain, are termed *carminatives.* This group includes the spices, as ginger, the peppers, cassia, cinnamon, cloves, pimenta, canella, &c.; the fruit of the umbelliferæ (as fennel, caraway, aniseed, dill, and coriander); the labiate plants (as the mints); and the agents frequently termed antiscorbutics, consisting of certain volatile vegetable stimuli derived from the families cruciferæ and asphodeleæ, (as mustard, horse-radish, leeks, onions, garlic, &c.)

Group 2. *Resinous stimuli,* comprehending the balsamic substances, or those containing benzoic acid, as tolu, peru, benzoin, and styrax; the solid resinous substances, as olibanum, mastic, and guaiacum; and liquid resins, or those composed of volatile oil and resin, as the turpentines.

Group 3. This contains the *diffusible*

and *fœtid* or *antispasmodic stimuli.*—Here we place the fœtid gums, (asafœtida, galbanum, sagapenum, opopanax, ammoniacum, and myrrh); the animal substances, musk and castoreum; empyreumatic oils, ammonia, alcohol, æther, &c.

Class III. *Tonics.*—I proceed now to notice *tonics*, a class of substances having considerable importance in practice, but the operation of which is very imperfectly understood. They have received their name from *τονος, tone* or *vigour*, being supposed to strengthen and invigorate the body. In this sense, however, all substances contributing to the support of the vital powers are tonics; nutrients, nay, even evacuants, may be regarded as indirectly so; since without the former life cannot be supported, and the latter by removing diseases tend to prolong it: but it is well known, in the common acceptation of the term tonic, neither of these classes of substances are intended to be included. Nutrients only strengthen by becoming digested and assimilated, whereas the digestion and assimilation of the active principle of a tonic would render it inert.

Tonics do not invariably strengthen: in some cases no obvious effects are observed by their exhibition, in others they act as irritants and stimulants. We have, therefore, still to learn what is their constant and invariable action. The strengthening or corroborant operation is observed only when the body is preternaturally weak, though not always even then. In the state of health no obvious effect is produced, except occasionally a temporary excitement of the appetite. Even in debilitated states of the system this is sometimes the only result from one or two doses. In order to produce the tonic effect on the system generally, these agents require to be exhibited for some time. We then sometimes find the muscles acquire more power, the solids become firmer, and all the functions are performed with more energy. The pulse is rendered stronger, but without being quickened; and the patient is capable of greater exertion than before.

If there be irritation or inflammation of the alimentary canal previous to the exhibition of the medicine, or if some febrile disorder be present, accompanied with a hot and dry skin and a furred and dry tongue, tonics will only add to the severity of the symptoms: they then act as irritants or excitants. In weakly and irritable subjects I have frequently seen the sulphate of quinia cause headache, and give other evidence of its action on the nervous system. These facts shew that tonics are stimulant powers; indeed it is not easy always to distinguish the classes tonics and stimulants from each other. They mutually approach and gradually pass the one from the other, so that many substances may with equal propriety be arranged under either head.

The true tonics are of vegetable origin; animal and mineral ones are indeed mentioned, but it is doubtful whether any of them deserve this name. The only animal substance which has been employed as a tonic is the extract of ox bile, which still constitutes an article of the materia medica in some of the continental pharmacopœias. A considerable number of mineral substances are termed tonic, though there appears to me but little ground in most instances for such designation. For example, the preparations of arsenic, silver, copper, bismuth, zinc, &c. have all been called tonics, and principally for the following reason: cinchona, the most powerful of the vegetable tonics, and in fact the type of the class, has long been celebrated as a curative agent in ague and other periodical diseases; hence it has been assumed that any substances capable of fulfilling the same indication must be possessed of the same properties, and thus arsenic has been called a tonic. But the mode of reasoning and its conclusion are both erroneous; it is indeed true that cinchona and arsenic have in common the power of curing an ague, but the same effect is frequently produced by many other very dissimilar substances: for example, blood letting, alcohol, and mental affections. If, therefore, arsenic be called a tonic for the above mentioned reason, these agents must be similarly denominated. If we admit this, it follows tonics can no longer be regarded as substances promoting strength, but merely as agents curing particular diseases. Before we have any right to associate arsenic among tonics, we must completely alter our definition of these substances, or show that arsenic improves the appetite and promotes strength to the body. Iron is almost the only metallic substance that can claim with any shadow of propriety the tonic property.

The mineral acids agree with the vegetable tonics in increasing the appetite, but the effect is only temporary, for by continued use, instead of improving they injure the digestive functions, thereby differing considerably from the vegetable tonics.

By many writers on the materia medica the substances called *astringents* are formed into a class separate from that of tonics. They are supposed to be distinguished by the contraction and corrugation they produce in the tissues to which they are applied, and which has been termed astriction. Thus they contract and give greater density to the muscular fibre, and diminish the calibre of the blood-ves-

sels and exhalents of the parts with which they are placed in contact.

When used to check hæmorrhage they are called *styptics*. Applied to the tongue they give rise to a peculiar sensation of roughness and stypticity. All vegetable astringents, however, are tonics: that is, they increase the appetite, promote digestion, and are capable of fulfilling the same therapeutic indications (as curing the paroxysms of an intermittent fever.) But mineral astringents and styptics are not tonics.

The vegetable bitters have the property of retarding the process of fermentation, and hence may be useful in dyspepsia, where there is a disposition to acidity and flatulence. The beneficial effects sometimes obtained in verminous diseases by the use of bitter and ferruginous preparations, has by some been referred to a poisonous operation excited by these agents on intestinal worms, a notion thought to be supported by the fact, that infusion of quassia is destructive to flies, and that the *amer* of Welther (now called carbazotic acid) is asserted by Emmert to be poisonous to fowls and lizards. But according to the experiments of Redi, bitters are not an immediate poison to worms. Baglivi mentions that a saturated infusion of wormseed (semina santonici) killed an *ascaris lumbricoides* in five hours (Redi says between seven and eight hours,) but that a much more bitter decoction of absinthium required thirty hours. Hence it is quite clear that it cannot be by its bitterness that the wormseed operates as an anthelmintic.

The local effects of the astringent tonics have by some writers been attributed to a physical or chemical agency. Dr. Cullen, for example, places astringents under the head of medicines acting on the simple solids, though in another part of his work he admits that they act on the living likewise. The late Dr. Adair Crawford supported the same opinion of the physical agency of tonics, and endeavoured to prove it by experiment. He immersed pieces of intestines, skin, &c. in various bitters and other infusions, and some in water merely; he then observed the comparative weights required to break them. From these data he inferred that bitters increase the strength of the intestines in the following order: Peruvian bark, galls, chamomile flowers, gentian root, columba root, cascarilla, myrrh, and serpentaria; but this mode of reasoning naturally leads to erroneous inferences, since the vital powers of the system are totally overlooked, and in the second place the tonics may have acted in this case merely as antiseptics.

We may establish the following groups of tonics:—

Group 1. *Simple vegetable bitters*, including gentian, quassia, columba, simaruba, willow bark, Iceland moss, &c.

Group 2. *Pure astringents*, as catechu, kino, nutgalls, oak bark, uva ursi, rhatany root, &c.

Group 3. *Astringent bitters*, as cinchona.

Group 4. *Aromatic bitters*, as cascarilla, chamomiles, &c.

Group 5. *Mineral tonics*, as iron.

Class IV. *Emollients.*—The substances called emollients next claim our attention, their action being precisely opposite to that of astringents, as they produce relaxation and weakness. Applied to inflamed parts they diminish heat, tension, and pain; they have a relaxing influence on the muscular fibre in a spasmodic condition. When used to prevent the action of irritating matters on the body, they are called *demulcents*. Mucilaginous, feculent, oleaginous, and saccharine substances, are in their local effects emollients; when digested they are nutrients.

During life, the particles of the body are kept in approximation by two forces, attraction and the vital principle; and as emollients cause relaxation, it has been supposed by some, that they do so by overcoming the cohesion of the molecules independent of the vital principle. Thus we know that warm water and oil relax dead matters (as leather), and in consequence it has been thought that they influenced living parts in the same manner, and therefore, that emollients were physical agents. But we should always be cautious in applying physical explanations to vital phenomena. In the present instance the reasoning does not appear good. It is indeed true that some emollients act as relaxants to inorganized matters, but the reverse is not the case: all relaxants are not emollients. Cold water diminishes the cohesion of dead animal matters, but not of living tissues, and the same remark applies to many other agents.

Class V. *Refrigerants.*—Refrigerants constitute another class of medicines. Various substances are used in medicine to diminish the temperature of the body when preternaturally increased, under the name refrigerants. The only agent that can with propriety bear this appellation is cold used in the form of ice, cold air, cold bath, cold lotions, cold drinks, &c. However, acidulous vegetable matters, the dilute mineral acids, the super-salts of the alkalies, and some of the neutral salts, have been used for a similar purpose.

We can readily understand the agency of cold as a refrigerant, but it is not easy to say how the latter mentioned substances can have the effect here supposed.

Class VI. *Sudorifics or Diaphoretics.*—Dia-

phoretics or diapnotics are those agents supposed to promote the insensible perspiration, while sudorifics are those that produce sensible perspiration or sweat. It is highly probable that the insensible perspiration and sweat differ from each other chiefly in their physical conditions, the first being in the vaporous form, the second in that of the liquid; though it is stated that sweat contains less carbonic acid and more salts than the insensible perspiration, but the difficulty of obtaining the latter for examination, renders any assertions of this kind very doubtful. If the cutaneous exhalation be moderate it is rapidly converted into vapour; but should it take place faster than the atmosphere can carry it off, either from the increased cutaneous transposition, or from an alteration in the hygrometric state of the air, an accumulation on the skin takes place in form of drops, called sweat. There is then no essential distinction between diaphoretics and sudorifics; indeed the same substances may be either the one or the other according to circumstances. Heat and diluents are the most powerful diaphoretic or sudorific agents, but a variety of stimulants are employed as such; for example, ammonia, guaiacum, mezereon, &c. A variety of solid substances have been used as media for the application of heat: hot sand is a very old remedy, being mentioned by Celsus and Dioscorides; bran, ashes, earth, and plaster, have also been employed. The inhabitants of Crimea employ the saline mud found on the sea-shore: hot dung is used in France against rheumatism, and by the Poles against syphilis. The husk of the grape and the refuse of the olive, from which the oil has been drawn, undergo fermentation, and in this state have been successfully employed in Paris against rheumatism. Water in the liquid or vaporous form, and dry air baths, are powerful sudorific agents. Frictions, warm clothing, exercise, and cold affusion, are among other means of promoting diaphoresis.

The opinions of Dr. Edwards regarding the manner in which cutaneous transpiration is effected, seem to require a slight notice here. According to this physiologist, cutaneous transpiration is effected in two ways: 1, by a physical action or evaporation; 2, by an organic action or transudation. The first is the consequence of the porosity of bodies, and takes place equally in the dead and living state. It is influenced by the hygrometric states of the surrounding air, by its motion or stillness, by its pressure, and by its temperature. Thus dryness, agitation, and diminution of the weight of the air, increase this mode of transpiration. Transudation, or the organic action of transpiration being a vital process, depends essentially on causes inherent in the animal economy, although it may be influenced to a certain extent by external agents. Thus elevating the temperature of the surrounding air, preventing its frequent renewal, and covering the patient with warm clothing, are means which promote this organic action, but which check the physical operation of transpiration. When, therefore, we speak of diaphoretics and sudorifics, we mean agents which promote the vital actions of the extreme exhaling vessels of the skin, by increasing the general force of the circulation, or exciting the cutaneous vessels. Ammonia, violent exercise, alcohol, &c. act by increasing the vascular action generally: whereas heat, friction, &c. operate by exciting the cutaneous vessels. The preparations of mercury, sulphur, garlic, onions, &c. have been detected in the cutaneous exhalation of persons who have swallowed these substances, and hence when they give rise to diaphoresis it has been presumed that they operate by entering the blood-vessels, and stimulating the cutaneous vessels by contact; the specific action of these substances on the skin is, however, very doubtful. The older writers explained the occasional beneficial effects of sudorifics by supposing that some peculiar morbific matter was expelled from the system, the retention of which had produced the disease. Hence such remedies were reckoned among the *Alexipharmaca* and *Alexiteria*. This hypothesis is totally devoid of foundation. Cold may suddenly check the vital action of the skin, and some internal organ may in consequence become disordered; but we ought rather to say that the affection of the internal organ is caused by a metastasis of the vital action, than by a metastasis of the sweat; for although cold diminishes the vital action of the skin (transudation,) yet it does not prevent the physical action (evaporation.) The operation of diaphoretics is facilitated by increasing the quantity of fluids in the system, which is best done by the exhibition of tepid water. They are most likely to be successful if given at bed-time, inasmuch as there appears to be a greater disposition to sweating during sleep (especially towards the morning) than in the waking state. The combination of diuretics or of purgatives with diaphoretics, always diminishes the effect of the latter. If warm liquids be taken into the stomach and cold be applied to the skin, the vital action of transpiration (transudation) will be checked, and diuresis produced.

Class VII. *Errhines.*—Errhines are local irritants applied to the mucous membrane of the nose to excite an increased discharge

of mucus, or to provoke sneezing: in the latter case they are termed *ptarmics* or *sternutatories*. The milder errhines such as sugar, act mechanically: others, for example, asarabacca, veratrum, tobacco, &c. are acrids. They are principally employed as local agents.

Class VIII. *Expectorants.*—Expectorants are medicines which promote the secretion and expulsion of mucus and other secreted matters from the bronchia, the trachea, and the larynx. In the healthy state the mucus secreted by the membrane lining the air passages is got rid of by evaporation and by absorption; but under certain circumstances an accumulation takes place, and nature then endeavours to get rid of it by coughing; the act itself being called expectoration. Hence the term expectorant has sometimes been applied to substances exciting cough, commonly to agents promoting the secretion of bronchial mucus, and sometimes to medicines which diminish bronchial exhalation. For example, Dr. Paris terms sulphate of zinc an expectorant, because in humoral asthma it occasionally moderates exhalation, and consequently renders the expectoration of the mucous secretion more easy.

Some expectorants are *local*, as the vapors of resinous and balsamic substances, dilute chlorine gas, &c.; others are supposed to act through the general system; these may be called *remote* or *indirect* expectorants: among them are the fœtid gums, tobacco, squills, the nauseating emetics, &c.

Class IX. *Emetics.*—Emetics are those medicinal agents used to excite vomiting. All of them produce in the first place more or less unea iness and nausea, the intensity and duration of which, however, bears no relation to the violence and duration of the subsequent vomiting. Thus the sulphates of zinc and copper excite speedy vomiting with but little nausea, and are, therefore, preferred as emetics in narcotic poisoning: tartar emetic, on the contrary, is a powerful nauseant, and is consequently employed when we wish to depress the actions of the system. During the stage of nausea, the pulse is small, feeble, and irregular, the face and lips pale, a sensation of relaxation and coldness of the whole system is experienced, the saliva flows copiously from the mouth, the eyes lose their lustre, and the whole countenance appears dejected. These symptoms continue for a variable period, and are then followed by the ejection of the contents of the stomach. As soon as actual vomiting commences, the general phenomena are altered: the pulse becomes frequent and full, the temperature of the body increases, and a sweat breaks out on the face and other parts of the body. During the act of vomiting, in consequence of the pressure made on the abdominal aorta, and the interuption to the circulation through the lungs, from the impeded respiration, the blood returns with difficulty from the head, the face swells, the conjunctiva becomes turgid and red, the jugular veins are gorged, and the tears burst from the eyes. When the vomiting has entirely ceased the patient feels languid, oppressed, and drowsy, and the pulse becomes weak and slow. The exhaustion is sometimes so great as to be attended with fatal consequences. Dr. Paris mentions a case in which an emetic was imprudently given to a patient in the last stage of phthisis, with the intention of dislodging the pus with which the lungs were embarrassed; syncope was produced, from which the patient never recovered.

The immediate causes of vomiting are numerous, various, and even opposite; but are reducible to three heads:—

1. *Mechanical* agents; as suddenly distending the stomach largely with warm water, or diluents of a similar kind; a practice which we resort to when we wish to excite vomiting with the least possible irritation, and to dilute at the same time. No satisfactory explanation has yet been given of the operation of this cause.

2. *Irritants* applied to the stomach; as undigested food, the acrid and caustic poisons, and the substances usually employed to excite vomiting (emetics); some act simply by the local irritation they produce; for example, mustard, gamboge, euphorbium, &c.; others have in addition, apparently a specific emetic quality, since they excite vomiting to whatever part of the body they be applied: tartar emetic and ipecacuanha are examples of these.

3. *Sympathetic means;* as tickling the throat with the finger or a feather; whirling, sailing, or swinging; certain disagreeable odours; pain; injuries of the brain; calculi in the kidneys, &c. The mode of operation of this class of agents is quite unknown.

Besides the evacuation of the contents of the stomach, emetics produce increased secretion and exhalation from the mucous lining of the stomach and duodenum. When the vomiting has continued for some little time bile is usually evacuated; and it is generally thought that emetics increase the secretion of this fluid as well as of the pancreatic juice.

Class X. *Cathartics.*—Cathartics or purgatives are those medicines which produce alvine evacuations: the mildest are termed laxatives; the strongest drastics; while those that evacuate much water are denominated hydragogues. When we reflect that the intestinal surface consists of

about 1400 square inches, on the whole of which secretion and exhalation is going forward, it must be evident that purging offers a very powerful means of diminishing the quantity of the fluids of the body. Most, if not all, are local irritants, and in some instances the effect seems to depend solely on this, as in the case of gamboge, and of euphorbium. But a considerable number of the drastics appear to have an influence over the bowels independent of their local action, inasmuch as we find them purging though they are applied to the skin, to wounds, or are thrown into the veins. This will occur with castor and croton oils, elaterium, colocynth, hellebore, &c. These are specific purgatives. The substances called laxatives have a very slight local irritant action: indeed, Barbier denies that they are irritants. Some purgatives produce evacuations without the discharge of much liquid matters: these are supposed to act principally on the muscular coat of the intestines. Sulphur, manna, rhubarb, and magnesia, have been enumerated in this list.

All the powerfully irritant purgatives probably increase the secretion of bile by irritating the end of the ductus choledochus; but mercurials, aloes, and rhubarb, are supposed to possess a remarkable power of this kind. Some of the drastics are said to act more on one part of the canal than on others: aloes, black hellebore, elaterium, colocynth, and savine, are supposed to exert a greater action over the large than the small intestines: further experiments and observations, however, are required to confirm this opinion, for the statements usually advanced in proof are not sufficient to establish it. Some purgatives are absorbed: the colouring particles of rhubarb and of gamboge, the odour of oil of turpentine and sulphate of potash, have been detected in the blood; while the colouring matters of cassia pulp, of senna, of rhubarb, and of gamboge, have been detected in the urine: senna, rhubarb, or jalap, given to the nurse, will occasionally render the milk purgative.

Class XI. *Emmenagogues.*—Emmenagogues are substances supposed to have the property of exciting the menstrual discharge. But the uncertainty of all the agents that have been said to possess this power, and the uterus not being an organ intended for the excretion of foreign matters, have led writers to doubt the existence of any agents really possessing a specific emmenagogue effect. When we consider the variety of circumstances that may occasion a suppression of the catamenial discharge, we can have little difficulty in believing that no one substance can prove emmenagogue in all cases. Deficient menstruation is rarely, perhaps, to be considered an idiopathic disease, but merely a symptom of other diseases; and therefore emmenagogues must be relative agents. Most of the medicines which have had this denomination are either stimulants (as the fœtid gums, rue, mercury, &c.) or drastic purgatives (especially those which are supposed to act on the large intestines; as hellebore, savine, and aloes.) Electricity, the warm bath, stimulating injections into the vagina, sexual intercourse, dancing, &c. are amongst the most powerful means of exciting the menstrual discharge, by determining blood towards the pelvis; but unless a disposition to the natural evacuation concurs with the remedies employed, the latter alone seldom succeed. When deficient menstruation seems to depend on, or be connected with, a want of power in the system, the employment of tonies, (as iron and cinchona) is often found beneficial. On the contrary, when the stoppage is accompanied with symptoms of general plethora, blood-letting and other evacuants are the most proper remedies.

Class XII. *Parturientia.* — I think a class should be admitted under this name, to include those agents that assist the parturient efforts of the womb. The ergot of rye may be taken as the type. This class will correspond with the *Abortiva* of Eberle.

Class XIII. *Diuretics.*—Diuretics are substances which are supposed to promote the secretion of urine. Now there are two ways of increasing this secretion: one is by augmenting the quantity of fluids taken into the stomach, or by removing any cause which diminishes the secretion; the second is direct, by means which are supposed to act specifically on the kidneys: the latter are the diuretics properly so called; but they are so exceedingly uncertain in their operation that their existence has been doubted. In fact, this secretion is liable to great variation under ordinary circumstances, so that it is not always easy to say whether a medicine has proved diuretic or not. Temperature, season, climate, and time of day, are among the circumstances which influence the quantity of urine discharged, which has been enormous sometimes even without the use of diuretics. Dodonæus mentions a man who discharged forty pints a day. Barati notices another case where 3674 pints were evacuated in ninety-four days, being at the rate of thirty-nine pints a day for the whole term; and Fonseca knew an instance where 200 pints were evacuated daily, but the time is not mentioned.

The following tables, drawn up by Mr. William Alexander, are to a certain extent useful, in shewing the effect of different diuretics:—

A TABLE *of the different quantities of urine always discharged in an equal time, viz. from nine o'clock in the morning till two o'clock in the afternoon; when an equal quantity of the same liquid was drunk, but with different diuretics, in different quantities, dissolved in it.*

You must, however, recollect that diuretics are relative agents, and their effects are not necessarily the same in the healthy and diseased conditions of the body.

In order to promote diuresis, diluents should be given, and the skin kept cool. If the latter caution be not attended to, the substances exhibited as diuretics frequently become sudorifics. Going into the cold air out of a warm room, or applying cold to the extremities, will oftentimes excite the action of the urinary organs, when all other means have failed: and in hot countries, where the heat provokes excessive sweating, the secretion of urine is very considerably diminished.

Class XIV. *Aphrodisiacs* — These are substances supposed to have the power of exciting the sexual feelings. Phosphorus and cantharides are usually regarded as such.

Class XV. *Sialogogues.* — Sialogogues, or those medicines that excite the salivary discharge, next deserve a few words of explanation. Some of them are *local;* that is, they produce this effect by application to the mouth; and when used in a soft or solid state are termed *masticatories:* of course they act equally on the mucous follicles of the mouth, and on the salivary glands. Some of these agents act mechanically, as when wax or mastic is chewed; others are powerful acrids; for example, ginger, horse-radish, the root of pellitory of Spain, &c. Certain substances, however, act as sialogogues, when applied to distant parts of the body; these are the *remote* sialogogues. Among these may be mentioned the preparations of mercury and of gold, fox-glove, hydrocyanic, arsenious, and nitric acids, nauseants, &c. All of them, however, are more or less inconstant, but the preparations of mercury the least so.

When we excite ptyalism by mercury, it is rather with the view of proving that the system is under its influence, than for any advantage supposed to be derived from an increased flow of saliva.

Class XVI. *Caustics.*—There are three classes of substances which are denominated caustics; namely, heat, or the *actual cautery;* secondly, *escharotics* or *corrosives*, or those that have a powerfully chemical action on the tissues to which they are applied, (as the potassa fusa); and thirdly, *catheretics*, or those that influence the living properties of the part, but have little chemical action, (as the sulphate of copper.) Some caustics have only a local action, others are capable of affecting remote parts. The mineral acids, the alkalies, nitrate of silver, muriate of antimony, and burnt alum, are examples of the first, and the peroxide of mercury and white arsenic of the second.

Class XVII. *Inflammantia.*—Substances capable of exciting inflammation in the parts to which they are applied. When employed so as to excite redness of the skin merely, they are called *Rubefacients.* The milder ones, such as frictions and warm pediluvia, excite the skin temporarily, while the stronger ones, (mustard, for example), irritate and inflame. Where a large ex-

tent of the cutaneous surface has been reddened by one of this class, a febrile condition of the body is set up, as is shewn by the acceleration of the pulse, and increased temperature of the body. Some inflammants occasion vesication, or the exhalation of a thin serous fluid, by which the cuticle is detached from the true skin: these are called *vesicants* or *epispastics.* When a large portion of the skin is separated, we call it a bleb, bulla, or ampulla: but when the detached portion is small and orbicular, a vesicle. Sometimes the inflammantia produce a secretion of pus; they are then called *suppurants.*

Class XVIII. *Acids.*—Acids are used in medicine for a variety of purposes, but I shall notice them here principally as chemical agents acidifying the fluids of the body. When from any cause, such as disordered digestion, particular kinds of foods, or other circumstances, white sand (either phosphate of lime, or phosphate of ammonia and magnesia) appears in the urine, the internal use of acids will frequently diminish or remove it. We likewise resort to the use of acids to neutralize the alkalies, when they have been accidentally or purposely swallowed.

Class XIX. *Alkalies.*—These agents are used to alkalize the contents either of the stomach or the urine. When employed to neutralize any acid which may be found in the stomach, they are termed antacids or absorbents. If the urine contains uric acid, as shewn by the deposition of this substance in the form of red sand or gravel, the alkalies are exceedingly useful in counteracting it.

[It may be proper to state, that this lecture is an abstract of five discourses given in the theatre.]

DR. ELLIOTSON ON LIFE AND MIND*.

To the Editor of the Medical Gazette.

Sir,

In perusing, several years ago, the fourth edition of Dr. Elliotson's translation of Blumenbach's Physiology, I amused myself with making a few notes in the margins of the pages, on some of the accomplished translator's opinions on Life and Mind—opinions which appeared to me to be unworthy of their author, and calculated to bewilder and mislead his readers, particularly the juvenile portion. As part the first of a new treatise on Physiology, by Dr. Elliotson, has just appeared, not so much a translation of Blumenbach as an original work, I was induced, for the purpose of comparison, again to peruse both my own notes and the chapter on life and mind, as it stands in this, the fifth edition; not altogether without the expectation, I confess, of finding the work purged of certain speculative views, which, to say the least of them, are but little fitted for an elementary treatise. In this expectation I was disappointed. The same opinions are stated afresh, with, if possible, greater confidence than before, and illustrated from a variety of sources—from the writings of Gall, from those of several eminent divines, not omitting appeals to the sacred scriptures.

I am far from intending to insinuate that there is any novelty in the opinions referred to. Life and mind have always supplied *quæstiones vexatæ.* They have afforded matter of controversy almost ever since men were accustomed to differ, which is equal to saying, ever since they began to speculate. Very probably such disputes might long ago have been set at rest, had philosophers submitted to confine their attention to the phenomena of animal being, discoverable by consciousness and by observation, and reasoned from these with the same caution they have exhibited in reasoning on most other subjects. But prejudices, chiefly connected with theology, have interfered; and wonderful has been the confusion of thought and language displayed in this above all other controversies, as the reader will readily admit who has the patience to peruse, among a long catalogue of treatises that might be named, the singular work of Barclay on Life and Organization; or the far more interesting, though prolix, chapters on the same subject, in the Memoir of Cullen, by Dr. Thomson.

In his preface the author has intimated that the correction of any errors, and the communication of any facts, either publicly or privately, will be esteemed by him a valuable favour. It is in the same fair and candid spirit, I trust, in which this invitation is given, that I accept it; with the intention, nevertheless, of freely canvassing some of his views, which I cannot help regarding as altogether illogical, and well worthy of refutation for the student's sake, who is but too generally an easy convert to whatever wears the semblance of novelty, provided it is presented with a bold assurance, which dissipates at once all difficulties and doubts.

Much that Dr. Elliotson has written on

---

* Human Physiology, by Dr. Elliotson. Part First. London, 1835.

This letter, and the one which is to follow, were partly prepared for the press last spring, soon after the work appeared; but circumstances, which it is needless to explain, prevented their being earlier forwarded for publication.

life is judicious and philosophical. "We see matter," he observes, "in a certain state, possessed of a certain power which we term life; and the object of physiology is merely to observe its effects, just as it is the object of chemistry to observe the circumstances of the affinity of different bodies, and of physics to observe other phenomena of matter, without vainly speculating on the essence of matter, or the essence of affinity, to comprehend which our faculties are in their nature incompetent*." After sentiments so sound and so well expressed as these, it excites surprise to be told that "the Almighty has endowed organic matter with the superaddition of life†." And the surprise is not lessened when we further read, that "a power or property of matter [*e. g.* life or attraction] cannot be matter‡." The tenableness of the latter opinion I shall have occasion by and by to canvass; but the former, that life is a superaddition to matter, deserves a brief examination, especially as the same view, with respect to the superaddition of certain other qualities to matter, is expressed in another passage in the following terms:—

"Substances consist of particles endowed with certain properties, without which their existence cannot be conceived—viz. extension and impenetrability, with others which proceed, indeed, from their existence, but are capable of being subdued by opposing energies, namely, mobility, inertness, and with others apparently neither necessary to their existence, nor flowing from it, but merely superadded; for example, various attractions and repulsions, and various powers of affecting animated systems§."

This account of matter is far from being unexceptionable, for several reasons, but I shall refer to one only. It is no doubt allowable to say, with reference to extension and impenetrability, that, constituted as our senses are, these qualities necessarily enter into our conception of matter, as something extended and capable of resisting compression; and with regard to certain other qualities of matter, that they are unnecessary to this abstract conception of it. But instead of this guarded view, the writer expresses himself in such a manner as to imply that there are certain qualities necessary to the existence of matter, and certain other qualities which neither flow from, nor are necessary to, that existence, but merely superadded; which seems to me to be altogether erroneous; and, moreover, as we shall see, is the source of confusion in some of his subsequent reasoning. It has been customary for metaphysicians to divide the qualities of matter into two classes, primary and secondary, in order to distinguish such as matter in every form exhibits, and which consequently are essential to *a definition* of it, from such as it may or may not exhibit, according to specific differences existing between different substances, and according as any given substance undergoes changes in its chemical or its mechanical states. But why should it be thought that the one class of qualities is essential to the existence of the particles of substances, and the other not? Why are extension and impenetrability qualities more essential to the existence of the particles of the substance named gold, for example, than yellowness, which, according to Dr. Elliotson, is a superadded quality? Matter, in every condition it is possible to conceive of it, we are never to forget is only known to us by certain qualities, and that by a quality of matter, whether it be a primary or a secondary quality, we mean *that* which is the cause of a particular sensation in us percipient beings, and mean nothing more. Extension and impenetrability, therefore, are nothing but matter *in certain relations to the mind*, precisely as mobility, attraction, inertness, colour, viscidity, fluidity, odour, sweetness, are nothing but matter in certain other relations to the mind. The feelings of extension, colour, sweetness, &c., it is true, are not matter, but feelings excited by matter, accompanied *necessarily* by the belief, however, that matter when it excites such feelings is extended, coloured, sweet. Hence it is clear that yellowness—that quality of the particles of the substance gold which excites in me a feeling of yellowness—is not something superadded to the gold. On the contrary, it is doubtless as essential to the existence of the gold, in the circumstances in which this quality is perceived by me, as extension and impenetrability are to the existence of matter in general. To assert that yellowness is not necessary to the existence of the gold, in the circumstances in which this quality is perceived by me, is to assert what is utterly unmeaning; for what, I ask, is the yellowness of the gold, but the gold itself in a certain relation to the percipient mind? just as the quality of impenetrability, likewise possessed by the gold, is nothing else than the gold in a certain different relation to the same percipient mind*.

To apply these observations to the phe-

* Page 30. ‡ Page 39.
† Page 41. § Page 2.

* It is scarcely needful to remind the young student that "matter in the abstract," or "matter in general," is nothing in nature, but is merely a logical figment. Matter which is known to us, that is to say terrestrial matter, is gold, silver, sulphur, phosphorus, or one of the other uncompounded bodies; or a compound of two or more of these.

nomena of life:—"The Almighty," says the writer, "has endowed organic matter with the superaddition of life." Here, then, is a further addition to organic matter, besides the qualities previously superadded before it was organized: in other words, living organic matter possesses, first, qualities necessary to its existence as matter; secondly, qualities not necessary, but superadded; and, thirdly, vital qualities superadded to both! This statement, in my opinion, is perfectly erroneous. It is enough if we say that what are called the phenomena of life are qualities of matter in certain conditions, necessarily arising, so far as we know, from such conditions. Life, indeed, is not the name of a quality, properly speaking, but a generic term inclusive of a great number of qualities, which matter, as it exists in animals and vegetables, impresses on the percipient mind; these vital qualities, to vary the mode of expression, being *nothing else* than matter, as it exists in such bodies, perceived by the mind through the instrumentality of the senses. So far from having reason to regard the phenomena of life as qualities superadded to organic matter, we have no reason whatever to infer that matter could exist, in the *identical state* in which it exists as a plant or an animal, without exhibiting the identical vital phenomena it does exhibit, any more than we have to infer that oxygen could exist as oxygen, without possessing its present properties; or matter in general exist without possessing extension. Were I to be shown a mass of iron, or of granite, exhibiting vital phenomena, I should be ready to admit that life was, in this instance, superadded, knowing that iron and granite do not commonly exhibit such qualities; but when I see vital properties always belonging to matter, in forms, as regards their composition, perfectly unique, and which art cannot imitate, I infer that they are the properties of matter in such an inimitably compounded condition; and the conclusion is warranted by the fairest analogy, it being found that changes in the composition and mechanical condition of matter, are attended by corresponding changes of properties. A lump of gypsum, for example, possesses certain properties. We separate its constituents, and a variety of new properties are immediately exhibited. We reunite the substances; the new properties vanish, and the old properties return. Here it is surely reasonable to infer that the changes, in regard to properties, resulted from changes in the conditions of the matter. If it should be said that the conclusion is a precarious one, because there is little or no analogy between chemical and vital properties, I reply that as little analogy is there between the condition of a chemical salt and that of a seed or an ovum. If the two classes of properties are immensely different, no less wonderfully different are the two kinds of bodies as to the nature of their composition. I wave, however, all further remarks on Dr. Elliotson's opinions concerning life, as my own views on that subject are to be found, in a very brief form, in an early volume of the Medical Gazette, in refutation of an hypothesis by Dr. Prout*, and in what remains I shall confine myself to the author's sentiments on mind.

"Mind," says Dr. Elliotson, "is the functional power of the living brain. As I cannot conceive life, any more than the power of attraction, unless possessed by matter, so I cannot conceive mind unless possessed by a brain, or by some nervous organ, whatever name we may choose to give it, endowed with life. I speak of terrestrial, or animal mind; with angelic and divine nature we have nothing to do; and of them we know, in the same respects, nothing†." Again, "A physical inquirer has to do with only what he observes: he finds this power, but attempts not to explain it. He simply says the living brain has this power, medullary matter though it be. Seeing that the brain thinks, and feels, and wills, as *clearly* as that the liver has the power of producing bile, and does produce it, and a salt the power of producing a certain form, and does crystallize, he leaves others at liberty to fancy an hypothesis of its being a subtle, immaterial, immortal substance‡."

These passages sufficiently convey the writer's opinion, that it is the brain which feels, thinks, and wills; or, in other words, that what are called the qualities of the mind, are, properly speaking, qualities of the brain,—the brain and the mind, so far as these phenomena are concerned, being identical. The arguments by which he strives to support this view will be examined in a future letter. Were it, however, a *sine qua non*, dissenting as I do from Dr. E., that I must of necessity maintain by argument that the mind is immortal—the shift, in part, which he assumes an opponent must be forced upon—I should decline the discussion. Whether I hold the mind to be an immortal substance, or the contrary, has nothing to do with the proposition in question, which is limited to this, that *the brain thinks, as clearly as that the liver secretes bile*. It will appear, I trust, in what I shall say, that I am at liberty to steer clear of all hypotheses whatever relative to the mind's destiny, and that I am

* Lond. Med. Gaz. vol. viii. p. 144.
† Part I. page 32.
‡ Ibid. I. page 39.

in no instance obliged to advance beyond what I actually know from simple consciousness, and consciousness aided by the senses.

When a person is led to reflect on the knowledge he possesses,—suppose of mind, of a chemical salt, of the medullary substance brain, of the bile, or of other objects,—and sets himself to discover how he obtains his knowledge, he finds that the inquiry is exceedingly simple. He speedily dicovers that, leaving testimony out of the account, his knowledge of mind is derived from consciousness, and that from no other source does he obtain his knowledge of it. He is conscious that he exists—that he has feeling, reason, and volition — and that these faculties, which, by turning the mind to contemplate its own operations, he is able to subject to rigid examination, belong to *that*, whatever it is, which he is accustomed to denominate *I*. Further, by a law of his nature, he is conscious that his hand, his foot, the other parts of his body, and all objects which impress his senses, are distinct from this same entity. He never confounds this conscious being with any thing else whatever, and intuitively feels that it involves an absurdity to suppose that it could be added to, or subtracted from, or divided. In a crowd, in solitude, at all times, and however occupied, he never doubts of his own identity —that he is in every respect the same being to-day that he was yesterday. The properties of mind he learns by consciousness, and by a law of his nature is compelled to ascribe them to *something* of which they are the properties. The properties of matter he obtains a knowledge of also by consciousness, through the aid of the senses, and intuitively refers them to *something else*, of which they are the properties. Concerning matter equally as concerning mind, all his knowledge depends on consciousness, in the more extended sense of that word. And yet, as has been stated, by a law of his being, he never confounds perceptions of mental properties—volition, reason, memory, fear, hope, joy—with perceptions arising from impressions made on the senses—extension, hardness, fluidity, bitterness; in other words, he never confounds the properties of mind with those of matter, nor ceases to feel, whenever he reflects on the subject, that matter in all its forms is one thing, and mind, in all its infinitely diversified states, is another and entirely different thing.

These are first principles (if I, indeed, have succeeded in stating them correctly), which it is not optional to admit or to reject. If they are rejected, every proposition which it is possible to present for the assent of a rational being may be rejected. On the assumption, then, that they are indubitably true, I proceed to the examination of this notable proposition,—that it is as clear that the brain thinks, as that it is the liver which secretes bile. In regard to the liver, I become acquainted with it by the help of my senses; as also, by the same means, with the fact that the bile is formed in the liver, and issues from its duct. No sane person will differ from me on this point: he will at once assent that it is the liver which produces the bile. In like manner, were I to subject a liquefied salt to the action of heat, he would agree with me, on witnessing the formation of crystals, that the saline particles have the power of taking a certain definite crystalline form. In these instances I should need to assume nothing; what I asserted would be granted without a moment's hesitation. But Dr. E. asserts that it is not more clear that the liver produces the bile, than that it is the brain which feels, thinks, and wills. Will this, I ask, be as readily conceded as true? Manifestly not. *I*, for one, do not acknowledge that there is sufficient resemblance between mind and bile—between secretion and thinking—to warrant the comparison at all; or that the knowledge we possess of the one class of phenomena can be employed for the elucidation, in the way of analogy, of the other class; and that *I* am altogether *singular* in thus dissenting from this opinion of the writer, no one will assert. The bile is obviously matter, the crystal is matter, and both are confessedly products of matter; in short, matter in fresh forms. But thought, volition, anger, joy—the alleged products of the brain—are not *obviously* matter in fresh forms. Has Dr. Elliotson touched a volition? Has he tasted or smelt an emotion? When has he weighed or measured a thought, confined it in a jar, reflected or refracted it, or made it inhere in some body, so as to demonstrate its presence and its nature? Has he examined its qualities by a chemical test? If he has done none of these things, it is evident that mind does not possess the properties of matter, according to any known definition of that substance. And if it cannot be shewn that mind possesses so much as one quality either of ponderable or imponderable matter, how can it be with fairness affirmed that mind is a product of the brain, as clearly as that bile is a product of the liver? It may be suggested, further, whether it at all diminishes the difficulty, to assert, with Dr. E., that mind is *a property* of the living brain, since a property of matter, be it living or brute matter, is nothing different, and *cannot be conceived as any thing different*, from matter.

That Dr. Elliotson has fallen into some confusion of thought, appears from this

avowal—that as he cannot conceive life more than the power of attraction, unless possessed by matter, no more can he conceive mind, unless possessed by a brain; which is tantamount to saying that he sees no more difficulty in conceiving the brain to exhibit the phenomena of mind, than in conceiving matter to exhibit the phenomena of life and attraction. But here he falls into the error of comparing mere terms—life and attraction being nothing else than terms which express certain phenomena of matter—with mind, which it is a gratuitous assumption on his part to represent as a term expressive of phenomena of matter. The comparison, therefore, cannot be allowed.

Another proof of confusion of thought appears in the singular assertion, that he cannot *conceive* mind unless possessed by a brain. For my part, I could conceive mind, were I entirely ignorant of animal anatomy. A brain enters in no respect into my conception of mind. The intimate and wonderful connexion that subsists in animals between a brain and mind, is a fact in physical science which might have remained unknown as late in the progress of discovery as the circulation of the blood, or even to the present hour, without, perhaps, materially retarding the progress of mental science. That the idea of a brain, then, is *necessary*, in order to conceive of mind, is not to be admitted. The idea of a brain does not enter, I venture to assert, into Dr. E.'s conception of mind. His meaning must be, that he has no knowledge of the existence of any terrestrial mind, *his own conscious mind excepted*, except as exhibited in a living animal; in other words, that he knows nothing of *disembodied* mind. And no wonder, unless it were thought reasonable that minds should be visible, and might be subjected to examination, as the naturalist examines his specimens of moths and plants.

It is true we have irresistible evidence for the existence of other minds besides our own. Every person intuitively assents to the irresistible nature of the evidence for this fact. What I consciously experience in myself, however, with respect to the nature and power of my own mental faculties, is to me the *sole basis* of this evidence. I reason, and I perform a variety of operations, using means to an end. In the mechanism and actions of my own body, and in all nature around me, I behold proofs of agency and design, although the agent I discover not: nevertheless, when once I have detected, not contrivance alone, but wonderful skill, employed in effecting an infinite variety of designs, I intuitively infer the existence of an intelligent mind, the author or cause of all such effects. This is an intuitive, irresistible inference. I have no conscious perception of the supreme mind, nor of inferior minds, distinct from my own. I infer the existence of the Deity from his works, in the same manner precisely as I infer the existence of a fellow mind; it being in the nature of things impossible, without miraculous aid, that I should form even the faintest conception of the existence and attributes of other minds, except by the evidence of such operations on matter as I am conscious that my own mind is, in some degree, capable of imitating or producing: which is merely a different mode of affirming that the existence of no mind can become known to me unless it is possessed of faculties in some sense resembling those of my own. Doubtless the evidence for the existence of a fellow-mind is more clearly and immediately perceived than that for the existence of the Deity, because the evidence for the former is of easier observation, and lies within an infinitely smaller compass. I behold a form and organs, like my own, moving and acting with intelligence, as I myself move and act; and to this form I intuitively ascribe the possession of a mind with like faculties and affections. In this *inferential* recognition of a fellow-mind, what need is there I should recollect, or even know, that there is a brain and nerves, by which it in some manner operates, more than that there is, in the same body, the pancreas and the pineal gland?

A question sometimes started by those who regard the brain and the mind as identical, is this: if it be not the brain's office to think, of what use is so large an organ in the animal economy? The brain, it may be said in reply, probably, indeed certainly, serves a *variety* of uses in the animal economy *. But the question is a mere trap, and there is no need whatever to be entangled in it; for they who assert that the brain is the mind, are bound to prove what they affirm, and not to throw the burden of proving what are the uses of the brain on their opponents. In reflecting on what this question imports, the student is especially bound to recollect and consider well what mind is—that it is an existence having no quality in common with anything in the material world; that it is by mind alone he investigates the structure and the functions of the brain—the nature of the mind itself, the nature of whatever besides he attends to; and that without mind he could know nothing—could not even so much as doubt whether or not he possesses a mind! Should he disregard this preliminary train of reflection, he will in all probability feel the

* See the Gulstonian Lectures and the other Physiological Works of Dr. A. P. W. Philip.

question to be very perplexing, since he will be ready to regard the mind in the same light as the materialist—as being not that most wonderful thing that thinks, but something that is analogous to the parts and products of the body,—a mistake which will leave him deservedly in the power of his assailant. Unhappily, the ability to turn the mind inwards, to study its own qualities, is apt to be in a great measure lost, or, perhaps, never acquired, for want of cultivating, in a moderate degree, the habit of abstraction; and thus the power of accurate discriminative thought is greatly impaired, or altogether wanting. If the student possess and have diligently exercised the power of reflecting on his own mental operations, he will perceive that *primâ facie* he ought not to admit that the brain is the mind, without the clearest and most direct evidence; for this weighty reason—that he knew a great deal about the mind, had been intimately acquainted with its powers and properties, when as yet he knew little or nothing respecting the brain. While, therefore, he recognizes the *uses* of the brain and nerves, as a legitimate and interesting object of physiological inquiry, he clearly perceives that, merely for the purpose of extricating himself from the dilemma his opponent is attempting to force him into, it is one he is no ways particularly concerned to pursue.

Were it my present object to discuss what are the uses of the brain in the animal body, I should have no objection, with Dr. Elliotson, to allowing that the brain, besides other purposes which it subserves, is the organ of the mind; provided we agreed to attach to the term *organ*, in this relation, a modified meaning. This proviso would be necessary; for if we say that the brain is the organ of mind, and the lachrymal gland is the organ of tears, attaching the same meaning to the term organ in these different connexions, we fall into palpable error; and why?—because while it is matter of fact—a thing not admitting of dispute—that the use or function of the lachrymal gland is to separate from the blood the tears, we are not warranted in affirming of the brain that its indisputable use or function is to separate from the blood, mind—to produce, in any way, mind from matter, or even at all to *produce* or *originate* mind: consequently the brain is the organ of the mind in a manner, and *in a sense*, totally different from that in which the lachrymal gland is the organ of the tears.

Let us briefly inquire (ought I not rather to say conjecture?) in what respects the brain and nerves are to be regarded as instrumental in the operations of the mind. The nerves appear to be instrumental in sensation, in the widest sense of that term; visible objects the mind perceives by the instrumentality of the optic nerves, odours by the olfactory nerves, sounds and sapid bodies by the nerves appropriated to the senses of hearing and taste; and touch, heat, cold, muscular conditions, a great variety of sensations in the stomach and alimentary canal, and in the other systems of organs in sickness and in health, by means of nerves and of certain prolongations of the spinal marrow, extending within the cranium. Unquestionably the phenomena of sensation in the animal kingdom, with perhaps a few exceptions, is co-extensive with the endowment of nerves; and defect in the sentient power is found to accompany a morbid state of the nervous structure. It is likewise no less true that volition, in producing the infinite variety of muscular motion, acts by certain portions of the spinal marrow and certain nerves which exist for this special office. The brain, indeed, we are taught to believe, according to the most recent discoveries (if, indeed, the deductions of vivisectors are, in the present state of our knowledge, really entitled to the name of discoveries), is necessary "not so much that the mind may feel impressions, as that they may be remembered and availed of for useful purposes; not so much that volitions may act as stimuli on muscles, as that acts of volition may be so excited as to produce regular and voluntary actions under the guidance of desires, and of judgment and experience, as distinguished from blind instinct *."

Thus the brain, it should seem, is the centre where, by the instrumentality of nerves of sense and of portions of the spinal cord, the mind receives all manner of impressions of bodily conditions, and of objects without; as likewise the centre whence, by the instrumentality of a different set of nervous prolongations, it moves the muscles in using the hands, in walking, standing, running, leaping; in the motions of the eyes, in eating, in speaking, and in thousands of minor acts which are continually being performed, and are too numerous even to be recounted.

Seeing, then, the mind obtains its knowledge of facts relative to the external world, by the instrumentality of the nervous substance, is there not reason to infer that in *conception, memory, recollection*—*i. e.* in retaining present perceptions and in recalling such as are past—*the mind employs the same kind of nervous instrumentality as that by which it in the first instance obtains them?* A large number of facts seem to warrant an affirmative answer; for it is well known that confused perception, and

* See Dr. Allison's View of the Progress of Medical Science in the present Century.

partial as well as complete losses of memory, are frequent consequences of diseases affecting the brain; as likewise, in some degree, of that induration of the brain which occurs in extreme old age. I remember conversing with a gentleman, who, having had a severe attack of fever five or six years before, still remained in entire oblivion of all the events of his life previous to his illness. He was a widower at the period of the seizure, but he had no recollection of his wife. In one instance only did he imagine that he obtained a glance of the past. On paying a visit to the house where he resided before and at the time the fever took him, he entered one of the apartments, and instantly felt a persuasion that he had been there before. Whether or not perfect recollection has in this instance returned, I am unable to say. Some persons, again, after an illness or an accident affecting the brain, have forgotten, for a time, the language they were in the habit of speaking, and commenced speaking a language they formerly learned, but had apparently ceased to remember. Others have forgotten the names of certain objects, or the names of certain classes of objects. The variety of affections of this nature is, indeed, very great. The student will find an account of them, written with much discrimination, in Abercrombie's Inquiries concerning the Intellectual Powers; a work chiefly designed for students of medicine, and worthy of their most attentive study. In old age, when the brain loses that softness which is probably the necessary condition of fitness for the perfect exercise of memory; perception and memory, and, as a consequence, attention, are the faculties which become defective; the mind acquiring with great difficulty fresh knowledge, and, with no less difficulty, recalling the old. Hence ensues inactivity of mind, which being accompanied by a feeling of diminished muscular vigour, of general infirmity, of diminished power to impart or to receive pleasure, ends but too often in the melancholy spectacle of habitual discontent; the judgment and certain classes of the emotions still remaining *unimpaired*. Were this line of inquiry to be pursued as far as it might, perhaps, fairly be, it would, I think, be made to appear that delirium and coma, and a large proportion of mental diseases, admit of being traced to modifications of disordered perception and memory; and, as a consequence, to some species of morbid affection of the nervous substance instrumental in the production of these mental states.

Admitting that this view of the instrumentality of the nervous substance is worthy of regard (as I apprehend it is), if we reflect how incessantly the mind is receiving an infinity of impressions from the world around, by means of the senses alone, and new ideas by reflection, aided by the senses—ideas also from testimony in reading and in conversing, and ideas in reverie and dreaming—the number of orders it is ceaselessly sending through the nerves to the motive organs; and the almost as ceaseless demands it is making on the brain for the reproduction of perceptions, in musing, in deliberate reflection, in public speaking, in conversation, in the different kinds of literary composition, in the transaction of business, and in practising the useful and elegant arts—perceptions which are numberless as the sands on the sea shore—we discover that the brain is exceedingly well employed, even were it a larger organ than it is; in fact, that if the brain perform merely the work which has now been assigned to it, it must be allowed to be, beyond comparison, the busiest and best employed organ in the body, without its needing to have imposed upon it the additional exercises of volition, judgment, imagination, emotion; none of which, as mental states, are, so far as is known, manifested by the instrumentality of organic processes *.

Should it, however, ultimately appear to be established on the basis of physiological experiment, that every manifestation of mind, without exception, is accompanied by an organic process, this would be insufficient to secure general assent to the author's proposition, that it is the brain which thinks. An intuitive truth does not lie at the mercy of an experiment. At the present time it is a fact universally admitted that the mental state we call *sensation*, is, in every instance, accompanied by an organic process; and yet few, I presume, bring themselves to believe that it is the nervous organ that feels. Who has ever brought himself really to believe, because the optic nerve is the instrument in seeing, that it is the optic nerve which sees? The impossibility of believing (to say nothing of *proving*) that the mind, which feels and recollects by the instrumentality of the nervous substance, is itself the same identical nervous substance, admits of easy and convincing illustration. I will mention one example. At night, after long-continued and extreme fatigue, I find it to be my duty to examine and rectify an entangled account which has relation to a great number of intricate, extensive transactions, of different dates. On making the attempt, I find myself un-

* It affords me much pleasure to refer the reader to Prichard on the Vital Principle—a work containing many views, however, which I cannot assent to—for much lucid discussion on the instrumentality of the nervous system in the operations of the mind.

equal to the task: the power of attention is wanting. I endeavour to recal a variety of perceptions which are necessary in the commencement of my labour, but in vain; my thoughts do not flow in the usual trains, and every effort at recollection recals only confused masses of perceptions, which disperse, and are succeeded by others equally confused. The duty is not imperative; I might, if I chose, postpone it till another time, but I say to myself, "No; I am determined the account shall be rectified before I sleep; I will not give way to lassitude." I hereupon rise, walk briskly about, and *resolve* that I will not be foiled. What happens? I conquer. The mind regains the mastery. It compels the wearied brain and other organs to obey, and once more exercises its powers in conscious triumph. Would it be rational to say, in this instance, that the mind, which triumphs over the lassitude of the nervous organ enforcing obedience, is merely that organ triumphing over itself? —the living brain compelling the obedience of the same living brain?

In conclusion, then, to assert that it is *obviously* the brain which thinks, is unphilosophical; because it is to trifle with the nature of evidence, the assertion being incapable of proof by any known method of observation and reasoning. Perhaps it may be said, that if it cannot be actually proved that it is the brain which thinks, it may be shewn to be probable. To this notion it is sufficient to reply, that it will require a wonderful amount of proof, and that the proofs be marshalled in some perfectly novel manner, to render it even in the lowest degree probable; because the fact assumed is, as we have seen, altogether repugnant to the natural principles of belief. Before I can admit, therefore, that the living brain is the mind, I must be prepared to believe that what I, and every one else, intuitively reject, may notwithstanding be true: in a word, that the fundamental laws of human belief are of less authority than a disputed inference in the unsettled and, as yet, unsatisfactory science of animal physiology.

But a thousand facts demonstrate, as I have fully admitted, the intimate connexion which subsists between the mind and the brain; the dependence of the mind, in order to the exercise of its faculties, on the integrity, in general, of that organ; and that certain conditions of the nervous system, springing from age, race, education, and the like, are attended by corresponding modifications of mind. These, and other arguments of Dr. Elliotson, in favour of what I presume to call his hypothesis of the mind's materiality, remain for examination in a future letter: not that I admit that any such hypothesis is wanted, or that it is other than gratuitous. It can serve no scientific end; it maintains an unavailing struggle with the unalterable, because intuitive, laws of human belief. Nevertheless, as the hypothesis in question admits of being stated and recommended with some show of plausibility, it is on that account entitled to examination.

Yours respectfully,
JOHN ROBERTON.

Manchester, Nov. 7, 1835.

PRACTICAL SUGGESTIONS

INVITED FOR THE

IMPROVEMENT OF THE NEXT CENSUS.

To the Editor of the Medical Gazette.

SIR,

As you have deemed some of the results of our English population inquiries to be proper for admission into your pages, you may not, perhaps, see any objection to the insertion of observations defensive, at least explanatory, of the process hitherto pursued, and thereby leading the attention of the public towards the suggestion of improvements in the year 1841, or rather in the Act of Parliament in the preceding year, under which the census will be repeated. For although the public, and parish authorities especially, have shewn themselves favourable beyond expectation to these inquiries, and the thinking portion of mankind have not been dissatisfied with the manner in which the results have been exhibited for ready use, they cannot but labour under some disadvantages in speculating on further improvements, because they cannot combine the knowledge of negative as well as of positive arguments; or, in one word, they have not the benefit of experience as a basis for projected improvements; and if I am able to supply that defect in any reasonable degree, I shall not have written this letter in vain.

The first element of the inquiry, the enumeration of the people, has not obtained so much credit as justly belongs to it,—and this, because the mode of pursuing the inquiry appears too simple and vulgar for insuring precision,—because public functionaries are not formally appointed for enforcing attention to the task,—because a law, with little appearance of stringency, is therefore

supposed to be ineffectual. But as far as I have been a spectator of legislation, I should argue conversely, that the more apparatus (necessary or unnecessary) appears in any law, the less likely is it to arrive at a satisfactory result.

I do not suppose that any defect is suspected in the enumeration of the higher—the more conspicuous, classes of society; and those objectors who are not familiar with the operation of the English Poor Laws (which do not extend to Scotland or Ireland), cannot duly estimate the value of our "overseers of the poor," for the purpose of enumerating the inhabitants of every parish or subordinate district which maintains its own poor. In this, as in the case of members of parliament and other popular functionaries, the law of England usually assigns two persons of joint authority for executing the same duty, so that public business shall not be deranged by the illness or occasional absence of any single person. These overseers of the poor have their attention so often called to the condition, and especially to the number, of every poor man's family in their several districts, that in a small parish the overseer is almost able to enumerate the inhabitants without stirring from his own fireside, and in large or populous parishes, is not without assistants replete with the same kind of local knowledge, and who, for the moderate reward offered by the Population Act, are quite ready to perform the duty required by it. Under these circumstances, I request those who doubt of the accuracy of the English enumeration, to compare the probability of successful inquiry, by means of persons who are habitually compelled, by applications for relief, to be conversant in the affairs of every poor family,—with the probability of success by means of any other persons, however well rewarded, however zealous, but who must first sedulously inquire for every cottage and tenement in a rural district, every cellar and garret in a town, before they can visit every family, and enable themselves to answer the simple questions—how many houses, families, and persons, exist in a limited district?—the very limit, the boundary of which, is unknown to those whose office or employment does not compel them to be familiar with it.

I do not herein seek to derogate from the accuracy of the parochial schoolmasters in Scotland, who, for some reasons not dissimilar from the above, for other reasons different, but advantageous, arising from education, have produced a satisfactory return from the northern part of Great Britain.

I mean to confine myself to the supposed weak part of the population inquiry, and think I have shewn, that unless from intentional error or default, the overseers of the poor in England have always made a full and a true return, to the best of their knowledge and belief, as certified by them upon oath before the local magistracy. The chance of their doing otherwise must be estimated according to the strength of temptation operating upon their minds; and the absence of any such temptation ought to satisfy a candid inquirer that he may safely rely on the enumerations of the years 1801, 1811, 1821, and 1831. A shade of doubt, or rather a want of entire confidence, regarding the first of these enumerations, arose from its being an untried experiment, and from the effect of an Act of Parliament which a few years before had compelled parishes to supply men for the naval service. These doubts were not unreasonably urged, nor entirely withdrawn, until three more enumerations had been completed, when a comparative account of the four results in every parish was published in the beginning of the year 1832. This left little room to impugn the earliest enumeration, and the general consistency of the whole afforded satisfactory evidence to every experienced eye, that good faith had pervaded the entire returns. As to the possibility of official concealment or cookery in digesting the returns, it is negatived by the usual publication of them in the several county newspapers at the time; so that the official compiler could not hope to escape detection if he swerved from the truth in the return of any place, or in the totals of any county.

In the Population Act of 1801, the question as to occupation or employment applied to all persons. No such question (as far as I know), had been asked in any other nation; and the mistake of supposing every individual (females, children, and servants, not excepted), to be distinguishable according to occupation, rendered this question of no avail in 1801, as having been variously understood, or remaining un-

answered, from its obscurity. In the three subsequent enumerations, this question was made to apply to families instead of individuals; and in 1831, all males upwards of twenty years of age (amounting to one-fourth of the entire population), were questioned as to their occupations; which inquiry produced a more complete result than was anticipated.

In the year 1821, an important question was hazarded, as to the age of every individual; classing the ages by five years under the age of twenty, by ten years from thence to 100, and finally a class of centenarians. On this occasion it was to be considered whether peremptory legislation was advisable, or whether the object in view was not likely to be more accurately, as well as more easily attained, by adopting the voluntary principle in this personal investigation. For supposing nine-tenths, or a much less proportion (indifferently taken among the population) to make true answer to this inquiry, its object was answered, because by applying the numbers of the several classes to a radix of 10,000, especially if worked on every county, an answer (not the less satisfactory from being inferential) was given to the various questions of mortality, or of increase of population, which cannot be elucidated otherwise than by a classification of the ages of existing individuals. The question was therefore put as a concluding question, in the following words:—"If you are of opinion that in making the preceding inquiries (or at any time before returning this schedule), the ages of the several individuals can be obtained, in a manner satisfactory to yourself and not inconvenient to them, be pleased to state the number of those who are under five years of age, of those between five and ten years of age, &c., distinguishing males from females?" Long afterwards I met with this question copied into the work of a learned foreigner (M. D'Ivernois), who was much struck by this language of respectful request in a national inquiry, making inferences favourable to the civilization and good order of a nation which could be so gently governed by its legislature. On this occasion, the ages of eight-ninths of the population was obtained; the defect of one-ninth arising from entire parishes where the overseers declined the task.

We Englishmen owe thanks to M. D'Ivernois for his good opinion, which is not altogether unmerited; indeed, I may personally add, that in the many thousand applications which it has been my duty to make, soliciting returns, or the correction of returns, where from negligence or accident any defect has occurred, I have never received an uncivil answer; and the success of the parish register inquiry, as well as the enumeration, proves that finally due compliance was obtained. But, in truth, extorted, or even unwilling obedience, is in some cases worse than disobedience; and answers inserted at random by an overseer who might dislike the task of inquiring ages, would be manifestly of this character, as destroying the accuracy of any proportional radix worked on an otherwise accurate return.

I confess that, on more extensive reasoning and general argument, I much dislike such peremptory legislation as affects every individual in a community, and which, if not completely successful, perpetrates evil instead of conferring benefit; without which no alteration in the conventional arrangements of society is justifiable. To alter by force of law the language of a nation, or any part of a nation, has never yet been accomplished. Experiments of a milder character, such as the alteration of the calendar, or of weights and measures, were tried in the course of the French Revolution, with the advantage of absolute power on the side of the innovators. These laws had been preceded by that of the *maximum* (a regulation of the price of food), and many victims perished under the guillotine for disobedience to this dreadful law, which yet failed of effect. The same legislators attempted alteration in the calendar, whereby a seventh day of rest or enjoyment, was to be superseded by a tenth day; but this law only produced confusion until it was repealed, after ten years' trial.

The uniformity of weights and measures throughout France was highly desirable, and underwent a legislative experiment, whereby the multiples and aliquot parts of a *gramme*, or a *metre*, respectively, were to become universal in the daily transactions of every individual. But philosophy was dangerously mixed with this attempt to produce national convenience. The *gramme* and the *metre* were not recognized by the French public, who were not conciliated

by an attempt to introduce the Greek language into the common transactions of mercantile life*. Had the most usual pound weight, and the well-known French foot and toise, been generalized by law, a strong party would have favoured the innovation, and the new law might have become effectual and highly beneficial. An English law of the same kind, in the year 1826, created a new *bushel* under the old name, but incommensurable with the established corn bushel of the south of England and the metropolis, commonly called the *Winchester* bushel, which last, with such aid, might perhaps have been established as the standard bushel for all purposes. At present we only know that great expense has been incurred, and that all experience and knowledge of the corn trade (no unimportant branch of statistics), whether held in memory, or published in books, has been thrown into confusion, or superseded; and this law, after a vain effort to succeed by persuasion, seems destined to continue the experiment by force of penalties and forfeiture†.

Thus much in notice of laws which war against the habits and previous knowledge of a civilized community. What little of penalty or coercion appears in the Population Acts has not been found necessary in practice; and I must be permitted to estimate the accuracy of information thus obtained as highly as that produced by similar inquiries, which are supposed to be strictly enforced elsewhere. I know that an answer, true or untrue, may be exacted by a severe law; but I estimate the value of such answers inversely according to the threats employed and the penalties enforced.

Having now endeavoured to shield our English enumeration from random imputations of inaccuracy, which even in printed books are sometimes assumed as matter of course, undisputed and indisputable, I proceed to notice the only specific charge which has come to my knowledge impugning the enumeration of 1831, or rather that part of it which endeavoured to distinguish the various employments of the trading and handicraft portion of the community. In the Edinburgh Review of April last, objections are stated in a somewhat ludicrous manner against this attempted discrimination. It is impossible to be displeased at this, especially in a publication which heretofore has bestowed very useful attention on the subject of population and the law of mortality; and I only answer that precise accuracy in such a classification is known to be impracticable; but that a knowledge of the number of many of the classes cannot fail to be serviceable in statistical considerations, and finally, that most of the actions of mankind rely upon data much less accurate; nay, that if all imperfect knowledge had been withheld, or were now banished from the earth, we should find ourselves the most benighted race of animals on its surface; as scarcely any thing but arithmetic and the other branches of the mathematics would be left in our minds, and the experience of five or six thousand years in the common affairs of life must be slighted under such severe examination. Better it were that the reviewer, and others of his acknowledged talents, should bestow their attention on the improvement of the next census, as indeed he recommends, but does not exemplify by any practical detail.

He praises, in the census of 1831, and I venture to think justly, the three distinctions of those who cultivate land; adding, however, "and had those employed in taking the census been placed under efficient check or control, to make sure they did their duty, the answers might be depended on." But the census must be taken, at least commenced, on the same day; when about 30,000 persons (averaged at two in every parish or township) are simultaneously employed in it, making inquiry from house to house. Would he appoint another 30,000 persons, specially to superintend the proceedings of that day?—or would he appoint a less number, to pursue the same process during the next month, assigning several parishes to each of these controllers? The latter expedient is obviously preferable: but who is to appreciate and appoint 1000 persons fit for this task? Not the Secretary of State, because he does not possess universal local knowledge; and the appointment must emanate from the

* For common purposes the *metre* may be deemed to exceed the English yard by one-tenth part.

† The imperial bushel (so it is called) exceeds the ancient Winchester corn bushel by one thirty third more nearly than one thirty-second part; but the last is more convenient for memory, being two gallons, or one peck. The exact difference of the old and new corn bushel runs into a line of decimals, not retainable in memory.

magistracy of every district. Solicitation would immediately be in full activity, as these selected persons must be well paid; and after the whole nation had been thus disturbed, the fittest persons would not always be appointed. But to find every cottage in a rural parish, every separate family* in a town, requires local knowledge so exact and particular that the controller must be accompanied by an inhabitant in his censorship of the intended return of the censor first employed, and 15,000 other persons must be set in motion successively in the several parishes. Seldom would the second census exactly agree with the first; recourse must be had to some appeal for final decision, and a third census would usually ensue. But under this process the delay would be highly inconvenient, and the expense, which now perhaps averages at twenty shillings for each place, must amount to five times as much; for two persons must be employed in the second census, probably three in the third, besides that the controller must be a superior person, and paid accordingly; and 60,000*l.* or 70,000*l.* must be added to the 15,000*l.* now expended.

But supposing such increase of expense to be nothing compared with the value of precision, other objections of a weightier kind exist against such a judicial process. The overseers and churchwardens, who now perform their task with good will and alacrity, would be alarmed or disgusted at the foreknowledge that they were to incur formal responsibility—that their population inquiry was to be subjected to criticism and future question. "Is it not enough," they would say, or feel, "that we do our best, and, in submitting our returns to the magistracy, swear we have so done?—are we to be moreover liable to blame for accidental omission or mistake in a new duty, imposed on us for a purpose in which personally we feel little or no interest? We will not work on such conditions!" Thus the mainspring of the machinery, hitherto so successful, would be broken, and the population day, which now creates a sensation not beyond that of treading the parish boundary, would assume a severe character, and become unpopular among those who only can effectually execute the main intention of the population act. In reflecting on such difficulties, the reviewer would perhaps change his opinion, and grant that, in human affairs, the nearest practical approximation to truth is the best rule of investigation. He will even, I think, extend his charity to other parts of the population volumes of 1831; all which I think I could successfully justify in detail, though no more than one or two objections can be noticed in the limited space of a letter.

He says, for instance, that the area of an entire county is not made to correspond with that of its component parts. So say the Population volumes at the end of each county, and enable him to state the difference at 746 square miles in 57,812, or one part in seventy-seven; but as the public are not yet in possession of the entire ordinance survey (as he seems to suppose), this cannot be ascertained. For my part, I think I did good service in approximating (as far as materials were available) to the area of each parish; for it cannot be denied that the character of every place is indicated, in some degree, by the density of its population; and if the Poor Law Commissioners were asked the value of such approximation, added to the occupation columns, I venture to believe they would answer that their proceedings were much facilitated by reference to these particulars; and not the less because absolute precision cannot be ascribed to any part of the Population Inquiry. How much voluntary labour I bestowed in obtaining the best accessible knowledge of the area of every parish, the Population Preface may show (p. xxii.): the expense to the public was not less than 800*l.* additional, for materials and assistants in this particular branch of the inquiry.

I have ventured to say thus much as to the operation of enumerating the people, and the estimate of parochial areas, merely to shew that practical approximation ought not to be checked, much less superseded, until a detailed method of improvement is condescended upon (to use the Scottish phrase) by those who aspire at perfection; and I do assure all persons who may vouchsafe to write to me in that manner, that their proposals shall obtain respectful consideration, in so far as my influence may extend in framing a Population Act in 1840. They must

* How much does our language stand in need of the French word *ménage*, for population purposes!

bear in mind, however, that a national inquiry cannot be loaded with subordinate questions for private gratification.

The Edinburgh reviewer will, I am sure, forgive my criticisms, as being introductory to the above announcement; and I can sincerely avow my high opinion of the article herein mentioned, as containing an excellent epitome of British Statistical information, in which he goes far towards refuting his own opinion of its non-existence. Indeed, I cannot but think him too liberal, rather over-candid, in his depreciation of British statistics, as compared with similar knowledge on the continent of Europe. Permit me to imagine a French philosopher in the same liberal humour as the Edinburgh reviewer, and writing upon the same subject. "In France," he might say, "we have been miserably defective in the first element of statistics, in ascertaining our national population. In the time of Necker, we assumed a fictitious number, produced by an arbitrary multiple applied to the then imperfect register of burials. With the Revolution commenced a new æra, and the semblance of increasing population was founded on a higher multiple similarly applied. In fact, our population was never enumerated until Lucien Bonaparte became Minister of the Interior, under the First Consul. Before the termination of the war, another actual enumeration took place, but the result was not made public; and since the war, we have undergone two enumerations, the last of them nearly contemporaneous with the last British enumeration. But alas, so far are we in France behind all other nations in statistics, that the *sexes* have never yet been distinguished, and the relative number of males and females is entirely unknown. It is easy to understand why Bonaparte during the war did not exhibit the effect of his conscription law by such a disclosure; but why is this useful knowledge now withheld? In fact, we must confess that the genius of our government at all times tends to concealment, as much as that of our rivals in England tends to publicity."

Sweden has been honourably distinguished as the first nation attentive to inquiries as to the number of its actual population, and rate of mortality. The other northern nations, after some pause, have imitated Sweden, and at present, Prussia stands pre-eminent in such investigations. About fifty years since, Spain instituted an inquiry, which affords particulars of the then existing population far beyond example, even to the present time. Males, females, the married and unmarried, widowers and widows, the various grades of ecclesiastics and other classes, were carefully distinguished; but the misfortunes of Spain have thrown all this knowledge into oblivion, and very few copies of that Census are extant: but the splendid volume which contains the *Censo de la Poblacion de Espana* of 1797, institutes a comparison with the former Census; and therein preserves its most important results, as well as those of an earlier Census in 1796.

Some of the statistical inquirers on the continent, alluded to by the reviewer, are unquestionably meritorious and original; but they seem to be intermingled with as large a proportion of book-manufacturers as in England, whose confident statements must not be doubted, for certainly they cannot easily be confuted, because their authorities are not produced, when they venture upon any thing beyond avowed compilation from one or two original works.

In my next letter I propose to examine the details, and the probable amount of deficiency in English parish registers (which will become much more valuable if the ages of the enumerated population shall be ascertained a second time in the year 1841); and in adverting to parish registers, I shall again have to refer to the article in the Edinburgh Review, herein often mentioned; and much more to the article in that Review, published in March 1830; the best concentration of science and knowledge in population and the law of mortality which ever was presented to the public.

I remain, sir,
Your obedient servant,
JOHN RICKMAN.

PARALYSIS IN CHILDHOOD.

FOUR REMARKABLE CASES OF SUDDENLY INDUCED PARALYSIS IN THE EXTREMITIES,

Occurring in Children, without any apparent Cerebral or Cerebro-Spinal Lesion.

By JOHN BADHAM, M.D. Worksop.

CASE I.—Ann Hare, aged 2 years, was brought to me by her mother, on the 14th of August, with paralysis of the

right leg. Her account of this seizure was as follows:—

The child had enjoyed uninterrupted health to the evening of her attack, with the exception (if, indeed, it can be so called) of slightly augmented thirst and some drowsiness, now remembered by the mother to have preceded the seizure by two days. On the evening of the 13th the child was put to bed, having run about and amused herself as usual during the day. On the following morning her mother's attention was first attracted, in dressing her, to an unusual appearance of the eyes, which, as she said, appeared to be turned inwards. A new cause of apprehension presented itself in putting the child on her feet, when it was found she could not stand. Medical advice being immediately sought for, it was thought sufficient, I understand, to keep the bowels open and to employ a warm-bath. No advantage, however, being procured under this treatment, she was brought to me on the 14th; a week after her attack. Her *appearance* at this time did not denote *any* disease—she was playing in her mother's lap; but on accurately examining the two limbs, it was found that *motion* in the right was completely destroyed, and in the left somewhat diminished; while *sensation*, perfect in the left limb, was impaired, without being suspended, in the other. At this period there was neither wasting of the limb nor diminution of temperature. Strabismus very decided; the pupil drawn to the inner canthus, and the eyeball fixed there, as I found in attempting to direct the vision outwards, and the pupil on the same side as the palsied limb was dilated. No disturbance of constitution could be traced from teething, or from torpor of the bowels; nor, on examining the spine attentively, could I detect any tenderness on pressure. I directed calomel in repeated doses, cold applications to the head, blisters to the spine, and cataplasms to the affected limb. Under this treatment the drowsiness was removed in five days. On the fourth, indeed, from its adoption, the ball of the right eye became suddenly liberated from its constrained position; the other eye recovered more slowly, a few days afterwards. The limb now shows (on the 15th of October) some return of sensibility, but the temperature is considerably below that of the other, and loss of substance has proceeded to a considerable extent. The exercise of the will over the affected extremity, though entirely abolished at first, has now partially returned, inasmuch as she no longer drags the limb after her, as she at first did, but projects or flings it forward with a jerk, the direction and force of which she seems not to have the slightest power to moderate or control.

Case II.—My second case singularly occurred a few days afterwards; its subject a little girl, also 2 years old, who had been seized, a week previously to my seeing her, with an equally sudden loss of the same extremity; which took place also during sleep, without any prior intimation. Thirst, remarked also in the former case, was a more prominent symptom in this; and the mother thinks there may have been somewhat more drowsiness about the child than common. The pupil of the left eye was dilated; the eyeballs free in their sockets; and, indeed, this unimpaired mobility constituted the only marked difference between the two cases. This case was chiefly treated with strychnine externally applied, but without any benefit; nor did stimulating embrocations and mercurials meet with better success. The perfect contractility of pupil was soon recovered. but the limb remains perfectly palsied and useless, though sensation has been somewhat restored.

Case III.—My attention has been a third time arrested by a case analogous in all its material points to the two just cited, except that the paralysis here is of the *upper* extremity. The patient, a girl, aged 2 years and some months, without any previous fit or other appreciable cause, was found one morning to have lost the use, and a great portion of the sensibility, of the left arm, which was swollen throughout its extent, the right arm being also implicated, though to a very inconsiderable degree. The right pupil is much dilated, the left is contracted; the evacuations from the bowels have been dark and offensive. No tender spot can be perceived on the spine; all the functions are healthy.

This case was also treated with strychnia, preceded by smart purgatives of calomel, &c., and with no better success than the last. The limb is now, after the lapse of nearly two months, hopelessly paralysed, and swings like a suspended object attached to the body.

Case IV.—John Hollis, a little boy

of 2 years and a half, was lately seized with exactly similar symptoms to those above described. The action of the left lower extremity entirely lost, sensation much diminished; the temperature of the affected limb is diminished, and it is somewhat reduced in size, the muscles being more flabby than those of the other limb.

1. The extraordinary youth of the patients is to be noticed. It will be observed that the age in all the above cases corresponded within a few months.

2. Although each case was either preceded by or ushered in by some apparent cerebral symptoms—viz. in two by drowsiness, in the others by an abnormal state of the pupil—yet

3. It is remarkable that in no one instance has the health been in any degree impaired.

4. If the case in which the remarkable strabismus occurred should lead us to suspect a cerebral complication, rather than a spinal one, there is other suspicion of congested, oppressed, or irritated brain.

The above cases (of which the first was seen some time ago by Dr. Outram, and three of the four subsequently by my father, Professor Badham), may probably suggest analogous ones in the experience of some few of your readers, who may also be able to help me to a treatment from experience; for we know nothing of the intimate character of any species of palsy, so as to manage it philosophically, and to adopt a medication without a defined object. A view which admits of being stated in intelligible language, is scarcely medicine. Some would doubtless in these cases recommend issues; some would counsel electricity; others would put me in mind of Arnica, or other *soi-disant* remedies for palsy; but I am unwilling to disturb the digestive and nutritive functions in such young subjects, and would rather count on these important processes as my auxiliaries, than venture on equivocal remedies which may, or rather must, depress them. I shall be thankful, however, for any suggestion; for it is lamentable indeed to witness one of the most humiliating infirmities of age inflicted on infancy! Perhaps one may reasonably expect some of the little patients to outgrow their disastrous condition, unless it shall be concluded that palsy in such instances is only an unusual and early evidence of deeply latent cerebral mischief.

Case of Diffusive Cellular Inflammation of the lower Limb, successfully combated by Calomel, Turpentine, and Leeches.

Ann Hudson, aged 4, was brought to me late one evening, when the following notes were made:—The child had been attacked three days before I saw it. The right limb much swollen, inflamed, burning hot, and pitted on pressure; the integuments shining; their colour a dusky red. The mother had traced the erysipelatous tumor, for such it is, *from a small spot or pimple under the knee*, which came, she said, spontaneously, and without injury. Febrile symptoms are now urgent; voice shrill; head seems much affected, and the hands are frequently raised to it; there is constant moaning, and no sleep since the seizure. The inflammation extends half way up the thigh, but the most intense redness is below the knee. The bowels have been opened, but no relief has resulted. The tongue is moist, but with a dark fur. Leeches were applied, and to encourage the bleeding the limb was enveloped in a poultice made with spirit of camphire, &c.

Eight grains of calomel were directed to be taken immediately, and two grains every two hours afterwards till seen again; and a terebinthinate purge and enema administered.

Aug. 24th.—The tumefaction is now checked and stationary, but the redness and general pyrexia not diminished. Bowels not yet freely opened; the moaning continues. An almost mathematical line separates the inflamed and healthy cutis. Lest it should be transgressed, ordered this line to be pencilled with lunar caustic, and the calomel to be repeated every four hours, with a repetition of the terebinthinate draught and enema. Towards evening eight more leeches were applied on the most inflamed parts.

25th.—A more quiet night resulted; less moaning and fever, and tongue cleaning; the limb, or that portion circumscribed by the caustic, has still a red and dusky colour, and is very hot, and the integuments tense. Fever becoming higher in the evening, I ordered two free incisions through the integuments and cellular tissue, and spirituous fomentations.

26th.—This day every urgent symptom subsiding; tongue cleaning; bowels freely purged; skin cool, &c. Had refreshing sleep during the night, and all subsequently went on well.

I had a strong reason for the activity of treatment here adopted. This child's brother, a year older, had been seized in a precisely similar manner, and like it, from some constitutional peculiarity, without any obvious or external exciting cause. I had been called to see it when both legs were much distended, and large effusion had already taken place throughout the cellular membrane. Cerebral symptoms were clearly denoted by a stupor and a moaning when disturbed (for otherwise it would lie and complain not) increased the alarm. To all this excitement a state of collapse suddenly supervened. The child died. At its very commencement I had predicted this fatal issue, from having treated three similar cases in black children in the West Indies, none of which had excited my apprehension at their commencement. I verily believe the child whose case I have given to have been unequivocally saved by the treatment; and I believe these cases of diffusive cellular inflammation end, when fatal, by effusion in the brain.

Worksop, Notts,

ACCOUNT OF A CANADIAN MEDICAL SAINT,

AND HIS METHOD OF PRACTICE IN CHOLERA.

To the Editor of the Medical Gazette.

Sir,

In the Lancet of the 10th instant is contained a communication which has the following statement:—" In the summer of 1832, when the cholera was devastating the Canadas, *a tattered old man* appeared in Montreal, whom the Catholic populace were induced speedily to canonize for his *successful treatment* of this disease, which was at that time almost as mysterious to the population as the stranger himself. To this modern saint vast numbers of the infected were brought, who were *restored to health from the most violent attacks of the inflammatory stage, as well as the worst possible collapse*, even after the duly authorised practitioner had exhausted and relaxed his efforts. The remedy consisted of a due admixture of maple-sugar, charcoal, and lard, which melange was given to his patients in large quantities after every ejection. The results were astonishing, and could be indicated in the speedy alteration of the countenances of the sufferers, and the early subsidence of vomiting and purging."

Now this " tattered old man," as he is here called, I happen to have personally known. His name was Ayres; he came out of the States, and was said to be a graduate of the University of New Jersey; but I never heard himself say that he possessed the latter distinction. He, however, appeared unexpectedly and oddly, giving out, or causing it to be given out, that he was St. Roche, the principal patron saint of the Canadians, and that he had descended from heaven to cure his suffering people of the cholera. Nor did he fail of doing good by this means; for the bigoted people think every thing of their saints and priests, and nothing of any body else; therefore he in a great measure cured them of fright, which was five-sixths of what he had to do. As he took no money for his pains, he of course had plenty of patients, and a great fame; and the doctors (some of whom afterwards fell martyrs to their exertions during this period) were not a little pleased to find him easing them of the most unpleasant part of their burden.

The writer does not give the whole of Dr. Ayres' plan; for in addition to the maple-sugar, charcoal, and lard, he had the patient rubbed with lye-water, and gave him plenty of soup (broth rather) to drink; also water in which hot charcoal had been immersed. But now, as to his cases and success.

The great mortality from cholera at Montreal was in the first three weeks after its appearance; during which time, as all was consternation, and Dr. Ayres's fame fresh, of course every recovery where he had been called in was trumpeted as a case of recovery from spasmodic cholera; and I fear that the writer of the communication alluded to rests somewhat on popular report for his information, when he says, "vast numbers of the infected were brought, who were restored to health from the most violent attacks of the inflammatory

stage, as well as the worst possible collapse, even after the duly authorised medical practitioner had exhausted and relaxed his efforts." But if he was on the spot at the time, and witnessed what he relates, I can only attribute it to the confusion which prevailed, that I was not able to obtain similar evidence. Now Dr. Ayres's patients were nearly all Roman Catholics, and he was constantly going among them as fast as the best Canadian horses and gigs could carry him; so that there could have been comparatively few of them whom he did not see: yet the Roman Catholic burials in that year amounted to 2732, whereas they were only 989 in the year previous; and of the whole population (of which the Protestants make comparatively a small part), the number of deaths in three months and a half during the progress of the cholera, was very nearly equal to the annual average in the nine preceding years.

But as to the nature of the disease which Dr. Ayres generally treated; I contend that his successful cases were not spasmodic cholera at all. Ever since that period until November of last year, I lived on the spot; knew the Saint; had frequent opportunities of conversing with him, and ever made the most diligent inquiry concerning his practice of every one who was in the least measure able to afford information; and yet I never could be shewn any man, woman, or child, whom he had cured of spasmodic cholera. There was scarcely any case of his which recovered that differed at all from the ordinary summer diarrhœa of the country. He commonly said, when called to a real case, "It is too late,—you did not have me soon enough." And although he for some time held up my friend, Mr. Forsyth, of Montreal (who in his anxiety obtained his advice) as a subject of recovery, it clearly appears that Mr. Forsyth's case, although it would have been looked upon suspiciously by any medical man at first, yet had not in it one infallible symptom of spasmodic cholera. The trick, however, became so well understood, and the Doctor's disinterestedness so generally suspected, that upon his presenting a petition for remuneration to the House of Assembly in the following January, it was wholly rejected, notwithstanding that the members are almost entirely native Canadians. But I can yet speak more to the purpose on this point:—The first cases of cholera which came under my notice, were among the raftsmen, on the Ottawa. I had never seen the disease before, and being in an uninhabited part of the country, without any other medical person to consult with, felt anxious to try every thing which was spoken of as at all successful. I accordingly obtained Dr. Ayres's prescription from himself, and, as the ingredients were at hand, had a large quantity of this ointment-medicine prepared, and gave it out to every body who asked for it. However, both this and every other means which I tried completely failed there, and I did not save a single case. I was shortly ordered to Quebec, to assist the medical officers in that garrison; in a week after which, a Serjeant Evans (of the Royal Staff corps), and a servant of my own, both healthy young men, with three children of the former, and several women belonging to a small detachment left behind, became martyrs to the charcoal system.

But Dr. Ayres had another chance of displaying his powers; for, in 1834, Montreal was just as badly off from the cholera as before; and the disease, at this latter period, carried off more people of high rank, who had every facility of employing him, if his fame had stood the test of public opinion (for he remained in the neighbourhood, and, notwithstanding his person and circumstances, had succeeded in marrying one of the fairest Canadian damsels resident there, and who was also one of the first-fruits of his miraculous powers), yet nobody thought of calling him in; and his obscurity was only to be contrasted with his former renown. How shocking, that, in one month and a half, thirteen hundred and twenty-five people should have died, and he in the midst o. them!

I do not profess to know what share his medicines might have had in curing the cases of diarrhœa, which he treated as cholera, or how much the confidence he inspired prevented the former from running into the latter disease; but every one knows, that, from the days of Celsus to the present time, diluents have proved highly instrumental in curing diarrhœa, and hence the value of his soup;—added to which, the practice of producing vomiting, by whatever

means, greatly assists in curing the disease in that particular country, which was effected by his huge balls of lard.

I am, sir,
Your obedient servant,
J. FARR.

Woolwich, Oct. 29, 1835.

MISCELLANEOUS CASES IN PRACTICAL SURGERY.

To the Editor of the Medical Gazette.

SIR,

THE following cases have occurred, within the last six weeks, in my practice; and as they present some points of peculiarity, you will probably deem them deserving of a brief record.

I am, sir,
Your obedient servant,
T. F. PALMER.

38, Golden Square,
Nov. 5, 1835.

CASE I.—*Irritable Stump, arising from the inclusion of the Fibular Nerve in the Cicatrix, in consequence of which its extremity became bulbous.*

W—— C——, æt. 52, had his leg amputated on November 23, 1832, at the usual distance below the knee, on account of an accident which had crushed the inferior parts of the limb. About nine months after the operation, the patient began to experience twitches and cramps of the muscles of the stump, which gradually became more severe until August 1834, when the surgeon who had amputated the limb removed a portion of the fibula, conceiving that this might be the cause of irritation, as it was more prominent than it ought to be. No relief, however, was experienced from the operation, but, on the contrary, the symptoms continued to increase so as to render the patient's life truly miserable, partly from the pain which he suffered, and partly from the deprivation which it occasioned of his natural rest. At the time that he applied to me, the muscles of the stump and thigh were incessantly agitated by the most violent muscular contractions, attended with the usual pain which accompanies cramp. Having examined the cicatrix with great care, I found a minute papillary projection at the lower part, which, from its excessive sensibility, I had no doubt was the extremity of a divided nerve; so that I had no hesitation in immediately recommending its removal, as the only effectual mode of getting rid of the painful annoyance. The operation by which I accomplished this, I performed with the assistance of my friend, Mr. Ford Copeland, of Argyll-street. I insulated the nerve for about half an inch, and removed it. The trunk of the nerve, I found, was about twice its natural size, terminated by a bulbous extremity, about twice as large as the nerve itself.

The relief which has been afforded by the operation is not absolutely complete, for the stump is still occasionally agitated by slight spasms, and the nerve, for above two inches above the cicatrix (as may be perceived by feeling through the external integuments) is still enlarged, and very sensitive. Unquestionably the relief which has been afforded is immense; but I now regret that I did not, in the first place, remove a greater length of the nerve, so as completely to obviate the possibility of its being again involved in the new cicatrix.

CASE II.—*Hæmaturia, in which five pints of bloody fluid were evacuated from the Bladder at one time.*

On the 5th of October, 4 P.M., I was requested to visit D—— T——, æt. 45, who was represented as labouring under retention of urine. When I entered the apartment, I was forcibly impressed with the look of anxiety and distress depicted in my patient's countenance, which appeared to me to indicate that serious mischief had already taken place. I found that an irritation of the urethra, attended with strangury, had come on on the preceding morning, without any apparent cause, which, in the course of a few hours, terminated in complete retention of urine, characterized with the usual symptoms of ineffectual straining. He lay in this state for upwards of twenty-six hours, at the end of which time the bladder (which was much distended) projected considerably beyond the umbilicus, attended with a plain sense of fluctuation. I immediately introduced a large silver catheter into the bladder, and drew off five pints of bloody, grumous, highly offensive matter, which had nearly the same consistence as the fluid which is evacuated

from ovarian dropsy, and was neither acid nor alkaline to tests. I afterwards repeatedly injected the bladder with tepid water, until it ceased to be discoloured; ordered a large opiate draught, and directed my patient to return to his bed; and in the course of two days he was perfectly recovered. No coagula were observed in the fluid.

On the 25th of October, that is, just three weeks after the preceding occurrence, he was seized with acute pain in the small of his back, stretching down to the groins, attended with numbness of the left thigh, retraction of the left testicle, and sickness. These symptoms lasted for four hours, and then completely went off. I conceive, therefore, there can be no obscurity respecting the source of the hæmorrhage in the first attack. It can scarcely be doubted that a renal calculus became dislodged from some cause from its nidus in the kidney, and abrading the pelvicular mucous lining, occasioned an effusion of blood into the bladder. A further change in its situation on the 25th, probably led to its descent through the ureter, and final expulsion from the bladder.

The small quantity of urine which was mixed with the effused blood, may be accounted for by the hæmorrhage, which, when considerable, always occasions a more or less complete arrest of the action of the kidneys. I am at a loss, however, to understand the reason why the blood did not coagulate in the bladder, or, not being coagulated, why it was not promptly evacuated.

Case III.—*Epilepsy from Venereal Enlargement of the Cranium, cured by the operation of Trepan.*

J—— B——, æt. 35, requested my advice on the 24th of October, 1834. She complained of intense recurrent headaches, situated over the right temple, accompanied with a few lichenous eruptions over the arms. The cranium, at the part to which the pain was principally referred, was exceedingly tender to the touch, but there was no swelling or apparent inflammation. From the history which I was able to extract from her, there could be little doubt that her husband had inadvertently communicated to her the disease, and that the symptoms which she complained of had a venereal origin.

I shall not, however, occupy the time of my reader with detailing all the circumstances of the case, or the various modes of treatment which were had recourse to without effect. Suffice it to say that they none of them afforded more than partial or temporary relief. The eruptions, it is true, on the skin disappeared after a few weeks, but the pain and tenderness of the head became daily more aggravated, until, towards the beginning of the present year, she was seized first with fits of temporary forgetfulness, then with attacks of fatuity, and finally with epileptic paroxysms, which, as time wore on, became more frequent, and lasted for a longer time.

In March I divided the integuments of the forehead down to the bone, which afforded complete relief from the fits, and partial relief from the headaches, for six weeks; but the slight caries which resulted from the operation soon healing over, and the fits recurring with redoubled severity, I was now compelled to remove a circular portion of the scalp, with a view of encouraging a plentiful suppuration from the bone, and giving a free egress to the matter. This also arrested the fits for a few weeks, but after a while they recurred again, and were a third time relieved by a seton in the neck, which procured for her a more complete respite than she had yet enjoyed. This, however, did not last.

About the middle of September, as she was walking in the street, she was seized with complete hemiplegia of the left side, without, however, losing her consciousness, or the occurrence of any convulsions. The hemiplegia was relieved by venesection and cupping; but the fits now recurred more frequently than ever, so that on the 3d and 4th of October, she scarcely recovered from one fit before she fell into another.

Finding that no relief could be given by other means, and being apprehensive, from the degree of cerebral excitement, that effusion on the brain would speedily ensue unless something was done, I determined on trepanning the frontal bone, which operation I performed on the 5th of October, with the assistance of my friend, Mr. F. Copeland. I found the cranium more than twice as thick as it is naturally, and firmly adherent to the dura mater. She had one severe fit within two hours after the operation, and another on the following morning,

since which time she has been perfectly free. The dura mater, as I expected it would do, sloughed opposite to the opening made into the cranium, but without any unpleasant consequences. The parts are now firmly incarned over, and the danger of a hernia cerebri entirely past. The patient declares that she has not felt so well for the last two years.

I thought it probable, when I undertook the operation, that matter might have formed between the dura mater and bone; and it was only upon the chance of finding this state of things that I recommended the operation. In this, however, I was mistaken; the dura mater was firmly adherent, and perfectly healthy; so that I can only account for the relief which has been afforded by supposing, first, that an inconsiderable degree of pressure, arising from the thickened cranium, has been removed; and secondly, that the free discharge proceeding from the diseased part, may act as an excellent counter-irritant, and at the same time tend to reduce the thickened bone. I do not, however, contemplate that the relief will be effectual or lasting.

ON ANIMAL HEAT AND VITALITY.

IN REPLY TO DR. WILSON PHILIP'S LETTER.

To the Editor of the Medical Gazette.

SIR,

ONE object of my last letter was to disclaim any attempt to decide on the still disputed points concerning the nature of the nervous influence, and its relations to secretion and muscular action. Dr. Wilson Philip, in his last communication, regrets that I decline entering upon these questions; and I can assure him that my indisposition to do so proceeds neither from "indolence of mind which shrinks from difficulties," nor from want of interest in the subject; but from the conviction that, until we have more decisive facts than those which we at present possess, discussion will be as fruitless and as unconvincing to future as it has been to former arguers. Many of your readers must be aware how much these subjects have been debated, from the time of Whytt and Haller to the present day; and although no one denies that the experimental researches of Dr. W. Philip, and other recent inquirers, have greatly increased the precision and extent of our knowledge in these matters, yet we find standard physiological writers not only differing from Dr. Philip in his conclusions, but stating that the province of the nervous system in producing the phenomena of life, were more accurately understood by Haller*.

So far from conclusive, so little convincing, have been the numerous experiments of modern physiologists, that it would be difficult to find any two authors who entirely agree in their deductions from them; and the proverb, "quot homines, tot sententiæ," may, with peculiar aptitude, be applied to the investigators of the functions of the nervous system. To give a brief example.

The researches of Dr. Wilson Philip are, I believe (though he appears not to think so), well known to the reading part of the profession: yet Drs. Bostock, Alison, Henry †, and others, while they assent to his conclusion that muscular irritability is independent of nervous energy, do not admit his views of the nature of the nervous influence, or of its relation to the processes of secretion and nutrition. Mr. J. W. Earle, on the other hand (the latest writer on the subject), rejects Dr. Philip's conclusion, which the authors just named admit, and adopts those to which they refuse assent; except with regard to the nature of the nervous influence, which he also holds has *not* been identified with electricity. Thus, with the addition of a tribute to the improved state of physical science, we find revived the old discussions of Whytt and Haller, in which the student of the history of medicine may learn how inconclusive are discussions, and even experiments, in physiology, when founded on a preconceived and favourite system.

After these declarations, the majority of your readers will excuse me if I decline entering on the much trampled arena of *nervous* discussion; and in the following comments on certain points of Dr. Philip's letter, as well as in my former communications, my wish is to preserve a neutrality with regard to opinions concerning the influence of the nervous system on the processes of

---

* See Preface to 2d edition of Professor Alison's Outlines of Physiology, and Dr. Bostock's System of Physiology, vol. ii.

† Third Report of the British Association, &c.

secretion, nutrition, and muscular action.

On this ground, in my last letter, I did not deny the power of the spinal marrow to produce heat; but I stated that its share in this process is hypothetical. It is on ground disputed in the general questions of nervous agency, from which I purposely keep aloof. I will merely observe, that the same "direct facts" which Dr. Philip considers to prove that the spinal marrow contributes to maintain animal heat, have been associated, in Dr. Marshall Hall's observations, with failure of the capillary circulation*. I am quite aware that certain injuries of the spinal marrow, or of any other part of the nervous system, will cause a depression of animal temperature; but whether this effect is direct, or intermediate through functions which such injuries to the nervous system paralyze (as a crushed limb will stop the heart's action), is an unsettled question. Thus, also, Chossat (whose excellent memoir is less known than it deserves to be) found that bruising the semilunar ganglion of the great sympathetic nerve, or tying the aorta below the diaphragm, was followed by as rapid a diminution of animal heat, equally in the œsophagus and rectum, as could be caused by removing the brain or spinal marrow †.

The following paragraphs contain a position which may be commented on without treading on the questionable ground:—

"The confusion which prevails on this subject cannot, I think, be better illustrated than by the circumstance of a person so well acquainted with it as Dr. Williams supposing that animal temperature *can in any degree be maintained* by the functions of circulation and respiration after the influence of the nervous system is wholly withdrawn." "When the nervous influence is wholly lost, the mechanical parts alone of circulation remain. It is impossible, under such circumstances, that *any degree* of animal temperature can be maintained, the chemical part of the vital functions wholly depending on that influence."

Now it would be in vain for me to seek support for my *supposition* in any experiment on the body of an animal. Although I might destroy the whole brain and spinal marrow, and then find that artificial respiration still retards the cooling of the animal, yet this process, and the circulation that it maintains, would get no credit for the heat generated; for under these circumstances Dr. Philip says, "whether the brain or spinal marrow exist or not, there is already in the *nerves* more nervous power than the blood can use*." But if I remind Dr. Philip that some heat is evolved from *blood out of the body*, both during and after the absorption of oxygen, *from changes merely chemical*†, which, as far as we know them, resemble those which take place in the body, and that the temperature of the blood in the body, and its perfect exposure to the air by respiration and circulation, must greatly promote these changes, will he not admit that I have some ground for "ascribing to the functions of respiration and circulation the power of generating heat, although to small extent, unless supported by other functions‡?"

The latter part of Dr. W. Philip's letter contains remarks with many of which I entirely agree; but as far as regards myself, they are unnecessary, since they arise from a misinterpretation of a sentence in my former letter. "Whilst we admit the possibility of electricity having properties yet unknown which may hereafter explain the various processes of organic life, we must for the present content ourselves with referring them to a cause of which we confess our ignorance by calling it vitality." The real meaning of "our ignorance of the cause" may be explained by placing the phrase in opposition to a sentence from the commencement of Dr. Philips's letter: "Till the functions of the sensorial and nervous powers are clearly distinguished, and *the nature of the latter ascertained*, all discussions respecting them must more or less be, as they have always hitherto been, involved in error and consequent confusion."

In conclusion, I again disclaim for my views respecting the changes of the blood and animal heat, a necessary connexion with any of the various opinions

* On the Circulation of the Blood.

respecting the nervous influence and its province in the phenomena of life. I have, indeed, referred to facts connected with this subject, but the interpretations of these facts have been excluded as doubtful; and if in two or three passages the words nervous and vital have been too indiscriminately used, a correction of these terms will not injure the tenor of the arguments. My views of the cause of animal heat are not inconsistent with those of Dr. Wilson Philip, since he no longer terms animal heat a *secretion*. The object of our inquiries are distinct: his refer to the vital functions which determine the evolution of animal heat; mine to the chemical changes which are its immediate cause.—I am, sir,

Your obedient servant,

CHARLES J. B. WILLIAMS.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Friderici Arnoldi Icones Nervorum Capitis Heidelbergæ. 1834. Folio. Baillière.

THESE are at once the most beautiful, accurate, and economical plates of the nerves, which we have seen. Their number is nine, each accompanied by an outline, with numerals; and the price is but thirty-two shillings. They are, at the same time, strict copies from nature, and interesting specimens of the lithographic art. The author says, in his preface, "Summa religione affirmare possum, nulla filamenta in iconibus pro nervis recepta esse, quorum natura dubitationis ansam præbuerit." He then enumerates the points in the anatomy of these nerves of which he is the discoverer, viz. the otic ganglion, the auricular branch of the vagus, the recurrent of the first branch of the fifth, the nervus petrosus superficialis minor, the gangliform enlargement of the facial, and the conjunction of the sympathetic with the auditory. The author adds, lastly, "Omnes compilatores oro atque rogo, ne tangant has tabulas;" and states how injurious incorrect copies of such plates become to the cause of science.

We shall proceed to detail the principal of the author's views of the nervous system. They will be found, we are persuaded, to be full of interest.

Nerves of different kinds are distributed to the head, on account of its numerous and important organs. The cerebral nerves, the four superior cervical, and the highest portion of the nerves of the vegetative system, belong to this region of the body.

The head is the seat of the sensorium. The organs of the senses are situated in the head; those nerves prevail, therefore, in the head, which belong to animal life. The reverse of this is observed in the abdomen; for the vegetative system prevails in the region of the viscera.

The nerves of the ganglia are principally distributed to the arteries; the cerebral and spinal nerves, to the voluntary muscles, and to the organs of touch. The cephalic portion of the sympathetic nerves gives many filaments to the carotids, external and internal, and to the vertebral arteries, and forms several conjunctions with the cerebral and spinal nerves. The four superior cervical nerves are distributed upon the occiput and neck; the cerebral nerves, upon the cranium and face, and the organs attached to each of them, upon the larynx and lungs, the œsophagus and stomach.

Twelve pairs of cerebral nerves have been enumerated from the time of Sömmering. Their denominations are as follow:—1, the olfactory; 2, the optic; 3, the oculo-motory; 4, the trochlearis; 5, the trigeminus; 6, the abducens; 7, the facial; 8, the acoustic; 9, the glosso-pharyngeal; 10, the pneumo-gastric; 11, the accessory of Willis; 12, the hypoglossal.

All the cerebral nerves may be aptly divided into two classes: the first comprises the nerves of sense, properly so called; the second, the *intervertebral* nerves of the cranium. The first (the olfactory), second (the optic), and eighth (the acoustic), belong to the first class; the rest, which, like the spinal nerves, have a double, anterior, and posterior root, belong to the second, take their origin from the brain, and pass between the vertebræ of the cranium.

The intervertebral cranial nerves may be subdivided into two *pairs* : of these, the third (oculo-motory), together with all which follow to the seventh (the facial), forms the *anterior pair;* the ninth (the glosso-pharyngeal) to the twelfth (the hypoglossal) inclusive, constitute the *posterior pair.* The *posterior root* of the anterior intervertebral pair is the large portion of the fifth pair (trigeminus); the *anterior root* is constituted by the third (the oculo-motory), the fourth (trochlearis), the sixth (abducens), and the minor portion of the fifth, or the masticatory. The *anterior root* of the posterior pair of intervertebral nerves comprises the eleventh (the accessory) and twelfth (the hypoglossal): the *posterior root*, the tenth (the pneumo-gastric). The cerebral nerves may, therefore, be arranged thus:—

Class I.—1st, 2d, and 8th pairs.

Class II. ....

Roots.	The Intervertebral Nerves, viz.:— The Anterior.	The Posterior.
Anterior.	3d; 4th; 6th; minor portion of the 5th; 7th pairs.	11th; 12th pairs.
Posterior.	5th pair.	9th; 10th pairs.

The cerebral nerves may be divided in another manner:—The nerves of the anterior and posterior intervertebral pairs are *mixed*, *i. e.* are *motor* and *sentient*, or *simple*, *i. e.* are *motor* only. To the *former* are to be referred the fifth (trigeminus) and seventh (the facial), the tenth (the pneumo-gastric), with the eleventh (the accessory), and the ninth (the glosso-pharyngeal); to the *latter*, the third (the oculo-motory), the fourth (the trochlearis), the sixth (the abducens), and the twelfth (the hypoglossal).

In this point of view the cerebral nerves may be distributed thus:—

Class I.—1st, 2d, and 8th pairs.

Class II. ....

The Intervertebral Nerves, viz.:—	Mixed Nerves.	Simple Nerves.
The Anterior.	5th, 7th pairs.	3d, 4th, and 6th pairs.
The Posterior.	10th, with 11th, 9th pairs.	12th pair.

Of the cerebral nerves, the third, fourth, and sixth, move the eyes; the twelfth, the tongue; the fifth gives sensation to the face, the nostrils, the mouth; the tenth, to the œsophagus, the larynx, and the lungs. To the fifth is added the minor portion, as the masticatory nerve; to the tenth is added the eleventh, as a vocal and respiratory nerve. The larger portion of the seventh is the motor nerve of the face; its minor portion is a nerve of sensation. The ninth pair, by its greater part, gives sensation to the root of the tongue and to the pharynx, and by its minor portion moves the pharynx.

The nerves of the first class differ from the other cerebral nerves in their structure, formation, and vital property; they give off no branches in their course; they resemble the cerebral substance in structure more than the intervertebral nerves; they proceed, in the fœtus, from the cerebral cells; they perceive some irritants alone, as odours, light, and sound.

The intervertebral nerves resemble the spinal nerves; both their anterior

and posterior roots arise from the cerebrum: the posterior root is furnished with a ganglion, of which the anterior is destitute; the posterior consists of many fine filaments which extend to the ganglion; the anterior, although it arises in several filaments, immediately forms a round trunk. The intervertebral nerves give off filaments in their course, and in the organs into which they penetrate. They are not formed by the cerebrum or spinal marrow, but *per se* at the point of origin; they perceive various irritations, so that they excite either muscular motions or sensations; the anterior and posterior roots convey their impressions in different directions. Since, therefore, one series of the nerves conveys the conditions of the brain and spinal marrow to the organs, so as to excite motions, whilst the other conveys external impressions and the affections of organs to the central parts, the intervertebral nerves may be divided into motory and sentient. The anterior root of the spinal nerves belongs to motion, the posterior to sensation. How much certain cerebral nerves belong to the former, and certain others to the latter of these, I have learnt (says the author) by the most attentive anatomical investigation.

By the cerebral nerves, a connexion is established between the sensorium commune and the external parts of the head, the lungs, and the stomach; the mind is, as it were, conveyed to these organs, and the sympathies and mutual influences of the internal parts are effected. The cerebral nerves convey impressions from objects perceived to the mind and constitute sense, or the acts of the mind to distant parts, and excite motions. The different functions of these nerves depend upon their nature, that of the particular part of the brain, and that of the external organ. Thus the trunks and filaments of nerves have, in the first place, different functions from their very structure: the true nerves of sense differ in structure, both from each other, and from the fifth and tenth; the motory nerves differ from the sentient. Thus each part of the brain, from its own structure, is allied to sense or motion, and communicates this or that property to the nerves which arise from it. Lastly, the organs themselves are allied, in their nature, to this or that property of the cerebrum.

The more complicated are the relations of an organ with the brain, the more numerous are its nerves, and the more various their origin and nature. The head comprises many important parts, and its nerves are proportionately numerous. The cerebrum and cranium, which exhibit, in their origin, the normal structure of the spinal marrow and the vertebræ, have undergone such a change in man, that the parts of each nerve are so separated in their origin and course, that many nervous trunks are found, of which the primitive and normal character will only be learnt by the laborious anatomist.

It must be well known to our scientific readers, that the cranium has been traced as being formed of bones compared to *three vertebræ.* These, of course, leave *two intervertebral spaces.* Through these the intervertebral cerebral nerves are supposed to pursue their course, maintaining a general analogy with the intervertebral spinal nerves, being divided only from the varied *forms* of these cranial vertebræ and their intervertebral spaces. There are still some difficult points in the theory; and there is especially great difficulty in imagining that all nerves are either nerves of sense, or of sensation and motion. The nervus septi narium and the pharyngeus, branches of the fifth, and some parts of the pneumo-gastric, present this difficulty. But we must not enter into this abtruse question at the present moment.

A Treatise on Poisons, in relation to Medical Jurisprudence, Physiology, and the Practice of Physic. By Robert Christison, M.D., Professor of Materia Medica in the University of Edinburgh, &c. Third Edition. 1835.

We are glad to find that this excellent work has now reached a *third* edition. It betokens a fully awakened and growing ardour, on the part of the profession, for the eminently interesting subject of which the volume treats.

Nor have the four years which have elapsed since the previous edition, been unproductive of material for the improvement of toxicology; they have enabled the author to add many new illustrations of the principles which he already advocated, and to introduce a few subjects altogether new.

It is by no means our intention to give a lengthened notice of a work so well known: enough for us to announce that it has once more re-appeared, in an improved state. But we must add, that we can give Dr. Christison large, if not unlimited, credit for his vigilance and industry. We have traced him closely over several parts of his new ground, and no where have we detected him loitering or negligent; no where have we found any thing omitted which had the least show of practical utility to recommend it. Of course a notice of the chief points connected with the late Bristol medico-legal case is given; and we perceive that the author entertains much the same opinion that we do regarding the vaunted hydrated tritoxide of iron as an antidote for arsenic—namely, that it simply acts mechanically; he thinks, however, that the tritoxide may be occasionally of use, by enveloping the coarser powder of the arsenic with its fine, impalpable, and adhesive particles.

MEDICAL GAZETTE.

Saturday, November 14, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri: potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

GERMAN UNIVERSITIES—IMPORTATION OF DEGREES.

"It is not every man's lot," said the old adage, "to go to Corinth;" so that it must have been the fate of many in the olden time to be content with merely hearing of Corinth. At the present day, with all our boasted and acknowledged conveniencies by steam-boats and other flying machinery, it happens to the great mass of our profession to have little personal acquaintance with what goes on in other countries; but as we have abundance of travellers who contrive by

"Using limbs instead of head,
To have seen what we have read,"

we may be at once amused, and even reconciled to our privations.

Medical travellers, however, are rather scarce; or when they do make their appearance, we generally find them otherwise occupied than in drawing up notes for their more quiescent and home-keeping brethren. We must be, acordingly, grateful, we suppose, when any of them deign to think of us, and to write a book for our entertainment.

Mr. Edwin Lee has recently produced such a book*, and we are much deceived if it fail to interest most of those who look through it. The author visited almost all the principal seats of learning and medical science in France, Italy, and Germany; and the account which he gives of them is so sketchy and animated, that the chief fault to be found with it, perhaps, is that it does not present us with details more copious; it cuts us short too often, and leaves us to desire more ample information. Respecting Germany and its institutions, in particular, we are sure most readers would be glad to have a more ample statement; for that country has of late, for various reasons (to some of which we shall presently more explicitly allude), become a centre of attraction to no inconsiderable portion of the medical profession in Great Britain.

The hospitals of Germany resemble those of France and Italy, but are inferior in point of size and internal organization: some of them are supported by government; others, as in this country, by voluntary contribution. "A fixed salary," Mr. Lee says, "is allotted to the medical men,—who are not elected by public competition, but are mostly appointed by Government." "The bodies of those who die in the German hospi-

* Observations on the Principal Medical Institutions of France, Italy, and Germany; with Notices of the Universities. By Edwin Lee, M.R.C.S. &c.

tals are generally examined, though morbid anatomy is not very zealously cultivated."

Leave we, however, for the present, the German hospitals; the universities are more to our purpose. Those of Berlin, Halle, Leipsic, Bonn, Göttingen, and Prague, are rapidly touched off by the author: we only wish he had visited more of them, that he had gone even among the minor and worse appointed establishments.

The universities of Prussia are, we believe, very well conducted—as, indeed, the whole system of national education in that country would deserve to be held up to the imitation of other continental States, especially wherever there is a government as absolute as the Prussian monarchy is. But the multiplicity of those schools called universities, both in the Prussian and other States, cannot but have a tendency to detract from their value. There are above twenty of them throughout Germany, all in a great measure independent of each other. All the other Prussian provincial establishments, however, are subordinate to the supreme school at Berlin. "The title of Doctor," says Mr. Lee, "may be obtained at any of the Prussian universities; but all candidates are obliged to repair to Berlin for the public examination, which," he adds, "is practical, rigorous, and searching."

In the Universities of Saxony, of Wirtemberg, of Austria, &c. a similar system with regard to degrees seems to prevail. But in those of Bavaria and Baden, nothing can be more lax or reprehensible.

We wish Mr. Lee had given us a full account of the state of things at Erlangen and Heidelberg. We know enough of those places, however, as *Universities*, to warrant us in reprobating them as in one respect at least disgraceful to the present state of medical respectability in Europe. Their poverty, we must presume, has much to do with influencing their will: but it can hardly excuse the rapacity with which they grasp at the bait of money—the avidity with which they carry on the traffic for what we may venture to call their miserable and worthless degrees. They sell them, it appears, on all sides: they require no personal acquaintance with their graduates; they take no count of documents of recommendation—for how can they know that they are not forged? Only send them the money in due form, and the degree comes by return of post.

That such a system as this prevails at the present day, is, we imagine, scarcely suspected by the generality of people here;—that it has been countenanced in this country, perhaps less so. There are those, however, amongst us, who know it well,—who have dabbled in it,—who have bought their honours, and wear them, too, as if they came from more respectable quarters; others, also, who have done this, but have not the courage to put on the livery for which they have so handsomely paid.

It would be amusing (were there not something of fraud and dishonesty mixed up with the transaction) to notice the masquerading of some of these Erlangen and Heidelberg Doctors among us: we could point out half a score of them at least, the names of some of whom would fill many with surprise.

What is not less remarkable, is, that some of them, too, are very conspicuous among the *reformers* of the profession: advocates for "one faculty," and for a Metropolitan Board for conferring medical degrees. That such persons should preach one doctrine and practise another, is only what is commonly observed among people of their sort: but is it fair or honest in

them to cry out so loudly for a privilege-conferring board here, when they could so easily inform their brethren how they might be accommodated quite as cheaply, and with less personal trouble, elsewhere, and while they have themselves actually been *sub rosa* enjoying the fruits of the system?

Are these worthy persons aware that they are *smugglers*—evaders of the excise—that they import goods for which, if British (and they pass them off as such) they would have a certain duty to pay? Is the government aware that there actually exists in London an *office* for carrying on this contraband trade? We should not even allude to this system of trickery, did not those who deal in it parade before the public with their foreign tinsel upon them, and wear their pinchbeck as if it was sterling gold. The fraud—the fraudulent traffic—is what deserves exposure—and exposed, so far as the *system* goes, we promise it shall be. As to the *individuals*, we let them pass, at least for the present: nor need we, perhaps, further particularize them, as their own bearing will probably give them sufficient notoriety.

What need, we ask, is there of a board in London for conferring degrees, when there is an office in the City where any body, without stirring a step from town, may, with some thirty guineas and three signatures—(who can find a difficulty in that?)—become a *bonâ fide* M.D. with the speed of an interchange of letters? If there be any doubt of this, let an epistle be sent to Dr. Fleischmann, &c. &c. of the University of Erlangen, Bavaria, to know what is to be done for a medical degree, and a prompt reply will be returned, telling the writer where *the money* is to be lodged.

Is it not "too bad" that such pranks should be played before high heaven, and sanctioned by the once reputable name of a German University? How long will the other German establishments permit such things to be done? The force of opinion put down a similar abuse which was, up to a late period, practised in this country, by some of the Scottish Universities; and shall a foreign humbug, ten times more gross, be tolerated? Here there was a possibility of at least detecting fictitious documents, should they be forwarded to Scotland; at Erlangen and Heidelberg there can be no such check. The authorities at these latter places must know—must, at least, more than suspect—that they admit to the *highest honours* of their respective Universities a number of improper characters; and we cannot excuse them when they act deliberately under such an impression.

When it was proposed by the proprietors and shareholders of the Gower-street School, that that establishment should be endowed with a privilege of conferring medical degrees, we thought it not an unfair objection on the part of the established Universities of this country, that, should such privilege be granted, the denominations should not be the same; for there were certain rights connected with the regular graduates to which surely those of the joint-stock establishment could have no claim. On the same ground, now, we totally object to those newly-created Erlangen and Heidelberg doctors mixing among us, without some badge to distinguish them from those who have graduated in an open and unexceptionable manner. We, accordingly, most strongly recommend the legislature—if they do not go the length of suppressing at once the actual traffic in sham titles, imported from Bavaria and Baden—at least that they will fix such an appellation on the new graduates of London as may prevent them from being confounded with the foreign nondescripts. If the system be pursued here much longer—and there is every likelihood of its continuance if not put a

stop to by some decided public censure —it will become imperatively necessary on all those who have legitimate degrees, to qualify them in such a manner, in their signature and announcement, as at once to secure their own claim to respectability, and to put to the blush those personages in borrowed plumes. We shall then see how the M.D. Heidel. and the M.D. Erlang. bear the light beside the M.D. Edin., M.D. Dubl., M.D. Cantab. &c. Unless some such precaution be taken, we know not how the unpleasant confusion can be avoided: only let each person be explicit as to his proper title, and then there cannot be much mistake. In conclusion, should any of our readers think us harsh, or unduly severe in the preceding remarks, we beg them to consider the nature of the evil we are called upon to expose. To those who feel *personally* in the matter, we can only say,

> "Let the galled jade wince: our withers are unwrung."

Ere we close this brief article, we cannot avoid noticing a cheat of another kind, but equally disgraceful, which has recently come to our cognizance. In a certain Royal College of the United Kingdom, which has a school of medicine attached to it, the Professor of the Practice of Physic possesses no medical degree, but stoops to the unworthy expedient of announcing himself, on all occasions, as Dr. *****,—on the strength of an LL.D. degree, which he conveniently obtained for the purpose of *appearing* duly qualified for the appointment. Those who bestowed the place knew well of the trick, but countenanced it, as we fear such shuffling and trickery are but too frequently practised in the same quarter. We are not aware that the deception has been pointed out before; and our only motive for thus briefly calling attention to it at present, is that we consider it deserving of censure of the same kind as the gross abuse above complained of.

PROFESSORSHIP OF MATERIA MEDICA IN KING'S COLLEGE.

We understand that since our former notice on this subject, Dr. Paris has been appointed Professor of Materia Medica in King's College; and we think the institution has been fortunate in securing the services of a gentleman so thoroughly qualified for the chair he is to fill. Dr. Webster, who delivered the summer course, is at present lecturing in the room of his friend Dr. Bisset Hawkins. Dr. Webster declined becoming a candidate in opposition to Dr. Paris.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 10, 1835.

HENRY EARLE, ESQ., F.R.S., PRESIDENT, IN THE CHAIR.

THIS was the first evening meeting of the season, and a large number of the Fellows and their friends attended. The appearance of the library was imposing; it is a very spacious apartment, and looks splendid when lighted up. A paper from the pen of Dr. Yelloly was read, entitled, *Observations on Vascular Appearances of Mucous and Serous Membranes, as indicative of Inflammation.* We shall give an abstract next week.

A short discussion arose respecting the views of inflammation advocated by the author of the paper. Dr. Weatherhead, Mr. Mayo, Mr. Arnott, Dr. Clendinning, and the President, briefly expressed their sentiments.

After this, the President begged leave to introduce to the notice of the meeting a short paper of his own, which was accordingly read. It related to an operation which he lately performed at St. Bartholomew's Hospital, on a patient who laboured for fourteen months under a formidable tumor over the scapula. Opinions had been strongly expressed against the propriety of meddling with it, on the supposition that it was malignant; but the result was highly successful, and proved the correctness of Mr. Earle's views.

Before the meeting broke up, the President, in a short address, urged the Fellows to bring forward their papers as early as they could, and not to leave them over, as they generally do, till the latter part of the session. He congratulated the Society on the accession they were about to receive to their numbers, several candidates for admission to the Fellowship having been proposed in the course of the evening.

CLINICAL LECTURE

ON

DISEASES OF THE SPINE,

Delivered, Nov. 3, at the Middlesex Hospital School,

By Sir Charles Bell.

Remarks on the present System of Medical Education—Diseases of the Spine—Lateral Curvature—Curvature with Caries—Scrofulous Inflammation.

Gentlemen,—We have reason to regret that you are so driven from one lecture to another, and without interval or repose, from daylight till night. In these circumstances it is hardly possible for a youth, though possessed of the most ingenuous and happy disposition, to become a diligent student.

We owe the regulations under which we are bound to the Company of Apothecaries, and the criminal neglect of the two Colleges. The evil is twofold: the mind of the student is dissipated, and the office of the lecturer is degraded. It has always appeared to me, and is, I believe, acquiesced in by all educated people, that the student should hold his teachers in respect, that their place should be considered honourable, and that that, too, should be gained by the successful pursuit of the very studies they are inculcating to their pupils. The present system overturns all this. The course of my duties, as well as your course of study, is directed at the Apothecaries' Hall of London.

To whom, then, am I to bid you look as the heads of your profession, as showing you examples of devotion to science, and to whom, indeed, you ought to be directed by the respect and gratitude of mankind? I pretend not to say who is to blame. These changes commenced in Parliament, through the philanthropy of the moment, to prevent the lieges being poisoned. If I should be so unfortunate as to stand in opinion against Colleges and Parliament, I must from time to time call upon you to remember for what purpose you are here in London. Your long list of certificates you must have; but I conjure you to act as if anatomy, and such uses of anatomy as you see in hospital practice, were the business of your life in London, and not to be satisfied with learning to answer such questions as may be put to you at any board. Look upon the opportunities offered to you, as leading hereafter to the decision of matters of life and death.

What has been said of books is more applicable to lectures. A great English philosopher said of his adversaries—"If I read as much as others, I should be as ignorant as they were. The meditation on a few good works is more profitable to the understanding than an abundant draught of indiscriminate learning."

But let me turn to our present duties. I have requested you to come into the theatre rather than your room in the hospital, that I might show you these preparations in connexion with the cases you have seen. And now observe the advantage of giving clinical remarks to those to whom I know the right elements have been taught, instead of addressing gentlemen from three or four neighbouring schools, who have in all likelihood no ideas in common with me.

I will furnish you with an example how easy it is to give such lectures to those who have been initiated in the principles. If you go into Percy ward you will there find a man lying with a wandering and bewildered eye, with a very very pale face, and spasmodic twitching of the eye ball. There is a deep-coloured extravasation of blood around the eyes, with grumous blood, or brown serum, passing from his ears. This man has fallen upon the vertex of his head; and were I to enter upon the consideration of the case with those who had not gone through the demonstration of the bones of the cranium with us, you know full well that I should be obliged to enter upon the whole structure of the skull, and the mechanical principles on which it is built. But now, with one word, one half sentence, I can say to you there is the example of which I have been speaking. Here a blow has been inflicted upon the upper part of the parietal bone, and you see the effect upon the temporal bone, and upon the ear. Here is a man lying with a fissure in the base of the skull from a blow on the superior convexity. It is not requisite that I should go into the whole proof, and repeat the demonstrations; I have merely to say, that this is an illustration of the principles I formerly established*. Or, supposing that I have to point out to your notice another case, where the humerus is fractured near the head, I have hardly occasion to speak to you of the necessity of particular appliances to counteract that condition of the parts when, by the division of the bone, the adjustment between the pectoral

---

* This man has since died. A rent was discovered passing across the base of the skull through both temporal bones, and the orbital plates were broken. There was ecchymosis of the scalp, and the brain had blood effused in its texture, near the vertex; but there was no fracture of the bone at this part. Purulent matter was found in the lateral sinuses.

muscle, the latissimus dorsi, and deltoid, is lost.

After this preface, I beg your attention to *Diseases of the Spine*. First, we have a case of what is termed lateral curvature. Secondly, there is a case of curvature of the spine connected with caries of the bodies of the vertebræ. Thirdly, there is a case of inflammation and scrofulous disease going on in the top of the spine, near the occiput. Fourthly, there is a case of irritation and spasmodic affection of the sterno-cleido-mastoideus, affecting the vertebra in a secondary way. There is next, fifthly, a case of permanent rigidity of the sterno-cleido-mastoideus, and distortion of the head and shoulder. These cases are at once under your eye in Seymour ward; and there cannot be a subject better suited for your especial notice than this.

Would that our philanthropic meddlers, who set you to study botany within the sound of Bow bell, knew the hundredth part of the miseries inflicted on this class of patients through ignorance, and the tricks of cold-hearted and selfish quacks, who will boldly undertake to reduce bones, such as you see here distorted by formidable internal disease, accusing you regular surgeons of incapacity and timidity.

The least of these errors, and one of daily occurrence—now I speak to your hearts—is the ordering a young lady, of delicate frame, with nervous and sympathetic pain in the back, to lie during eight and sixteen months in the horizontal position; one who is nervous, low, and spiritless, whom to keep in health requires all your means, and most of all stands in need of bodily exertion and change of scene.

LATERAL CURVATURE OF THE SPINE.

I shall take advantage of the dresser's book to read the cases written down. The first case is that of Eliza Milras, admitted so far back as July 23. There is here no case written out; but I have repeatedly pointed out what are the circumstances which characterise the condition of the spine in this young woman. Here is a young girl, and girls are chiefly subject to this lateral distortion of the spine, in whom you discover these marks: first, the parents of the patient notice an awkward gait as she walks across the room, especially if she be on ceremony, and they then observe that the right shoulder is *out*, and that the dress falls from the left shoulder. When you loosen the clothes, and expose the back; you find that the right shoulder is prominent, that the scapula is elevated; that the cause of the elevation is a large protuberance of the ribs, and not any affection of the scapula; that the shoulder is not in fault, but that the ribs, by spreading wide, and by their gibbosity, have thrown up the shoulder-blade. On the left side, and upper part of the thorax, the ribs are huddled together, and consequently depressed, and the scapula also. You find that the expansion of the ribs on the right side is owing to a curvature of the spine, the convexity of which is to the right; that there is a second curvature below, giving the spine the shape of the Italic *S*. You may trace the same characters in the reverse direction, as they progressively present themselves; that is, you find that the distortion occurs in an indolent girl, weak, with her constitution disturbed by the first occurrence of uterine irritation. She has pain in the back, great weakness, languor; and with this debility she *hangs*, as they express it in the north, upon one foot—upon the right foot. The consequence of that is the relief of the left extremity, and the inclination of the lowest part of the spine to the right side, with a slight spiral twist. When the spine is thus twisted to the right side by a habit of standing, the whole body would be thrown to that side, were it not steadied and poised by a second curve, such as you see here [shewing the specimen.] It is the second curve which throws out the ribs to the right. You see [still regarding the skeleton] the spine first inclined to the left side, and then inclining to the opposite side; and now you perceive that the great convexity being towards the right side, and the concavity towards the left, the left ribs are drawn together, and consequently the whole extent of the thorax is here diminished.

We shall not speak of the distortion of the fore part of the thorax, or of the appearance produced on the mamma. The ribs on the right are expanded, and consequently the convexity is increased; hence the scapula, lodging upon them, stands higher than the other; and thus we see the reason why the right shoulder is thrust out, and generally higher. You also observe the reason why there is an inequality in the pelvis, and why the mother or the governess first notices the thrusting out of the ala ilii. I mention this kind of distortion by way of contrast to what is to follow. It is a mere defect of a poor constitution,—of the constitution disordered and irritated by the first arrival of the period of constitutional change in the female; and most of all, is induced or promoted by indolence—by a want of that activity which I need not state to you is the great source of perfection of structure. That spine [presenting a preparation] is thus distorted; and you have an opportu-

nity of comparing it with all those other specimens before me where the deformity is a consequence of disease. The spine consists not only of bones, but of cartilages, ligaments, and numerous minute muscles, going from point to point; and you will recollect that I took the opportunity of stating that the bones did not grow by themselves, nor did the cartilages, ligaments, or muscles, but that they all belonged to one constitution, and failed or became perfect together; therefore it is quite superfluous for any person to talk of the affection being in the muscles, ligaments, or bones, each separately. The whole texture of the spine is weakened, and it is principally owing to that want of freedom of action which is its stimulus to perfection. The principle of cure, therefore, must be activity, which activity must be at first gentle, and may be directed so as to counteract the curves. But you must recollect that you do not bend the spine as you would straighten a crooked stick; you must direct its growth aright. And to be effectual and permanent in your cure, your means must be long pursued.

What these are, you have in part seen in the treatment of this patient.

SCROFULOUS CARIES OF THE VERTEBRÆ.

Let us now take up another case. "Ann Hatchies, 20 years of age, was admitted on the 9th of September. She states that about a year and a half ago she was subject to pain and weakness in the loins, and a general weakness of the whole body; that about two months after this she lost the use of her lower extremities; soon afterwards she was admitted into the Salisbury Infirmary. She continued there six weeks, during which time various remedies were administered, and issues were applied on each side of the affected part of the back, but without affording any relief. She says that she knows not how to account for her illness, unless it be that she had been accustomed to lift heavy weights. At present there is very little pain any where; she feels comparatively easy when in the recumbent posture, but when made to sit up she experiences a sense of weight and weakness in the back. Her lower extremities have lost all voluntary motion, but sensation is not entirely gone. At one time she had great difficulty in passing her urine, but now that symptom is much relieved. On examining the back, there is a projection backwards of some of the last dorsal vertebræ. The catamenia appeared when she was first affected, and have not been seen since. Her general appearance is that of a person in health. When the extremities are touched, they move, though without her knowledge. There is no relaxation of the abdominal muscles. She feels when the foot is cold, or when cold is applied to the extremities."

Here you have a case which presents before you, in a few sentences, the character of scrofulous caries of the vertebræ, or the *acute curve* of the vertebræ; and the first thing that you mark in this narrative is the formidable contrast it presents to the last. Again, I refer to what I said of the bones, that the bodies of the vertebræ themselves are spongy and light; and that in proportion to the spongy character of bones, are they subject to scrofulous inflammation. There is some little debate among pathologists as to whether the disease begins in the ligaments, the intervertebral substance, or the body of the vertebra. If we refer to dissections, we find that all are affected; and it is an idle speculation to endeavour to determine which is primarily attacked. We know that the bones, the ligaments, and the cartilages, are parts of the body most liable to scrofulous action; and in the spine they are most intricately combined. In the case, it is said that there was a wrench, or at least that the patient was obliged to raise heavy weights. Now it is very possible that the spine may have received on some such occasion a slight injury. I do not quite agree with my friend, that the girl appears to be healthy; for I should say, on the contrary, that she has a most distinct scrofulous diathesis marked in her appearance.

Now, gentlemen, you perceive the advantage of a school. Here is a case nothing at all like the last; and I put into your hands [referring to a specimen] a spine with an acute projection directly backwards, that you may contrast it with the former specimen. The projection in the back is formed, as you see, by the wasting, ulceration, and absorption of certain of the bodies of the vertebræ.

When you have these facts before you, I need hardly point out to you what will be the great questions of practice.

But first as to what is said of sensibility remaining, whilst motion is quite gone. There are some points in the structure of the spinal marrow, and the situation of the disease, that may relieve our perplexity on this head. You remember the character of the spinal marrow, and that the roots of the nerves of motion lie along it on the surface, next to the bodies of the vertebræ, while the roots of the nerves of sensation are on the posterior surface. Again, if you remember the manner in which the ligamentum denticulatum runs down on each side of the spinal marrow to connect it with its sheath, you will at

once perceive that there is a sort of septum—imperfect certainly—but a sort of partition, between the anterior and posterior surfaces of the spinal marrow. It certainly is not correct to state that it is the curvature of the spine which, causing the bones to press upon the marrow, produces paralysis. In fact, the paralysis precedes the sinking of the spine, and often disappears when the curvature is at the utmost. It is the inflammation of the bones which disturbs the function of the spinal marrow. If inflammation, therefore, takes place in the bodies of the vertebræ, it must affect the motor nerves earlier, and to a greater extent, than the nerves of sensation. We observe the fact in this case, and this is the explanation that I put upon it.

You are aware that there are people in town who pretend to restore the shape in this curvature or "dislocation" of the spine, and who ridicule the regular surgeon for not attempting and effecting the cure of this scrofulous caries of the vertebræ. They recommend the raising of the body, or the stretching of the spine by instruments. It comes, therefore, to be a very important question to you, what you should do in these cases. You may deceive yourselves, or you may deceive the friends, by extending the patient some inches, and you may support your patient in this dangerous position by an iron case; but what are you actually doing: you are raising one diseased surface of the vertebræ from the other. I repeat to you that inflammation loosens the textures of the ligaments, and when the ligamentous connexions are thus destroyed, and there is actual caries consuming one or two of the vertebræ, if you raise the spine, you rend the soft union of the inflamed bones, and make a gap between their surfaces, by the union of which it is that we hope for improvement and cure. It is to anchylosis that you must look for the most favourable issue; and unless the parts be kept perfectly at rest, and unless they be kept together, how in the world can we expect anchylosis to take place? Besides, there is great danger in thus drawing the diseased bones separate; for you will observe, that although there is a gap in the bones, there is still a soft ligamentous union, and this will be torn. There is another thing to fear, and that is the sudden falling down of the spine when it is thus raised. I look with horror upon the effect of a sudden fall when the bones are thus held apart by mechanical means. Such an accident would cause a sudden curve or check of the spinal marrow itself. What does this quackery mean? It is doing fatal injury if the disease has not proceeded to anchylosis. But if anchylosis has taken place, may good be obtained by this stretching, or twisting, and moulding? Be assured that all that can be performed is by causing the healthy part of the spine above and below the anchylosis to accommodate to the permanent curve, and be made somewhat straighter: a real advantage, you will say; true, but at great hazard to the part originally diseased. The quack accomplishes this at the risk of breaking up the bony connexion, or tearing asunder those connexions which are not yet bone, but only ligament, and thus exciting inflammation. You see, then, what must be the condition of cure—that the patient must be kept in perfect rest.

Look round the hospital, and you will see hundreds of instances—I do not, I am sure, exceed the number—hundreds of instances where motion is keeping up disease. It is so with all the joints, it is so with all the ulcers which give you so much trouble, and so it is here. As long as a person moves about, and twists and turns,—for you are aware that there can be no change of the extremities without a corresponding change of the centre—so long there is an incessant source of irritation. It is your business, then, to keep the patient in the horizontal posture, to have the mattress moulded so that the projection of the spine can sink into it without injury, and the sides so guarded that if the patient moves up at all there may be no motion in the inflamed parts.

Then comes the proposal of counter-irritation. Some surgeons say that this does no good; yet I have been loath to allow this. You may adopt counter-irritation by issues; but issues and setons are to be omitted when a fever of irritation is kept up in the patient's constitution, for as the remote origin of the whole is in the constitution, you must endeavour to rally its powers.

I would make just one remark more, because I see it stated in a book which, I believe, is a good deal read by the class of students, that there is no disease which presents itself in so great a variety of forms as this. This seems to be very extraordinary; but I think I know how this opinion arises; it is by mistaking the disease. When there is caries of the vertebræ—when there is an actual falling forward of the spine—the symptoms may vary, inasmuch as the inflammation may reach to the spinal marrow or it may not; it may be attended with more or less pain, with more or less paralysis; but I hold that the case is ever obvious in its symptoms. Nevertheless, it must be admitted

that there is nothing more difficult to distinguish than the different affections of the back and loins. The practitioner is continually falling into mistakes. A languid girl, of fifteen, complains of pain in the loins, and inability to walk or sit long. On the spine being examined, she starts away when a particular process is pressed. Here is the source of error; girls with no actual disease shrink and complain when certain spines are touched, and if you implicitly trust to this you may be misled. Now you say, "Do not deceive yourself; are you sure there is pain?"—and you try again. Still there is distinct pain; but in this we must not put confidence; and, by a little further examination, we find there is another painful part, remote from the first, and which, on being pressed, gives the same sensation. These are hysterical and nervous pains. Another source of mistake is in the pains symptomatic of internal disorder; as of the colon, kidney, or uterus or ovarium.

If a weak hysterical girl be, in these circumstances, laid on the horizontal plane,—confined necessarily to her room—disappointed of all variety, all amusement, and the muscles unexercised for a great length of time—what effect, according to the principle I formerly laid down, is to be expected, and what hope of a rally of the constitutional powers?

If I have raised one, I have raised twenty young women out of this condition alone; some of them having been from eight to sixteen months in the horizontal posture without any disease of the spine at all, but merely suffering from a sympathetic pain which arises from an internal disorder.

DISEASE OF THE UPPER VERTEBRÆ OF THE NECK.

I will now take the case of "Mary Blainer, 16 years of age, admitted on the 15th of October, on account of a distortion of the head upon the neck, or displacement of the upper vertebræ of the neck, which throws her head to the left shoulder. There is a swelling extending from the occiput, five fingers' breadth, down the neck. The third and fourth vertebræ project, but they are obscurely felt, as an inflammatory hardness surrounds the bones, and occupies all the upper and back part of the neck. She cannot turn her head without pain, and the chief motion is about the fifth vertebra of the neck;" that is to say, if she attempts to move the head, the spine yields only about the fifth vertebra of the neck, and all the upper part is an inflexible mass. Here is a preparation shewing what may take place in these upper cervical vertebræ, and renders it probable that such a soldering is in our patient now progressive. As a proof of what extraordinary defects may arise in the upper vertebræ, I shew you another preparation. There are two spinal canals, as it appears, and what could have come of the spinal marrow at the time the atlas and dentata were so strangely displaced? [The lecturer here held in his hand a remarkable specimen of fracture of the atlas and of the dentata, with displacement of the fragments: the anterior half of the atlas was united, by its two broken extremities, to the fore part of the dentata, and thus presented the appearance of two foramina for the spinal marrow in one bone]. In this patient, however, the chief motion is about the fifth vertebra of the neck. The case goes on to state, that "in the summer she had rheumatic fever, which continued for four months. On getting better of the fever, this swelling began. It is observed that she has no weakness of the arms or fingers, and never had. She has, however, been subject to a difficulty of swallowing sometimes:" but she says she has had no experience of this for some time. She herself attributes this difficulty of swallowing to a tumor which took place in the anterior part of the throat. There are two caustic issues in the neck, and she has taken iodine and liq. potassæ. Her head is more upright than when she came into the house."

The orders of the surgeon to support the neck by a collar, which shall reach from the shoulders to the ears, have not yet been executed.

The first reflection which I make upon this case is prompted by the long continued rheumatic fever; for in entering into these cases you find, for the most part, that the disease is preceded by long-continued fevers or suffering, measles, small-pox, scarlatina, &c. Confinement and general languor will produce a scrofulous diathesis, and a course of mercury, for whatever object pursued, will have the same effect; indeed, whatever reduces the constitution will induce a disposition which subjects the person to scrofulous inflammation from a slight sprain of these ligamentous parts.

I dare say this case must appear more formidable to you than the former. Inflammation in the spinal marrow is bad enough, but inflammation or pressure on the medulla oblongata must, you know well, produce instant death. We have had in the hospital some such cases of sudden death by fracture of the spine and occipital bone, and also by the giving way of the ligaments of the upper vertebræ. It is terrifying to think

of the perilous brink on which a girl in this condition stands unconsciously. You have been but lately informed how bone and ligament participate in scrofulous inflammation; and that when the ligament is inflamed, it becomes loose and weak in texture. When, therefore, we see a mass of inflammation around the atlas and dentata, must we not be apprehensive for the state of the ligaments which support the head in connexion with the vertebræ? A slight wrench might tear these ligaments in their weakened condition; and on the displacement of the vertebræ the medulla oblongata would be nipped, and in an instant, death would follow; for if there be pressure at that part, it being the origin of all the nerves of respiration, there is not a word spoken or a breath drawn, but death is instantaneous, as when an animal has been pithed.

Seeing that instant death would be the consequence of an injury to this part of the spinal marrow, we cannot avoid being alarmed at seeing such a mass of disease around the upper part of the spine. It is pretty obvious, at the same time, that this case resembles what is called the poll-evil in the horse. There are ligaments connecting the horse's head to the neck, and bursæ, which are under the great suspending elastic ligament; these ligaments and bursæ suffer when the horse is reined up suddenly, the reins and bit operating through the length of the head, as by a long lever, on the joint of the occiput. We cannot be surprised that the sudden pulling up of a horse should produce sprain, and injury, and inflammation, suppuration, and sinuses here. I apprehend that there is something of the same kind in this case, set up by a wrench, and that the disease may thus be happily external to the bones and theca. You remember how thick the theca is here, and the ligamentum infundibuliforme, that powerful ligament which runs down into the spinal canal from the dura mater, on the inside of the occiput, like a funnel. That, I verily believe, may prove to be the protection to the medulla in the present case, and which allows the girl to go about fearlessly at the moment that I am full of apprehension.

As to the cure, it must be effected by attention to the constant fixing of the part, by supporting the head, and preventing all lateral motion, and inculcating the necessity of avoiding all violence; and then time will solder these parts together, as it were, or, in a more accurate way of speaking, produce anchylosis; and the girl will be safe as to life, but, of course, she must lose all the easy motion of the head on the neck, which can only be imperfectly substituted by the additional motion of the lower part of the vertebræ of the neck.

All this is but preparatory to a case which I believe will interest you still more; it is that of a poor woman who has got an affection of the sterno cleido-mastoideus; it is a curious disease, of which I have seen a great deal. This, again, will lead to another case, in which there is a permanent rigidity of that muscle. We shall take these up on a future day, and then go into another ward, where I see some interesting cases of disease of the nerves of the face, which will follow very naturally afterwards.

ST. GEORGE'S HOSPITAL.

CASES, WITH CLINICAL REMARKS.

Articular Rheumatism—Chorea—Conversions of Disease—Balsams in Chronic Bronchitis.

The following case is a very good example of the effect of colchicum in simple inflammation of the joints. It was this power which caused colchicum to be called "theriaca articulorum."

Jane Reeves, æt. 28, was admitted into St. George's Hospital, under the care of Dr. Seymour, September 16, 1835, for rheumatism; which was confined to the joints and bursæ. Her complaints were of three months' duration, and the elbow and wrist-joint of the left hand, and the joint of the metacarpal bone, with the index finger, were painful, swollen, red, and there was distinct fluctuation present. The pulse was quick and feeble; the catamenia regular; bowels open. She was ordered

> Vini Radicis Colchic. ℥ss; Magnes. Ustæ, ℈ss.; Mist. Camph. ℥x. M. haustus ter die sumend.

> ℞ Extract. Aceti Colchici, gr. iij.; Pulv. Ipecac. C. gr. v. M. Ft. Pilulæ, ij. æquales mane et vespere sumend.

On the 20th, four days after admission, all pain, swelling, redness, and tension of the affected parts, had disappeared, and the patient laboured under the constitutional affection produced in some individuals by colchicum. She had frequent vomitings, some sensation of syncope, and general distress. The vinum colchici was intermitted, but the pills were continued, in order to prevent a return of the complaint, and she was ordered the following diffusible stimulant:—

℞ Sp. Ammon. Succin. ♏xv.; Mist. Camphoræ, ℥iss. M. haustus bis in die sumend.

On the 30th, the swelling, effusion, and pain, again appeared in the index finger-joint, and also (in a less degree) in the wrist, and was attended with much pain.

The use of the wine of the colchicum was resumed as before.

In four days the whole of the symptoms had again disappeared, but she was retained in the hospital upwards of a fortnight, that no doubt might be entertained of her recovery, when she was dismissed quite well.

Dr. Seymour remarked, in his clinical lecture, that although the vinum colchici had appeared to be the most effectual preparation in the present case, it was by no means certain that this would be the case in other examples; that he had seen cases in which it had failed, and the acetous extracts been very effectual; and again, cases in which both had failed, and the inspissated juice (succus spissatus colchici) had cured severe forms of the disease. Thus, not only was the remedy itself almost proverbially uncertain, but the preparations were also liable to great variation; the vinous tincture agreeing best with some, the extracts best with others; and that therefore we ought not to suppose colchicum to have failed after having employed fruitlessly one of the preparations.

The following case also, in its courses, shows at least the auxiliary advantage of colchicum over effusion into the joints, accompanied by acute pain. The case is also remarkable on other accounts, presenting the rapid transition of one disease to another, which has been so well described in the late Dr. Ferriar's paper on the Conversion of Diseases.

Maria Lum, æt. 14, was admitted into St. George's Hospital, under the care of Dr. Seymour, August 19, 1835. The patient was much reduced by indigence and illness. She was thin, weak, pale, and affected by a constant irregular action of the voluntary muscles, so as to constitute an aggravated case of chorea sancti viti. She articulated with difficulty, owing to the spasmodic protrusion of the tongue; and her pale, unhealthy, emaciated appearance, was very striking. She had suffered, it was reported, from rheumatism. Her bowels were confined; catamenia *nondum apparuére*; pulse feeble and small; no heat of skin; tongue clean. The patient was purged, and then put on a course of medicine which experience has shewn to be most effectual in similar cases—the preparations of steel, with purgatives. She was ordered

T. Ferri Ammon. ʒj.; Ammon. Subcarb. gr. iij.; Mist. Camph. ℥ij. st. haust. b. d. sumend.

℞ Pil. Aloes c. Myrrh, gr. viij.; Ft. Pilulæ, ij. alternis noctibus sumend.

She was ordered milk diet, and subsequently ordinary diet (four ounces of roast meat daily).

On the 26th, little amelioration having occurred, she was ordered, instead of her draught,

Mist. Ferri C. ℥j. b. d. and the use of the shower-bath.

Some advantage appeared to be derived from this plan; still she became occasionally worse; and, on the 17th of September, the preparation of steel was changed to the subcarbon ferri; ℈j. of which was taken three times daily.

On the 23d Sept. a very remarkable change had taken place; the patient was comatose, the pulse extremely quick and feeble, the pupils dilated, and the head rolled back, as in cases of organic disease of the brain. She was insensible to external stimuli; the urine scanty, with occasional rigid spasms of the lower extremities. Dr. Seymour entertained no doubt of effusion existing in the brain; he ordered as follows:—

Abrad. Capellities. Applic. Emplast. Cantharid. capiti raso, et exhibeat Ung. Hydrarg. parti vesicatæ.

25th.—The spasms of the extremities much less frequent. Pulse quick and small, irregular; skin hot; still senseless; urine scanty.

℞ Tinct. Cantharidis, ♏xxx.; Infus. Digitalis, ʒiij.; Aq. Menth. Pip. ℥x. M. ft. haustus ter die sumend.

29th.—A considerable discharge of urine has occurred; answers questions indistinctly. Pulse 110, very weak, but regular.—P.

On the 3d of October she was sensible, answered questions rationally, and the involuntary spasms of the muscles, so severe at the commencement of her illness, had nearly ceased. The urine continued to be abundant; she complained of some pain on the right side of the head.

Applic. Hirudines vj. pone aurem dextram.

On the 12th the leeches were repeated, from a return of pain.

She continued the diuretic mixture until the 12th October, when it was omitted. The spasms of the voluntary muscles had entirely ceased.

On the 21st a new set of symptoms presented themselves. The right hip and knee were much swollen, tense, full of fluid, but without redness; and the pain was so intense that she could not move the limb without screaming, nor bear it to be touched without suffering as severe pain as in disease of the hip-joint. Pulse 120, but without greatly increased heat of skin; bowels open. She was ordered—

Vini Colchici, ♏xx.; Magnes. Ustæ, gr. x.; Mist. Camph. ℥x. M. ft. haust. ter in die sumend.

℞ Subm. Hydr. gr. iij.; Opii, gr. ½. Ft. pilula alternis noctibus sumend.

22d.—Moves the leg more easily, and with less pain. Pulse 110; skin warm. —P.

24th.—Pain in hip and knee very greatly relieved; some effusion into the wrist-joint and bursæ of the left hand. No pain of head.

27th.—There were no remains of effusion, or swelling, or pain, in any of the joints. Some sickness from the colchicum. Bowels open.

Inter. omnia.

Since this time the patient has gained strength; no symptom remains of any of her complaints.

It has often been observed, that in the rare instances of metastasis of rheumatism to the brain, it has been when the disease has affected the joints and bursæ. In this instance there appeared to be a connexion between the effusion into the brain and effusion in the joints.

The following is an example of an aggravated case of chronic bronchitis, cured by the employment of the balsams, once so much used in the treatment of pulmonary consumption, and which fell into oblivion after the pamphlet of Dr. Fothergill, but which are so much recommended by analogy with the fluxes of other mucous membranes:—

William Lloyd, æt. 18, was admitted with the following symptoms:—Cough, with frequent puriform expectoration of a greenish colour, and very adhesive. Pulse 90; tongue furred; dyspnœa; impossibility of lying down in bed. Bowels costive; urine scanty and high-coloured; no dropsy. Has been addicted to drinking; is much emaciated; attributes his complaints to cold.

℞ Balsami Peruviani, ʒj.; Mucilag. G. Acaciæ, ʒij.; Syrupi Papav. Alb. ʒj.; Mist. Amygdalæ, ℥x. M. ft. haustus ter die sumend.

12th.—He was ordered to be purged more briskly with calomel, followed by H. sennæ, and then to resume the use of the Peruvian balsam.

19th.—Expectoration was reported to be diminished. Pulse 100. Sleepless nights from coughing.

Acet. Morphiæ, gr. ½; Oxymell. Simplicis, ʒij.; Aq. Fontanæ, ℥x. Ft. haustus h. s. s. Fish diet.

23d.—Expectoration diminished; lies down in bed, and on either side, without difficulty.

29th.—A pint of porter was added to the ordinary diet (℥iv. of meat), it being remembered that he had been in the habit many years of drinking hard.

The expectoration went on now gradually diminishing. When admitted he expectorated more than *a pint* daily, of green, viscid, puriform matter, without any apparent admixture of saliva, such as is seen when pneumonia is ceasing under appropriate remedies, or, as in this case, in old and very extensive chronic inflammation of the mucous membrane of the bronchi.

Dr. Seymour stated in his clinical lecture, that he had seen most striking cases of recovery, even where hectic fever and great emaciation were present, from the use of this medicine, which appears to act much in the same way as balsam copaibæ, or the turpentines, act in inflammation of the mucous membrane of the urethra.

CONDUCT OF THE NEW POOR LAW FUNCTIONARIES TOWARDS THE MEDICAL PROFESSION.

TREATMENT OF THE SICK POOR—SUGGESTIONS TOWARDS A REMEDY.

To the Editor of the Medical Gazette.

SIR,

THE favourable notice which you have bestowed on my letter, published in the *Times*, induces me to trouble you with some further remarks on the subject. Indeed, at a time when not only the sick poor and the country practitioners are driven to *feel*, but the gentry and clergy of the rural districts are compelled to *see*, the urgent necessity for some alteration in the provisions for parochial medical relief, there cannot, I imagine, be too ample an investigation, or too free a discussion, either of the evils alleged to exist, or of the remedies needed.

It is really a matter hedged round with difficulties. *Pauperism* is always an unwelcome topic; and never more so than when it wears the garb of *sickness and disease.* It therefore requires an effort, and a *strong* one, to induce the community to pay that attention to it which humanity and right reason dictate.

That it has hitherto been grossly neglected by *all* parties, is a sad truism; and particularly that the framers and functionaries of the Poor Law Amendment Act have blinked and slighted it, is but too plain.

If, however, the skilful medical treatment of *more than* 1,000,000 (! !) cases of sickness, occurring annually in the pauper population of this country, be worth consideration, it is surely not too much to expect that the legislature should interfere to provide in future proper attention to the wants of these numerous sufferers.

The Poor Law Commissioners, indeed, seem to be peculiarly unfitted for giving accurate and liberal consideration to the subject. Holding their offices on the "*expressed or implied condition* *" of saving to the greatest possible extent any expenditure on the wants of the poor, it is not surprising that they should act wisely only in those sections of their labours where the connexion between *extravagance of outlay* and *aggravation of pauperism* is proved manifestly to exist. It would be expecting that they should possess the eyes of Argus, or the two faces of Janus, to suppose that, while watching with jealous intentness every penny bestowed on the wretched paupers, they should discover some circumstances where an increase of expenditure might not only be *just* to the sufferers, but *ultimately beneficial* to the community.

And even to lay aside an *à priori* supposition, it is quite sufficient to look at the arguments of these gentlemen, on medical relief, contained in their last Report, and in the itinerant declamations of Sir F. Head, Mr. Gilbert, Mr. Mott, and (*proh pudor!*) *Dr*. Kay, &c. &c., to find that they are utterly incapable of taking an enlarged and philanthropic view of the subject.

The "Parish Doctor," exposed to the summer's sun and winter's blast, toiling by night and day, on a pittance that a foot-boy would spurn, appears to be as fair an object of their animadversion (and, I regret to say, unwarrantable vituperation), as the overseer who was accustomed to pay his own bills from the rates, or the able-bodied impostor, who bullied the frightened farmer into a handsome weekly allowance for doing nothing.

I am not, therefore, unreasonable in asserting, that, to organize satisfactorily pauper medical attendance, it is absolutely necessary that *parliament should interfere*; and, to suggest the leading particulars for legislation in this matter, is my present object in writing to you.

The evils mentioned in my former letter will readily direct the minds of the readers to some alterations, but the *modus* by which the improvement is to be effected, with a *due regard* to the working of the present measures for diminishing pauperism, requires more careful consideration.

It appears to me, firstly, that a *fixed* remuneration for the medical officers of parishes is necessary: without this, the evils of "tender" must continue, and the unworthy avarice of one party, with the infatuated speculation of the other, must remain unchecked.

Secondly, *the remuneration so fixed* must be calculated for *each parish separately*; otherwise the shameful monopoly of numerous parishes by one medical man will still flourish.

Thirdly, the sum paid by each parish must be made to vary with the variation of pauperism; and if (according to the hopes of the country) the burden of poor-rates should gradually become a trifling one, so must the medical salary adapt itself to the reduction.

Fourthly, this salary must be in proportion to the labour of the medical attendant in each parish; and this will, of course, depend, 1st, on the *distance* of the parish from his residence, and 2dly, on the *number* or *density* of the population of the parish.

The item of *distance* in the calculation, is, indeed, a most important one; without it, there would be no limit to the appointment of surgeons residing at a great distance from their poor patients, and no pecuniary check to depriving the sick of that speedy and easily-obtained assistance so necessary for their well-doing.

Fifthly, the remuneration should be such as will *defray the cost of a proper supply of medicines*, &c. &c. and will also afford a moderate surplus proportioned to the exertions of the attendant.

Such are the principles on which a scale for the salaries of parochial surgeons should be calculated, nor do I think the calculation would be a difficult one: there are sufficient data to act upon, and I hope that the Committee to which you allude, in your leading article, will propose one satisfactory both to the profession and the public. *Otherwise* government might appoint a commission, composed of an equal number of *laymen* and *professional* men, to compile a fair and equitable calculation for these payments.

That the above plan would remove many of the evils connected with the pre-

* Vide Report of the Commissioners on Medical Relief, August 1835.

sent system, will hardly be denied; but there are *other evils*, for which *other remedies* must be provided. As I have already occupied, I fear, an undue space in your journal, I will, with your permission, defer the consideration of *these* till the next week. In the meantime,

I remain, sir,
Your obedient servant,
RURICOLA.

COLLEGE OF SURGEONS.

LIST OF GENTLEMEN WHO RECEIVED DIPLOMAS IN OCTOBER, 1835.

Arthur Philbott, Hookey, Wells.
Samuel Radcliffe, Leeds.
Edman Scott, Wallington, Oxon.
Adolphus Barnett, Commercial Road.
George Newman, Glastonbury.
Samuel Lees, Ashton-under-Line.
George J. M. Wilson, Greenhithe.
John Paterson, Aberdeen.
Charles Upton, Chapel-street, Grosvenor Place.
Edward S. Cuming, London.
Harold Giles, Margate.
Douglas Dutton, Upper York-street.
George W. Bore, Isle of Wight.
Campbell G. De Morgan, Upper Gower-street.
Wm. P. H. Eales, Kingsbridge, Devon.
Benjamin K. Brydges, London.
Arthur Brebner, Jamaica.
George Cooper, London.
William Rose, Wicklam, Bucks.
John Tallon, Dundalk.
Charles Carruthers, Holbeach.
Zechariah Lindo, Bishopsgate-street.
James H. Shirreff, Deptford.
Thomas Wilson, Congleton.
Charles Draper, Kenilworth.
David Prothero, Llandiloes.
Jas. Gilbert, Norfolk-street, Middlesex Hospital.
Simeon W. Hardy, Cork.
Peter Scott, Dundalk.
Noble Seward, Limerick.
C. W. F. Hunter, Kinsale, Cork.
Samuel Marshall, Marnham, Notts.
John Chippendale, London.
W. B. Carpenter, Bristol.
Walter C. Poole, Yanghall, Cork.
John Swan, Castle Durrow, Kilkenny.
Arthur Scott, Canada.
Andrew Durham, E. I.
John C. Tice.
John Friend, Rainham, Kent.
F. P. Pascoe, Penzance.
John R. Philipps, Aberystwith.
John A. Field, Milford.
Henry C. Walton, Dundrap, Dublin.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

October 29, November 5 and 12, 1835.

Edwin Bennett, Manchester.
James Carter, Witham, Essex.
James Gibson, Hull.
Joseph Frederick Handley, Chipping Norton.
Fredereck Le Mesurier, Guernsey.
John Nigel Heathcote, Newcastle.
William Tarleton, Henley in Arden.
F. W. Willsford, Chelsea.
Joseph Simons, Ullesthorpe.
William Bisdon, Dolton, Devon.
Theophilus Goate Gurdon, Hadleigh, Suffolk.
William Roley Lomas, Belper.
William Lord, Farringdon, Berks.
John Daniel Alty, Ormskirk.
Robert Bacon, North Walsham.
Henry Merford, Bath.
William Berwick Clarke, Beekermoat.
Peter T. Kempson, Birmingham.
William Sheldon Sweeting, Bridport.
John James Mason, Cheltenham.
Robert Archibald, Hereford.
Giles Richard Burt, Bridport.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE VIII.

CHARACTERISTICS OF THE TWO GREAT KINGDOMS OF NATURE.

GENTLEMEN,—Having already announced my intention of arranging the articles of the materia medica in natural historical order, I proceed in this lecture to give you an outline of the leading divisions which it will be necessary to make.

The terms nature and universe are frequently used as synonymous: and hence, under the head of natural bodies would be included the planets, fixed stars, &c. It is usual, however, to restrict the terms, so as to comprehend the terrestrial bodies only; which, then, are the objects of natural history and of natural historical classifications. Formerly they were divided into three groups, called kingdoms—the mineral, the vegetable, and the animal; but this division has, of late years, been for the most part given up, on account of the impossibility of so characterizing the two latter as to distinguish them from each other. To obviate this difficulty, the two have been formed into one, under the name of the *organized* or *living* kingdom, while the mineral is now called, in contradistinction, the *inorganized* kingdom.

But it has been asserted by some, that no more distinction exists between the organized and the inorganized kingdoms, than between vegetables and animals. There is a group of the latter called, by some of the German zoologists, the *lithozoa* or *stone animals*; on account of their supposed resemblance to a mass of mineral matter. In these the skeletons are external, or cutaneous, and consist of carbonate of lime (sometimes with a little phosphate) agglutinated by gelatinous matter. Here are specimens of these calcareous masses [shewing some madrepores and millepores], which have been supposed to connect the animal with the carbonate of lime of the mineral kingdom. But you will observe that the calcareous masses of the lithozoa are porous, and in the recent state contain fleshy tubes (called polypes) constituting the soft parts of the animal: a structure, nothing analogous to which is found in the mineral carbonate of lime. In the nullipora the pores are not evident, and hence these masses have been supposed to form the closest relation to minerals.

Vegetables also have been stated to be closely related to animals. Here is a drawing of the *Diatoma vulgaris* (fig. 24),

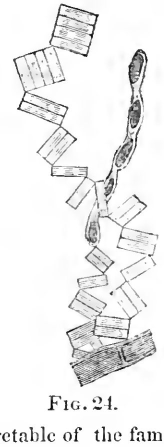

FIG. 24.

a little vegetable of the family *Algæ*; it varies in its form, and in the mode of connexion of its parts. At one period of its existence it is cylindrical, at another it is composed of quadrangular segments, sometimes connected by their sides, at others by their alternate angles. You will observe that these segments have somewhat the forms and appearance of crystals; and Agardh has, in consequence, fancied they form a distinct passage from the vegetable to the mineral kingdom; but their

active properties, the changes they undergo at the different periods of their existence, sufficiently distinguish them.

That vegetables and animals approximate and gradually pass into each other, I have already stated. The German zoologists have a class called *Phytozoa*, including all those animals which resemble plants. In some cases, animals resemble flowers in their appearance; as the different species of *actinia*, or sea anemones (fig. 25).

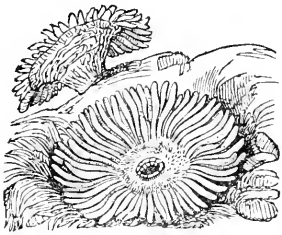

FIG. 25.

On the other hand, vegetables have oftentimes a close relation, in their external characters, to animals. Observe these *algæ* (pointing to some drawings): here are the oscillarias; vegetables having a cylindrical form analogous to the common earthworm, and, like it, also presenting a jointed appearance, from the junction of the segments composing its interior tube. Now these beings are endowed with the power of motion, as if voluntary, like animals. We have depicted *tendaridea pollux* (fig. 26) as an example of the tribe of plants called *conjugatæ*, on account of their having a kind of copulation. Two of these tubes approach each other, and become connected: we then observe that the green-colouring matter (which in each has a star-like form) passes from the joint of one into the joint of the other, and forms there a roundish gemmiform body, which subsequently becomes a new being. In the *zoocarpeæ* we have beings in which the vegetable and animal states

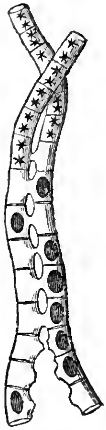

FIG. 26.

appear to succeed each other. Here is the *anthophysis dichotoma* (fig. 27), the tubular

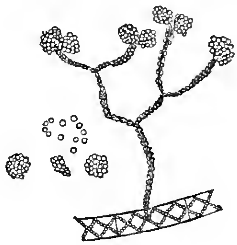

FIG. 27.

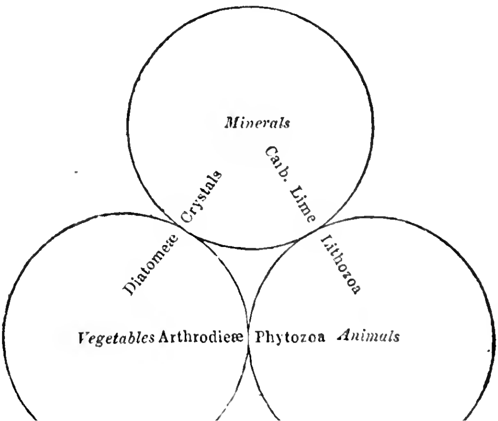
filaments of which produce, at their extremities, little globules, which, when detached from their support, possess a locomotive power, and (according to Bory St. Vincent) become a multitude of zoocarpeæ, or animated monads.

We see, thus, in what way it has been supposed the mineral, vegetable, and animal groups approach each other: and may adopt the mode of illustration as represented by the following diagram:—

FIG. 28.



The chief supporters of this opinion are Robinet and Schweigger. I must refer you to their works for further information, as also to Tiedemann's Physiology.

I propose, in the next place, to point out those characters which distinguish the organized from the inorganized kingdom, under three heads:—

1. Differences in chemical composition.
2. Differences in external and internal forms and arrangement of parts.
3. Differences in the actions, or motions.

I propose also to arrange them in a tabular form, so that the contrast between the two kingdoms may be instantly perceived.

1. Differences in Chemical Composition.

Inorganized Bodies.	*Organized Bodies.*
1. The undecomposed or elementary substances are fifty-four in number — namely, oxygen, chlorine, bromine, iodine, fluorine, hydrogen, carbon, nitrogen, phosphorus, sulphur, selenium, boron, silicon, potassium, sodium, lithium, magnesium, calcium, barium, strontium, aluminum, glucinum, zirconium, yttrium, cerium, thorium, tellurium, arsenicum, antimony, chromium, uranium, molybdenum, tungsten, columbium, titanium, gold, silver, platinum, palladium, rhodium, iridium, osmium, mercury, bismuth, copper, tin, lead, cadmium, zinc, cobalt, nickel, manganese, iron, vanadium.	1. The undecomposed or elementary substances are about twenty — namely, oxygen, chlorine, bromine, iodine, fluorine, hydrogen, carbon, nitrogen, phosphorus, sulphur, silicon, potassium, sodium, calcium, magnesium, aluminum, iron, manganese, gold, and copper. Of late it has been asserted that titanium is present in the renal capsules. Of the above-mentioned twenty elements in organized beings, only three or four are met with in considerable quantity — namely, oxygen, hydrogen, carbon, and nitrogen.
2. Are sometimes simple, or elementary; and, when compound, sometimes contain only two elements.	2. Are never simple. Every living part contains three or four elements at least, and frequently more.
3. The compound atoms are capable of decomposition and of recomposition.	3. Organized or living parts may be decomposed, but cannot be recomposed.
4. Are incapable of undergoing fermentation and putrefaction.	4. Are capable of undergoing fermentation and putrefaction.

These I conceive to be the leading chemical peculiarities. There are, however, several points which perhaps I should have added to these; but I have not done so, since they involve some hypothetical details. Thus Berzelius says that the inorganic *compound atoms of the first order* are always *binary;* whereas those of organic bodies are *ternary*, or *quaternary*. Water and sulphuric acid, for example, are each binary compounds; the first containing hydrogen and oxygen, the second oxygen and sulphur. It is, however, assuming too much to say that the compound atoms of organized beings, which are called *organic principles*, are always ternary, or quaternary. It is a fact that sugar consists of

Carbon, 6 parts by weight, or equal to	1	atom.
Hydrogen, 1 part do. do.	1	do.
Oxygen, 8 parts do. do.	1	do.

But it does not follow that it is a ternary compound: it may be a double binary compound of water and carbon. Thus an atom of sugar (an organic product) may be considered theoretically either way:—

$$\left.\begin{array}{lr} 1\text{ water} \ldots\ldots & 9 \\ 1\text{ carbon} \ldots & 6 \\ \hline & 15 \end{array}\right\} \text{ or, } \begin{array}{lr} 1\text{ hydrogen} \ldots & 1 \\ 1\text{ oxygen} \ldots\ldots & 8 \\ 1\text{ carbon} \ldots\ldots & 6 \\ \hline & 15 \end{array}$$

Several bodies which are composed only of two elements—namely, of carbon and hydrogen—are organic products: and although it is true, as mentioned before, that organized matters have three or four elements, yet all organic substances have not; for example, the stearoptene of the oil of roses. Berzelius has offered another distinction equally theoretical. He asserts the electro-chemical states of the compound atoms of inorganized bodies depend on the nature of their elements; while those of organized bodies do not. The following table will illustrate his views:—

	Hydrogen.	Carbon.	Oxygen.
100 parts of Sugar consist of	6·6	39·9	53·3
100 parts of Acetic Acid consist of	4·	48·	48·
100 parts of Oxalic Acid consist of	0	33·3	66·
100 parts of Carbonic Acid consist of	0	27·27	72·72

Now you will observe that sugar, which consists of oxygen united to hydrogen and carbon, possesses neither acid nor basic properties; or, at least, it possesses them in so feeble a degree, that they are only developed under particular circumstances. But acetic acid, which is composed of the same elements, is a powerful acid; and, therefore, we should expect, *à priori*, to find its oxygen (the most energetic electro-negative of its elements) in larger quantity than in sugar, whereas the reverse is the case. Again, carbonic is a very feeble acid, although it contains more oxygen than the oxalic acid, while the latter is more powerful. At one time I felt disposed to adopt Berzelius's opinion, that the peculiarities in these substances were referrible to their organic source; but as we meet with peculiarities equally great in bodies which are not organic, this doctrine seems now untenable. Two or three bodies (both inorganic) may be identical in composition, though different in properties. Thus there are three acids, all composed of—

$$\left.\begin{array}{lr}2\ \text{Phosphorus}\ldots\ldots & 32\\ 5\ \text{Oxygen}\ \ldots\ldots & 40\end{array}\right\}70$$

Yet each possesses peculiar properties, and hence they have been separately named: they are phosphoric, pyro-phosphoric, and meta-phosphoric acids. Such substances are said to be *isomeric* (from *ισος*, equal, and *μερος*, part.)

Let us now proceed to examine the differences in the external and internal form and arrangement of organized and inorganized bodies.

Differences in External and Internal Form and Arrangement.

Inorganized Bodies.	*Organized Bodies.*
1. The volume is variable and indefinite.	1. The volume is variable, but definite. Thus though men vary in their size, there is a limit to the variation.
2. The exterior form may be regular or irregular. When regular, these bodies are bounded by straight lines, and have angles; in other words, the *regular form* of inorganised bodies is *crystalline*.	2. The exterior form is regular, and generally rounded. To this, however, we have exceptions in some of the *Diatomeæ*, which, at one period of their existence, are angular.
3. The internal arrangement of the parts, or the *structure*, may be regular or irregular. If regular, it is crystalline.	3. The internal arrangement of the parts, or structure, is regular. This regular arrangement is vesicular or tubular.
4. Are generally composed of solid, liquid, or gaseous matter, exclusively: some exceptions, however, to this statement exist. Dr. Brewster has discovered colourless and transparent liquids in some topazes, chrysoberyl, &c.	4. Always consist of both solids and fluids. *Musci* and *Polygastrica* may, indeed, be dried without destroying their vitality; and hence they may be said to form exceptions to this statement. But they are probably never so dried as to be wholly deprived of moisture; and, in the next place, in this dried state they give no sign of life; and it is only by moistening them that the vital phenomena become apparent.
5. The separate parts are generally homogeneous, though sometimes heterogeneous.	5. The separate parts are essentially heterogeneous; that is, they possess different properties.
6. The separate parts are independent of each other.	6. The separate parts are always related, and in some cases are dependent on each other. This subserviency of one part to the other constitutes what is called *organization*, the parts being called *organs*.

Such are the principal points which I think it necessary to mention under this second head of the differences between organized and inorganized beings. I now proceed to the third head—namely, differences in actions or motions.

Differences in Actions or Motions.

Inorganized Bodies.	*Organized.*
1. Are produced by the agency of cohesion and affinity, at the expense of other previously existing bodies.	1. Are produced by other similarly constituted bodies, which we call the parents. There are, indeed, many cases in which we cannot demonstrate the existence of a parent; but several reasons lead us to conclude there was one. Hence we adopt as a canon, the statement of Harvey, "*Omni virum ex ovo.*" Cohesion and affinity are insufficient to account for the production of organized beings, and hence we call to our aid another power, which we denominate "*the vital force.*"
2. The preservation or existence is effected solely by cohesion and affinity.	2. The preservation or existence is frequently in opposition to the usual operation of cohesion and affinity: hence we refer it to "*the vital force.*"
3. Are in a state of rest.	3. Are in a continual state of activity, taking in from the external world certain solid, liquid, and gaseous substances, assimilating them to their own proper fluids, and converting them into solids, or preparing peculiar liquids from them. These phenomena constitute the process called *nutrition.*
4. Undergo no alterations in their nature, except such as result from the operation of attraction and repulsion.	4. Are incessantly undergoing changes, so that at different periods of their existence their properties are somewhat different. Thus they increase, develop themselves, arrive at maturity, and lastly decrease. The phenomena of *age*, therefore, are peculiar to organized beings.
5. The active properties are always the same in degree and kind.	5. The active properties vary in degree and kind: the distinction of *health* and *disease* which depends on this variation is, therefore, peculiar to organized beings.
6. The existence is not necessarily limited or definite.	6. Exist only for a limited period. The cessation of their existence is denominated *death.* The oldest organized beings on our planet are probably the *Baobab* trees (*Adansonia digitata*); the ages of some of which have been computed to be five or six thousand years. Though there is, perhaps, great exaggeration in this calculation, yet these trees are undoubtedly very aged.
7. All their actions are referrible to repulsion and attraction.	7. Repulsion and attraction are insufficient to explain the phenomena of living beings: we therefore admit other properties, called *vital*, which we refer to *life*, or the *vital force.*

We see, then, that the peculiarities of living beings, in reference to their actions or motions, are connected with their *origin*, their *development*, their *preservation*, and their *end.*

In considering the articles of the materia medica, it matters little whether we commence with those derived from the organized, or those from the inorganized kingdom. On the present occasion, I shall commence with those derived from the former.

Medicines derived from the Organized Kingdom.

This division includes two great groups, the animal and the vegetable, but which cannot be absolutely separated from each other. I propose to commence with the animal, and hereafter, when speaking of the vegetable, to throw into a tabular form

the principal characters which distinguish one from the other.

Animal Materia Medica.—The animal substances used in medicine were formerly much more numerous than now. At the present time they are far inferior, both in number and value, to either vegetable or mineral substances. The album græcum, mummies, the cranium hominum raspatum, viper's fat, &c. have long since ceased to constitute a part of our materia medica. With the exception of cantharides and leeches, we could easily dispense with the whole of them.

Zoological Classifications.—Although not very numerous, yet animal medicines require to be spoken of in some systematic order. Now many methods present themselves; we may, as some authors have done, divide them into whole animals, parts of animals, animal secretions, &c.; or we may arrange them according to the natural historical properties of the animals from whence they are obtained. I shall adopt the latter mode.

Now a natural-historical method must be founded on the properties of the bodies classified. But all the properties of an animal are not equally serviceable for our purpose; for some are accidental, some are temporary, others are variable, and comparatively only a few are so constant and invariable as to be available in natural history. The latter are *external form* and *structure*, and from the use we make of them, we call them *natural-historical properties.*

I ought, however, to premise, that although we talk of a natural arrangement, yet the only absolute and invariable distinction established by nature is that of *species.* But species possess so many characters in common, that it is impossible to distinguish them by any single trait of their organization; and thus, in order to diminish as much as possible the number of characters requisite to distinguish each species, naturalists have established groups, each containing those beings which are most analogous. Thus a group of species constitutes a *genus,*—the combination of analogous genera is termed a *tribe* or *family,*—the reunion of tribes forms an *order,*—while a *class* is the combination of orders.

The first systematic classification of animals was that of Linnæus, in 1735; and was as follows:—

			Classes.
Animals	having a heart with two auricles and ventricles: blood red and warm	viviparous	1. Mammalia.
		oviparous........	2. Aves.
	heart with one auricle and ventricle: blood red and cold......	having lungs	3. Amphibia.
		having branchiæ..	4. Pisces.
	heart with one ventricle: blood white and cold	having antennæ ..	5. Insecta.
		having tentacula .	6. Vermes.

The present course of lectures is not adapted for pointing out the defects of this arrangement; it is sufficient for me to state, that so early as 1795 Cuvier did this, in a *Memoir on Animals with White Blood;* and three years subsequently he proposed a new classification, the basis of which has been adopted by a large majority of naturalists throughout Europe. The following is a sketch of its leading divisions:—

General forms.

I.—Vertebrata.

Classes.

1. Mammalia.
2. Aves.
3. Reptilia.
4. Pisces.

II.—Mollusca.

5. Cephalopoda.
6. Pteropoda.
7. Gasteropoda.
8. Acephala.
9. Brachiopoda.
10. Cirrhopoda.

III.—Articulata.

11. Annelida.
12. Crustacea.
13. Arachnida.
14. Insecta.

IV.—Radiata, or Zoophyta.

15. Echinodermata.
16. Intestinalia.
17. Acalepha.
18. Polypi.
19. Infusoria.

Modifications of this arrangement, some of which are of considerable importance, have been made by different writers. Here are two—one by Goldfuss, the other by my able colleague, Dr. Grant.

Goldfuss's Arrangement.

XI. Mammalia.
X. Aves. IX. Reptilia.
VIII. Pisces.
VII. Mollusca.
VI. Insecta. V. Polymeria.
IV. Radiaria.
III. Annulata. II. Enthelmintha.
I. Protozoa.

Dr. Grant's Arrangement.

I. *Spino-cerebrata*, vel *Vertebrata.*

1. Mammalia.
2. Aves.
3. Reptilia.
4. Amphibia.
5. Pisces.

II. *Cyclo-gangliata*, vel *Mollusca.*

6. Cephalopoda.
7. Pteropoda.
8. Gasteropoda.
9. Conchiphera.
10. Tunicata.

III. *Diplo-neura*, vel *Articulata.*

11. Crustacea.
12. Arachnida.
13. Insecta.
14. Myriapoda.
15. Annelida.
16. Cirrhopoda.
17. Rotifera.
18. Entozoa.

IV. *Cyclo-neura*, vel *Radiata.*

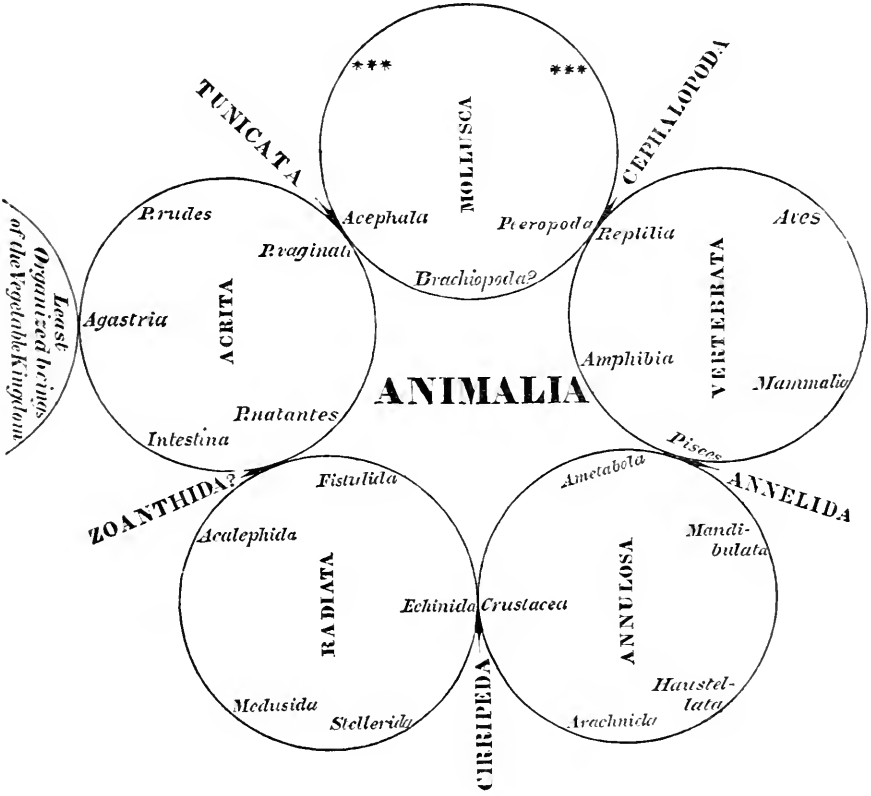
19. Echinoderma.
20. Acalepha.
21. Polypiphera.
22. Poriphera.
23. Polygastrica.

You will observe that the number, names, and position of the classes, differ from those of Cuvier's classification.

I cannot resist alluding to the *Quinary system*, proposed by Mr. MacLeay, in his *Horæ Entomologicæ*, being totally different from the Cuvierian method, and having obtained considerable celebrity of late years in this country. Every natural group is supposed by him to be resolvable into five natural groups, and each of these again into five other groups, and so on to the end of the term. Now this supposition, that nature always proceeds by fives, seems to me the most objectionable part of the arrangement. Mr. MacLeay imagines each group returns into itself, and he expresses this distribution by circles.

The following are his primary divisions, [Fig. 29]:—

Fig. 29.



You will observe that in Mollusca two classes are still wanting to complete the quinary arrangement of that sub-kingdom. The divisions acrita and radiata have been remodelled by Mr. Richard Owen.

For a further account of this classification, I must refer you to Mr. Mac Leay's work, or to the Report on Zoology of the fourth meeting of the British Association in 1834.

Schweigger, Oken, Blainville, Fleming, and others, have proposed new classifications, but in these lectures it would be improper to enter into any details respecting them. I shall follow the most generally adopted classification—namely, that of Cuvier, but adopting the modifications of Dr. Grant.

Arrangement of animals.—Some animals have a brain and spinal marrow: when this is the case, these parts are lodged in a bony cavity. These animals are the *Vertebrata* of several authors,—the *Spini-cerebrata* of Grant: for example, quadrupeds, birds, and fishes.

Animals having no spinal marrow are destitute of an internal skeleton: the nervous system possesses no osseous cavity in which it is lodged. These are the *Invertebrata* or *Evertebrata* of authors. They include the *Molluscous*, or soft animals, as shell-fish, slugs, &c.; the *Articulata*, or jointed animals, as insects and spiders; and the *Radiata*, or Zoophytes, as corals, star-fish, &c.

Animalia	Vertebrata.	
	Invertebrata	Mollusca.
		Articulata.
		Radiata.

Division 1. *Vertebrata*, or *Spini-cerebrata*.—They have an internal osseous skeleton, generally covered by muscles; their nervous system consists of brain, spinal marrow, ganglia, and nerves, the two first contained in an osseous envelope formed by the cranium and vertebræ. The blood is red; the heart muscular, with at least two cavities. The senses are five, the external organs for four being lodged in the head. The body is symmetrical, the limbs not exceeding four. The sexes separate. They are divided into five classes.

				Classes.
Vertebrata	hot blooded		viviparous: sanguineous globules circular	1. Mammalia.
			oviparous: sanguineous globules elliptical	2. Aves.
	cold blooded	in the adult state, respiration by lungs	heart with two auricles: squamiferous	3. Reptilia.
			heart with one auricle. In their early state have an aquatic respiration, and breathe by branchiæ: skin naked	4 Amphibia.
		respiration by branchiæ		5. Pisces.

Class I. *Mammalia.*—The animals of this class are born alive, and require a particular kind of food to nourish them in the first period of their infancy. Hence the mothers are supplied with *mammæ*, or breasts, for the secretion of milk; and from this circumstance these animals are called mammalia, or mammals. The bodies of most of them are furnished with hairs, and hence they have been called by Blainville, *Pilifera*. The characters of the class are the following: the blood is red and warm, having circular globules. The heart has two ventricles and two auricles, the circulation being double, that is, pulmonary and systemic. The respiration is by lungs, a diaphragm being present. We make nine orders of them:—

						Orders.	Examples.
Mammals	Piliferous: two pairs of members	unguiculated	three kinds of teeth	— hands	two	1. *Bimana*.	Man.
					four	2. *Quadrumana*.	Monkey.
				no hands	no abdominal pouch	3. *Carnaria*.	Dog.
					abdominal pouch	4. *Marsupialia*.	Kangaroo.
			not more than two kinds of teeth		no canines	5. *Rodentia*.	Beaver.
					no incisors	6. *Edentata*.	Sloth.
		hoofed	stomach simple (non-ruminants)			7. *Pachydermata*.	Pig.
			four stomachs (ruminants)			8. *Ruminantia*.	Musk
	Pisciform: naked skin: one pair of members					9. *Cetacea*.	Whale.

Order I. *Bimana.*—This order, which contains only one genus, *man*, is recognised by having hands (that is, extremities with thumbs free, and opposed to the fingers) on the upper extremities only.

Formerly, several substances obtained

from man were used medicinally. Even so late as the year 1782, in the fourth edition, by Schreber, of Linnæus's Materia Medica, we find mummies, the cranium hominis raspatum præparatum, human bones, and human fat, still placed among the articles employed as medicines. Thanks to the march of intellect, such disgusting and useless articles are now expunged from our catalogue of drugs. It is really quite amusing to read old Pomet's account of these articles. He first tells us how pretended mummies are manufactured, and then points out the characteristic marks of what he supposed to be genuine ones. "Choose," says he, "what is of a fine shining black, not full of bones or dirt, of a good smell, and which, being burnt, does not stink of pitch!" It seems also, according to the same authority, that the executioner at Paris was the grand purveyor of human fat "to those," as Pomet says, "who want it." Sometimes the *rock* or *stone lichen*, now called by botanists *parmelia saxatilis*, has been found growing on half-buried skulls: hence this was used in medicine under the name of the "*moss of dead men's skulls.*" Pomet tells us that the "English druggists generally bring these heads from Ireland, that country having been remarkable for them ever since the Irish massacre"

Without entering further into these absurdities, I may remark, that blood is the only article obtained from our species which is now employed as a remedial agent.

Transfusion.—The operation of transfusion consists in introducing the blood of one animal into the veins of another. It has been applied in the human subject to obviate the effects of hæmorrhage, and more especially that from the uterus. Although this operation will no doubt be brought under your notice by your surgical and obstetric teachers, yet there are one or two points to which I purpose drawing your attention.

Libavius, so early as the year 1615, speaks of this operation as practicable; and between the years 1660 and 1670, various experiments were made on the subject, by Lower, Denys, King, and others; but the practice fell into disuse. It must be recollected, however, that the old experimenters injected brute blood into the veins of man, instead of employing human blood; and that they resorted to the operation for the purpose of curing diseases, whereas it is now proposed as a remedy for hæmorrhage; and it is well established, that the blood of the same species only can be safely injected. This last fact has been proved by the experiments of Dr. James Blundell, to whom the profession is principally indebted for demonstrating the practicability of the operation.

It is universally known, that when animals are bled largely, they soon fall into a condition somewhat resembling death, and which is called syncope; and that if the quantity of blood lost be very great, *real* soon succeeds this *apparent* death. Now it has been proved that throwing into the veins a certain quantity of blood just drawn from another animal of the same species, will oftentimes avert the fatal event; but that if the blood of an animal belonging to a different, though neighbouring, species be employed, temporary resuscitation only is produced, the animal eventually dying. If the blood be taken from an animal whose structure, &c. is quite different from that of the animal who has lost the blood, temporary resuscitation even is not produced, but the blood thrown in seems to act as a poison.

These facts clearly prove that in each species the blood possesses peculiar properties. If we submit this fluid to a microscopic examination, we find it consists of a *serous liquid*, holding in suspension a number of *small, insoluble, and regular particles*, denominated *globules*, which seem to constitute the most essential part. Each of these has been described as consisting of two parts—namely, a *central corpuscule*, usually stated to be transparent or whitish, and a *membranous envelope*, having a gelatinous character, and generally said to possess a reddish tint. Now as these globules are peculiar to the blood, and as they vary in shape, number, and size, in different species of animals, it is probable that it is to their variations of characters we are to attribute the fact already stated—namely, that permanent resuscitation cannot be effected except by blood of the same species.

Confining our attention to vertebrata, we find in mammals the particles are circular; but in birds, reptiles, and fishes, elliptical (fig. 30). Observe the represen-

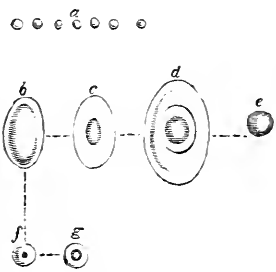


FIG. 29.

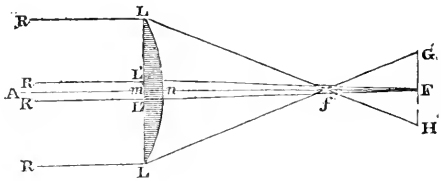
tation of the so-called globules of human blood (*a*), which are flattened circular discs, and not spheres, as their names would indicate. There are no central nu-

clei, as described by several writers; the appearances supposed to be nuclei are only optical illusions: such, at least, is Raspail's opinion. In confirmation of it we have the evidence of Dr. Hodgkin, who has been unable to find them; and I have likewise searched for them in vain by means of an excellent microscope belonging to Mr. Goadby.

The optical illusion is perhaps best explained by reference to what is called *spherical aberration*. The rays of light refracted by spherical surfaces do not all meet at one point or focus: those nearest the axis form a focus much more distant from the lens than those most remote from the axis. Let us take the case of a plano-convex lens, in which this is best seen:—

Fig. 31.



L L, The plano-convex lens.
A F, The axis of the lens.
R' L' and R' L, Rays near the axis, forming their focus at F.
R L and R L, Rays more distant from the axis, forming their focus at *f*.
The distance between *f* and F is the spherical aberration of the lens.

If we view a luminous body through such a lens as this,—at *f* we shall have the circumference well illuminated, but not the disc; while at F the phenomena will be the reverse: that is, the disc will be illuminated, but not the circumference. Now the globules of the blood, though not spherical, may produce an analogous effect on the rays of light: the rays of light passing through them will not meet at the focus, because of their thickness not being uniform, and thus the appearance of *f* or *g* (fig. 29) may be put on.

Here is a representation of the oval or elliptical particles of the frog (*b*). After being for a few minutes on the object-glass of the microscope, and diluted with a little water, they enlarge, and a kind of nucleus becomes evident (*c*, *d*.) The outer layer then disappears, leaving the nucleus (*e*), which also subsequently disappears, by dissolving, or undergoing some other change in the water. Such is the account given of these globules by Raspail; its correctness I have myself verified. He refers the nucleus here to the successive solution of the different layers of the albuminous globule.

A priori we might expect that elliptical globules could not with safety be employed to replace circular ones, nor, *vice versâ*, circular globules to replace elliptical ones. Now the experiments of Prevost and Dumas confirm this opinion. When blood having circular globules was injected into the veins of birds, it not only did not support life, but acted as a poison, causing immediate death, accompanied with symptoms demonstrating some lesion of the nervous system. When the blood of one species having circular globules was injected into another species also having circular globules, the death was not immediate, but took place after some time, in consequence, apparently, of imperfect nutrition.

The number of globules contained in a given quantity of blood varies in different species of animals, though, from their minuteness, it is perhaps impossible to ascertain accurately their relative quantities. Now it is not at all improbable that this variation may have an important influence on the animal; but as the size of the globules usually varies with their number, it is difficult to determine their separate influence. The following table shows the number of particles contained in 1000 parts of blood, according to the observations of Prevost and Dumas:—

	Man.	Calf.	Horse.	Dog.	Cat.
Globules	129·2	91·2	92·0	123·8	120·4
Water	783·9	826·0	818·3	810·7	795·3
Albumen and soluble salts	86·9	82·8	89·7	65·5	84·3
	1000·0	1000·0	1000·0	1000·0	1000·0

All the blood here referred to was venous, except that of the calf, which was a mixture of venous and arterial.

The size of the sanguineous particles varies in different species, and there is good reason for suspecting even in individuals of the same species, though this last observation is denied by Petit and Dumas, who state that the diameter is constant in the same species. Cavallo, however, says the diameter of the globules of human blood varies from three-ten-thousandths of an inch to four-ten-thousandths. Raspail goes beyond this, for he says they vary from two-ten-thousandths to four-ten-thousandths of an inch. Now if we admit these statements we have a ready means of accounting for the discordant results obtained by different observers. However, my principal object in noticing the variable size of the sanguineous globules in the different species, was to remark that probably it is to this circumstance, in part at least, that the blood of one species will not answer for transfusion into an animal of another species. The elliptical globules of the frog are considerably larger than those of man: Raspail says they are one one-thousandth, and that of the salamander are as much as thirteen-ten-thousandths of an inch, being the largest known.

Hitherto the cases in which advantage has been obtained from transfusion, are principally those of uterine hæmorrhage. In operating, great care must be taken to avoid the introduction of atmospherical air, for this fluid may cause death, by obstructing the pulmonary circulation; or if the quantity of air be larger, it becomes dilated by the heat, and thus distending the heart with frothy blood, gives rise to instant death, attended with convulsions. But it has been shown that a much larger quantity of air may be thrown with impunity into the veins more distant from the heart than had been previously supposed.

Another point deserving your particular attention is, that the blood should be injected immediately after it has been drawn from the body; for when it has been exposed to the air for some minutes, and probably before it has distinctly coagulated, it is unfit to carry on the vital functions.

It is remarkable that the quantity of blood to be transfused is very small compared with that lost. In one case, related by Dr. Waller, four ounces only were required; in another eight ounces. It will rarely, perhaps, be necessary to employ more than twelve ounces.

The operation may be readily performed by means of a three or four ounce syringe; or the common enema pump might answer. I must refer you, however, to Messrs. Mawe's Catalogue of Surgical Instruments for drawings of the different kinds of transfusion apparatus; as also to the last, or seventh edition, of Denman's Midwifery, edited by Dr. Waller, where you will find a detailed account of the method of conducting the operation.

DR. ELLIOTSON ON LIFE AND MIND.

To the Editor of the Medical Gazette.

SIR,

MY last letter was devoted to an examination of Dr. Elliotson's proposition, that it is the brain which thinks, as clearly as that the liver secretes bile; wherein I endeavoured to show that such a proposition can never be established, for a variety of reasons, but chiefly because it is opposed to the fundamental laws of human belief. I conceded, nevertheless, that when stated as an hypothesis, it admits of being supported by a number of plausible arguments. To these arguments, as advanced by Dr. Elliotson, I would now call your attention.

"The brain thinks, and feels, and wills*." "To call the human mind positively a ray of the divinity appears to me absolute nonsense. Brutes are as really endowed with mind, with a consciousness of personality, with feelings, desires, and will, as man. Every child is conscious that it thinks with its head; and common language designates this part as the seat of mind; *e. g.* a stupid person is honoured with the expressions numbskull, thick head, &c. Observation shows that superiority of mind in the animal creation is *exactly* commensurate with superiority of brain, that activity of mind and of brain are *co-equal*, and that as long as the brain is endowed with life, and remains uninjured, it, like all other organs, can perform its functions, and mind continues; but, as in all other organs, when its life ceases, its power to perform its function ceases, and *the mind ceases;* when disease or mechanical injury affects it, the mind is affected; inflammation of the stomach causes vomiting—of the brain, delirium; a blow upon the loins suppression or alteration of the urine; a blow upon the head stuns; if originally constituted defective, the mind is defective; if fully de-

* Page 39.

veloped and properly acted on, the mind is vigorous; accordingly, as it varies with age, in quality, and bulk, is the mind also varied. The mind of the child is weak, and very excitable; of the adult, vigorous and firm; and of the old man weak and dull, *exactly* like the body; and the character of the mind of an individual agrees with the character of his body, being equally excitable, languid, or torpid, *evidently* because the brain is of the same character as the rest of the body to which it belongs. The female mind exceeds the male in excitability as much as her body. The qualities of the mind are also hereditary, which *they could not be* unless they were, like our other qualities, corporeal conditions; and the mind is often disordered upon the disappearance of a bodily complaint, just as other organs besides the brain are affected under similar circumstances. The retrocession of an eruption may affect the lungs, causing asthma—the bowels, causing enteritis—or the brain, causing insanity. Phthisis and insanity sometimes alternate with each other, just like affections of other organs. The laws of the mind are *precisely* those of the functions of all other organs: a certain degree of excitement strengthens it, too much exhausts it, physical agents affect it, and some specifically, as is the case with other functions; for example, narcotics. The argument of Bishop Butler, that the soul is immortal, and independent of matter, because in fatal diseases the mind often remains vigorous to the last, is *perfectly groundless;* for any function will remain vigorous to the last, if the organ which performs it is not the seat of the disease, nor much connected by sympathy, or in other modes, with the organ which is the seat of the disease*."

It is not my intention to scrutinize minutely all the proofs adduced in these passages, although I think it might be shown that some, perhaps, ought to be rejected; that others are overstated; and that several are puerile. A few remarks on each will suffice to convey the opinion I am led to entertain of the value and character of the whole.

First. "Brutes are as really endowed with mind, with a consciousness of personality, with feelings, desires, and will, as man." Admitting this, what then? How does the fact that brutes possess mind prove that, in man, the brain is the mind? I see not how, unless the writer means to assume that it is certain, a thing universally admitted, that mind in a brute is nothing besides the brain. So far from granting such an assumption, I think there is reason to infer that brutes possess an immaterial principle, or entity. I say, reason to *infer* this, from observation; for I want, in reference to the nature of brute mind, other two kinds of evidence—viz. consciousness and testimony, which I possess with regard to the nature of the human mind. It ought to satisfy the inquirer, if I am able to show that in man, *that* which thinks is not the brain, without its being necessary that I should entangle myself with an extraneous question concerning the nature of inferior orders of mind. My knowledge of the minds of brutes is both inexpressibly limited and imperfect; even the end for which the greater proportion of animals exists at all, is, I confess, utterly beyond my comprehension. Although, therefore, I might be excused if I were to pass without notice this argument of Dr. Elliotson, I choose rather to entertain it, feeling that to deny to brutes the possession of an immaterial principle, in the face of a degree of evidence for the fact, *merely* because it may shock the prejudices of the vulgar to admit that brutes have souls, is unworthy of intrepid reason.

Second. It is incorrect to assert that "every child is conscious that he thinks with his head;" the fact being that every person, capable of reflection, is conscious that it is with his mind that he thinks. It is only by experience that he at length is aware that the head is the chief seat of the mind. Were the four senses which are placed in the head—hearing, sight, smell, and taste, situated more remotely from the brain, suppose on the thorax (and by imagining the prolongation of their nerves this is conceivable), probably it would not be so readily discovered, as it now is, that the head is in a peculiar sense the instrument of the mind. It is from having to move the head to accommodate the eye in seeing, and the ear in listening, and by the infinite variety of other movements the head is made to perform in the exercise of these senses—the prime ministers of the mind—together with the sudden interruption of the mental operations produced by blows on this part of the body, that every one insensibly acquires the conviction that the residence of thought is there. A person is not, therefore, conscious of thinking with his head; but he infers that the conscious mind employs the head in its operations.

Third. "Superiority of mind in the animal creation is *exactly* commensurate with superiority of brain." This is an incautious assertion, if by "superiority" is to be understood largeness, or some particular form of the head, since these are at present points confessedly of doubtful disputation, and likely so to continue. Besides, Dr. Elliotson is well aware that insects, the

* Page 37. It is only fair to remark, that the words in Italics are not in that character in Dr. Elliotson's text.

most reasoning, perhaps, of all the inferior creatures, have properly no brain, a slight enlargement of the upper extremity of the spinal marrow being all that stands for that organ *.

Fourth. " Activity of mind and brain is coequal." If the writer believes, as he affirms, that it is the brain which thinks, what sense is there in saying that two names—brain and mind—implying the same thing, possess co-equal activity? which, on his hypothesis, is as void of meaning as if a lapidary should announce, in reference to the same precious stone, that the hardness of the diamond and of the brilliant is co-equal! But if, on the other hand, it be not a settled point, and this Dr. Elliotson will surely allow, that the living brain is the mind; on what ground, supposing that the brain and the mind are distinct substances, could any one pretend to determine that they possess co-equal activity? or by what signs detect inequality in this respect?

Fifth. " When disease or mechanical injury affects the brain, the mind is affected; inflammation of the stomach causes vomiting—of the brain, delirium; a blow upon the loins suppression or alteration of urine; a blow upon the head stuns." How convenient is the term " affects!" The mind is affected by a blow upon the head, and the kidney is affected by a blow on the loins; therefore it is the head that thinks, as obviously as that it is the kidney that secretes the urine; a blow equally affects both, and thus is established a sound and perfect analogy between the two organs! But every thing in nature is liable to be *affected*: an earthquake " affects" a whole province; moisture affects a violin; and bad news affects the funds: hence, to be affected is no proof of there being analogy in the nature of the different affections. Although it be true that inflammation of the brain affects the mind with delirium, and inflammation of the stomach affects that organ with vomiting, what conceivable analogy is there between delirium and vomiting? Surely it is not on such confused reasoning as this that the student ought to admit the proposition that it is the brain which thinks? Doubtless it is true, in general, that disease and mechanical injury of the brain ultimately impair, suspend, or derange, the operations of mind; but every experienced pathologist is aware, that the effects on the mind resulting from diseases of the brain are wonderfully little uniform in their character. There is evidence that, in numberless cases of disorganizing disease of the brain, the mind remains apparently perfect until the malady has existed for weeks, or even for months, and produced extensive ravages. The opinion of so eminent a pathologist as Dr. Allison, in regard to the influence of organic cerebral disease on the mind, is well worthy of attention. "The very same kinds of alteration of the mental faculties," says Dr. Allison, " have often been observed from disease or injury of very different portions of the brain; and again, large and various portions of the hemispheres of the brain have been found, in other cases, manifestly injured, or even destroyed by disease, without perceptible alteration of the mental faculties, almost to the moment of death. Experiments and pathological observations would seem to indicate, therefore, that the manifestation of these mental phenomena depends not so much on the mere presence of any particular quantities of the nervous matter of the hemispheres, or the forms which it presents, as on some other conditions in that nervous matter *."

I am far from intending to insinuate that the nervous system is not the organ by which the mind, to a certain extent (we know not to what extent), operates; or that the same system is not necessary, in some inscrutible manner, to the manifestation of mind, as the attribute of a human being; but the deliberate opinion of Dr. Allison may serve to caution the student against reposing implicit confidence in vague unwarrantable comparisons between the disorders of the mind and the disorders of a secretory gland.

Granting that disease, malformation, and mechanical injury of the brain, variously affect the mind (for these are established facts), we ought not to forget that there are other facts of an opposite and countervailing kind, in reference to the influence of the mind upon the brain and the whole body, equally well established. If it be true that cerebral disease disorders the mind, the converse is equally true—namely, that certain purely mental affections disorder the physical frame. Emotions and other mental states—emotions, it may be, not excited directly by external circumstances, but originating in a process of reasoning, will, even in the most vigorous and healthy person, produce bodily disease, or sometimes death itself. Here it is obvious, that if, in delirium or stupor resulting from disease or injury of the brain, the state of the bodily organ stand

* Dr. Elliotson, as an instance of reason in brutes, mentions an anecdote of the wasp, on the authority of Darwin.

* Allison's Physiology, &c. &c. p. 238.

in the relation of *cause* to the mental disorder, equally true is it that in such disorders as syncope, convulsions, diarrhœa, palsy, fever, abortion, amenorrhœa, produced by sudden emotions, the *cause* is not a bodily but a mental state; the proof of which is not inferential, as in the instance of a mental disorder ascribed to cerebral disease as its cause, but matter of distinct consciousness. In disease of the brain, attended by delirium or insanity, a doubt may be insinuated as to whether the cerebral disease is the cause of the mental disorder, seeing that violent affections of the mind oftentimes result from disease of distant organs in the absence of disease of the brain; but in the instance of syncope, or any other disorder suddenly produced by emotion, no such doubt can be insinuated; because the person affected is conscious (it is not an inference); he is conscious that the cause of his bodily disorder—the first phenomenon in the series—was a mental state. In a political revolution, or in a great commercial crisis, how numerous the victims of disease and death, caused solely by mental affections! The practical observer of life knows well that mortified vanity, rage, critical suspense, disappointment, sudden poverty, bereavement of those who are dear, remorse, are every day producing their dreadful effects; in such forms, too, as even the page of fiction most inadequately pourtrays. M. Georget, the celebrated writer on madness, remarks, that "among one hundred lunatics, ninety-five at least have become such from the influence of affections and moral commotions."

It is not alone, however, to states of mind as causes of disease that we are to have regard; they produce effects of a curative and salutary kind. Restoration of health, the incredible endurance of toil, of hunger and thirst, of solitary imprisonment, of the extremes of heat and cold, calmness in the view of a violent death, resistance of the most powerful contagions, are all often witnessed as the effects of temporary states of mind influencing the bodily frame. These states of mind, it is well worthy of remark, will sometimes be strengthened in a tenfold degree in a moment, or as instantly annihilated, by a single word of hope or of discouragement whispered in the ear, or by a single thought suggested in the course of solitary reflection: the instantaneous result being increased boldness and firmer determination; or irresolution, feebleness, and despondency.

Upon the whole, therefore, it is clear that the fact that injuries of the brain disorder the mind, cannot be admitted as proof that mind is the function of the brain; seeing that purely mental states can equally disorder the brain and the entire body, and, indeed, affect the body in a great variety of ways infinitely more wonderful than bodily states ever affect the mind.

Sixth. "The character of the mind of an individual agrees with the character of the body, being equally excitable, languid, or torpid; *evidently* because the brain is of the same character as the rest of the body to which it belongs." Whether what is here asserted to be *evidently* true, is true or not, cannot be proved. To suppose that the brain might be naturally torpid, and the rest of the body naturally excitable, or to suppose the opposite of this, appears to me to involve something like absurdity. As little meaning is there in the assertion that "the female mind exceeds the male in excitability as much as her body;" for if the mind is only the property of the body, the remark is needless; and if the mind is not a corporeal property, by what means is excitability of the body, apart from excitability of the mind, to be discovered? Surely it is natural to expect that the body and the mind of the same individual will be adapted for the production of union and harmony, whether the mind be a property of the brain or something different.

Seventh. "Qualities of mind could not" be transmitted, if they were not "corporeal conditions." How does Dr. Elliotson know? Every one *knows* that qualities of mind do often descend from parents to their children, but no one can pretend to *know* that mental qualities are actually corporeal conditions. The "could not," therefore, is not altogether in the true spirit of philosophical caution.

Eighth. "The laws of the mind are *precisely* those of the functions of all other organs:" of those of the kidney, for example. Does the writer mean that the laws of volition, or of the religious emotions, which are laws of the mind, are precisely similar to those which regulate the functions of the kidney in the secretion of urine? If this is not his meaning, I know not what different construction the passage admits of. Perhaps he means that certain only of the laws of the mind are precisely those of the functions of other organs; for here are his proofs:—"The laws of the mind are precisely those of the functions of all other organs; a certain degree of excitement strengthens it, too much exhausts it, physical agents affect it: and some specifically, as is the case with other functions—for example, narcotics." The term "excitement" here plays the part that "effects" did in a former passage. A certain degree of ex-

citement—the company and conversation of an agreeable friend—strengthens the mind precisely as a certain degree of excitement—the operation of a gentle diuretic—strengthens the kidney. Too much excitement—for example, the fear of shipwreck or of bankruptcy—exhausts the mind precisely as elaterium exhausts the kidney. Such a physical agent as opium "affects" the mind, causing sleep, dreaming, elysian visions, or tartarean horrors; and the same drug "affects" the kidney, causing the urine to be red and scanty. I disclaim the desire to draw from the writer's arguments ridiculous conclusions; but, unless I am deceived, this result is inevitable; for surely no dispassionate reasoner will contend that the terms "excitement," "strengthens," "exhausts," "affects," applied to the mind, have any analogous meaning when employed with reference to the kidney.

Ninth. "The argument of Bishop Butler, that the soul is immortal, and independent of matter, because in fatal diseases the mind often remains vigorous to the last, is *perfectly groundless:* for any function will remain vigorous to the last, if that organ which performs it is not the seat of the disease," &c. The words of the Bishop alluded to are, I presume, that often persons affected with mortal diseases are seen to possess "apprehension, reason, all entire; with the utmost force of affection, sense of character, of shame, and honour, and the highest mental enjoyments and sufferings, even to the last gasp"—facts which he imagines render it probable that such diseases will not be the destruction of our reflecting powers. It is, perhaps, not so clear that the Bishop's argument is "perfectly groundless;" for every attentive observer must have noticed instances of persons in whom life was all but extinguished, combating with languor, manifesting at intervals lively emotion, and uttering the most weighty sentiments. In general this is not the case. Commonly the mental operations become languid as sensation and the power of voluntary motion decline, so that in the last hours of life the mind, equally with the body, would seem to be falling a prey to the disease. The cause is obvious. The mind of most persons during health is, in a great measure, habitually under the influence of bodily sensations, the predominant bias having reference to "what shall we eat, and what shall we drink, and wherewithal shall we be clothed." In others, however, in whom the reflective faculties, and the religious and domestic affections, have been habitually cultivated, the last scene is very different. Here we often witness the torpid declining body compelled to give utterance, it may be in the feeblest accents or signs imaginable, to the most sublime sentiments and the tenderest feelings. There is an evident struggle against the influence that is sealing up the senses. Perhaps there is a wish to bear a dying testimony to the verity of religious hope, to utter a last word of affectionate advice, or to express dissent from an obnoxious proposition. In such a case we may witness the mind *voluntarily* and *deliberately* striving to collect and concentrate its powers for a last effort—attempting again and again, it may be unavailingly, to utter something, there remaining obviously the power to *will.* It is this war of the intellect against stifling pain, and the most overpowering languor and exhaustion, as life is ebbing, —one kind of nature striving to rise above, and for a moment triumph over a different kind of nature, — to which, doubtless, Butler refers in the passage of the Analogy Dr. Elliotson has alluded to. Whether or not the Bishop's inference—that it is *probable,* on the strength of such evidence, that death will not be the destruction of our reflecting powers — is "perfectly groundless," the reader who has studied the Analogy, and bears in mind the scrupulous, the timid caution of that wonderful writer in all his deductions, may be left for himself to determine.

There is probably a source of confusion and fallacy in the mind of Dr. Elliotson, of which he is utterly unaware, arising from his allowing himself to imagine that those who argue for the mind's being an entity, must hold, as a thing of course, a variety of fanciful opinions concerning the nature and essence of mind. On no other supposition can I account for his bringing forward several of the arguments which have been already noticed. It would seem he considers that those who take the side of the argument I am endeavouring to support, hold the mind to be a spiritual, immortal, perfect, *quasi* angelic intelligence, of which almost every thing ought to be predicated that might be predicated of an angel. I, however, beg to disclaim all such hypothetical fancies, as, indeed, I before disclaimed them. My opinions of the nature of mind I am desirous of forming with the same caution and deliberation I exercise in the investigation of other subjects: in proof of which, I allow, with Dr. E., that the mind varies with age; that, in a sense, it is weak, ignorant, and excitable in the child; vigorous and intelligent in the adult; and in the aged frequently—by no means always—comparatively dull; that it is greatly and variously affected by diseases and inju-

ries of the brain, as well as strikingly influenced by innumerable other forms of material agency. I am further willing to allow that (revelation apart) I have not discovered evidence on which I can fully rest, whether it ought to be regarded as immortal, or as being of limited duration, like the body. But I am compelled to confess, that if it possesses any quality in common with organic matter, I am wholly ignorant what that property is. The facts Dr. Elliotson has adduced to prove that the brain is the mind, and a thousand other facts of a similar kind, may very properly, perhaps, be employed in overthrowing the fancies he *attributes* to theologians. Further than this, they do not serve his purpose.

Dr. Elliotson deprecates the idea that his opinions on mind tend to materialism,—a doctrine which may be thus defined: mind never being found but in conjunction with a brain, we ought, as philosophers, to conclude that mind necessarily exists in, and results from, that organ, unless it can be shewn to be incompatible with other known properties of the same substance *. These, it is true, are not Dr. Elliotson's words; but several passages in his work evince that the sentiments differ little from his. For example, the qualities of the mind are "corporeal conditions." Again: "when the brain dies, the mind ceases." And further: "at death our being is utterly extinguished, and we go back to the insensibility of the earth, whence we were taken." But such sentiments are not those of a materialist: quite otherwise! "The assertion," says he, "that the mind is a power of the living brain, is not an assertion that is material: for a power or property of matter cannot be matter." In my former letter, this notion that a property of matter—blueness, sweetness, or hardness—is not matter, but something superadded thereto, and, it is to be presumed, immaterial, was briefly noticed. It no doubt may be said that sweetness,—to take that property as an instance,—is not the name of a material thing, but merely the name of a sensation caused by matter; but this would be a mode of evasion leading to utter absurdity; for though it is true that a sensation of sweetness is not matter, but a mental state, nevertheless we instinctively regard sweetness as not existing in the mind, but belonging to the particular material body which causes in us this sensation: in a word, we mean that it is the material body which is sweet. To affirm that the sweetness is something different from the material body, is equal to affirming that every other property of matter is something different from matter, and that no such thing as matter is known to us; which every one feels to be absurd. If, therefore, the mind be said to be a property of the brain,—and this Dr. E. maintains,—the only meaning I am able to attach to such a proposition is, that when a person, by the help of his senses, (and how otherwise can he examine the *properties* of a body?) examines the brain, he discovers mind—acquires the idea of mind, just as he perceives the property of sweetness when he examines the saccharine body by means of the organ of taste. However, be this as it may, to assert that the mind is a property of the living brain, is obviously equal to asserting that the mind is as much matter as the living brain is matter. Whether or not the living brain, or any other living organ, is more than matter, needs not again to be discussed. Possibly this explanation may be regarded as uncalled-for repetition; but surely so grave a fallacy as that a property of matter is *something different from matter*, requires to be freely exposed, in order that this species of argument being stripped of the mystery which it appears is ever ready to envelop it, the sophistical disputant may be prevented from taking to his usual refuge—mere words.

The opinions on mind which Dr. Elliotson would inculcate on the rising race of physiologists,—for it is to the student that his book will chiefly be acceptable,—lead by no circuitous route to Spinozaism—the most odious of all systems of speculation, inasmuch as it is not one of pure Atheism, but leaves us a kind of Deity whom we must for ever abhor. Not that Dr. E. is himself an avowed disciple of this system,—that I am far from affirming,—but it is plain that his chief reason for regarding the brain as being the mind, differs little from the main argument of Spinoza. The former cannot conceive of mind without a brain, and Spinoza merely extends and amplifies the same principle: for, perceiving nothing besides matter to exist, he infers that nothing but matter does exist. Indeed, if the evidence for mind's existence as a substance or entity be regarded as baseless or insufficient merely *because* we have no experience of its existence dissevered from organization, then is the existence of a creating, sustaining intelligence, distinct from "the things which are seen" incapable of satisfactory proof; since it may be fairly argued that if the medullary substance, brain, is endowed with power to feel, think, and will, and, in the exer-

* This definition of materialism differs little from that of Dr. Priestley.

cise of this power, operates on matter (as we know the mind does) with wonderful skill and extensive effect, it is probable that the material universe possesses a similar, though infinitely ampler, power: thus the brain being regarded as the mind, the universe will necessarily be regarded as the Deity.

Dr. Elliotson wanders far, I presume to think, out of his proper line, when he enters on the inquiry as to whether revelation affirms that we are more than mere bodies,—a question requiring more space, and, perhaps, a greater fund of knowledge for its solution, than the writer of an elementary treatise on human physiology can be expected to afford.

In incidentally touching on points of human science or speculation,—and they are never touched upon otherwise than incidentally,—revelation employs chiefly, we have every reason to believe, the language of the unlearned of those times, without in a single instance pretending to enlarge our knowledge of such matters, which would have been wholly foreign to its avowed object—the making known to men, the learned and the unlearned alike, the will of God for their salvation. Nevertheless, in many passages our Saviour intimates, it might seem casually, the conscious existence immediately after death of such as were then, as respects their bodies, dying, or already dead *. And St. Paul, there can be no question, believed that the death of his body would not suspend the enjoyment of his conscious mind. "While," says he, "we are at home in the body, we are absent from the Lord," affirming that he is "willing rather to be *absent* from the body, and *present* with the Lord." Further, he expresses a desire "to depart and be with Christ, which is far better." In a number of passages which authoritatively reveal the resurrection of the body, it is true the language presents great difficulties, and might, if taken separately and alone, be supposed to favour the belief that all we are descends at death into the grave. It is unquestionable, however, from the passages of scripture which have been quoted, (and the reader may augment their number tenfold by selecting parallel passages), that the New Testament writers, without pretending to determine whether the mind be or be not material, *admit* and *assume as true* the common belief of all ages, that the mind of man continues in conscious existence after the dissolution of the body.

It may be said, "what if it be true that medullary matter thinks?—If, in fact, it does so, it must be the best possible substance for thinking: the question is one, therefore, of little or no importance." Some such argument has been employed, but it possesses not even the slender merit of being plausible; for on similar grounds the Atheist might argue that the question as to the existence of a God is trivial, it being reasonable to infer that if, in fact, there is no God, the universe is better without a presiding power. The question is not at all whether it be best to believe what is true, but whether it be proper to reject the evidence of our own consciousness, in order to admit a gratuitous hypothesis, which being admitted, tends to heap contempt on human nature, and is directly opposed to the consoling belief of thousands of the despised and the miserable:—to that belief which the ill-favoured, the misshapen, the loathsomely and the incurably diseased (to mention no other forms of misfortune, and to allude to no higher considerations) naturally cling, that there is *that* within which, partaking in no degree of the repulsive defects of the body, entitles them to their proper rank in society, or, at all events, secures to them the sympathy and the respect due to a moral and intellectual nature, which not an abscess or a tubercle in the brain, but vice and ignorance alone, can really degrade.

Yours respectfully,
JOHN ROBERTON.

Manchester, Nov. 14, 1835.

* Luke, xii. 4 5, xvi. 27-28: also xxiii. 43, 46. These passages, when duly weighed, will be found decisive of the argument.

ON THE

INTERNAL USE OF SEA-WATER

IN VARIOUS DISEASES.

To the Editor of the Medical Gazette.

SIR,

SHOULD you deem the annexed paper, on the internal use of sea-water, worthy a place in the Gazette, I shall feel obliged by your affording it admission.

I am, sir,
Your obedient servant,
EDWARD GREENHOW, M.D.

North Shields,
Nov. 7, 1835.

Sea-water seems to have been a popular remedy for a great variety of diseases from a very remote period; and although many medical writers have

noticed it in favourable terms, it has never been generally taken up by the profession, and consequently has never occupied that place amongst remedial agents to which I think it is well entitled. Amongst the ancients who have written in its favour, are Hippocrates, Celsus, Asclepiades, Aretæus, Pliny, Marcellus, and Serenus, besides a whole phalanx of others; and nearer our own times, are Russell and Saunders, &c.

Sea-water, taken internally, exerts a powerful influence over various organs of the human body; its most obvious and immediate effect is upon the bowels and kidneys, producing copious evacuations from the one, and a large flow of urine from the other; it also has an influence upon the circulation, producing an acceleration of the pulse, and an increased temperature of the surface of the body. But its action by no means stops here: it stimulates the liver, and exerts some peculiar influence upon the glandular and lymphatic system, rendering it a most useful remedy in the treatment of strumous tumors and ulcers; and although its use is not applicable to other diseases where an inflammatory tendency exists, this does not hold good as respects scrofulous affections. The progress and decline of these complaints is so slow, that it would answer little purpose to detail the cases in which I have employed it, in conjunction either with cold sea bathing, or with warm sea-water baths. Its effects I have found much more efficient than those of iodine, or any other remedy with which I am acquainted.

In dyspepsia and chronic affections of the liver, my first attention to sea-water, as a remedy, arose from being frequently consulted by the lead-miners from Alston Moor, who flock in great numbers to Tynemouth during the summer, their ordinary sojourn at the sea-side being from two to three weeks; and it is astonishing the change for the better which is wrought in their appearance during that period. When they arrive there, they are generally thin and sallow, suffering from loss of appetite and impaired digestion, together with a torpid state of the bowels. Their usual mode of proceeding is to drink copiously of sea-water every morning, so as to act briskly upon the bowels, and also to bathe in the sea, not once only, but generally twice or even three times in the day. Something, of course, must be ascribed to change of air and of habits, and perhaps also to sea-bathing; but I am inclined to believe that the chief benefit they derive is from the internal use of the sea-water; and this belief led me to try its effect in dyspepsia and cases of torpid liver, and with the most decided advantage.

In the summer of 1834, I was induced to take it for about forty successive days; and as my own case will serve to illustrate its effects, I will relate it. I had been suffering for many weeks from indigestion; having weight and distention after eating, constant dull headache, impaired vision, muscæ volitantes, a dragging uneasiness in the region of the liver, torpid bowels, evacuations pale-coloured, urine dark and scanty, a constant feeling of lassitude, every exertion requiring an effort; and, in short, a total loss of energy, passing restless nights, and rising in the morning wholly unrefreshed. Various remedies had been employed, such as blue pill at night, and a purge in the morning; also infusions of calomba, gentian, &c., with and without rhubarb, soda, &c., but without producing any permanent advantage. I then determined to try the effect of sea-water, which I had so often found useful in similar cases. I accordingly commenced its use, taking a full pint each day early in the morning, while still in bed. Its action upon the bowels was speedy and pleasant, generally passing off in a couple of hours; and instead of losing its effect by repetition, it rather acted more freely after a few days' use than it did at first; and although I continued to take it for forty successive days, it lost none of its powers. Before the end of a week the pain and confusion in the head were much mitigated, the appetite certainly better, the urine considerably increased in quantity, and of a natural colour, and the dragging pain in the side alleviated.

At the end of fourteen days the head nearly well, appetite good, and move about with much more alacrity; sleep tranquil; and from this time all the uneasy symptoms gradually disappeared; the alvine secretions became natural, and at the end of six weeks I found myself restored to my usual health and energies.

From this time I began to entertain a higher esteem for the medicinal powers of sea-water, and have tried it upon a more extended scale, and have every reason to be satisfied with the results. I subjoin an analysis, for those who have not before attended to the subject.

Mur. Sodæ	180·5
Mur. Magnes.	18·3
Mur. Calcis	5·7
Sulph. Magnes.......	21·6
	226·1

Iodine and bromine have also been detected in it. These are the relative proportions; and an imperial pint of sea-water contains somewhat more than half an ounce of these salts, subject to some slight variation.

NERVES OF THE TONGUE.

EXPERIMENTS SHOWING THAT THE FUNCTION OF TASTE IS DISTINCT FROM COMMON SENSATION.

To the Editor of the Medical Gazette.

SIR,

BY the favour of Mr. Ker, one of the surgeons to the Ardwick and Ancoats Dispensary, I have been enabled to ascertain some particulars of a case of facial paralysis, leading to the same conclusions, relative to the separateness of the functions of "taste" and "common sensation," as my former communication upon the same subject, which appeared in the Gazette about a year ago.

It may be in the recollection of those of your readers whose attention has been directed to this branch of physiology, that the case of Mrs. Williams, which you did me the honour to publish, manifested the existence of paralysis of sensation in one half of the tongue, whilst taste, on the paralysed side, was in a state of integrity. The case which I am about to detail forms almost the exact counterpart, taste being entirely abolished on one half of the lingual surface, whilst its common sensibility is but slightly impaired.

John Davis, 35 years of age, residing in Ordsall Lane, near the Regent's Road, Salford, was attacked with paralysis of both motion and sensation, in the left half of the head and face, about two years ago. He states that for two or three years prior to this attack he had suffered from pains of a rheumatic character, especially in his head; that the headache was not confined to either hemisphere; that latterly he has not been so much afflicted with these pains; and that, generally speaking, the paralysed condition has gradually improved. He was seen by me for the first and only time a few days ago, and his present condition appears to be as follows:—He complains of no particular pain, and the face is scarcely at all drawn to the right side. On protruding the tongue it is thrust to the right, as though its muscles were paralysed on the side stated not to have hitherto been generally affected; in other respects the right side of the face seems to be in a healthful state. Vision on the left side would appear to be only affected in a very slight degree, since objects, numbers, and characters, are at once recognised, though not with the ordinary distinctness, according to his own statement. The peculiar sensibility to light, which, on its too vivid approach, occasions the consciousness of dazzling, seems lost, as evinced by the absence of any symptom of intolerance, however near the light of a candle may be brought. Hearing, he states, is entirely gone on the affected side; and common sensation, by his own account, is not so complete on the left as on the right side, though, on any trial being made, he at once expresses the ordinary consciousness; and, in more immediate connexion with the object of the present paper, the sense of taste is entirely destroyed on the left half of the tongue, whilst its common feeling is not very notably diminished.

This investigation took place in the presence of Mr. Ker, through whose kindness I had the opportunity of witnessing this very interesting case, and of Mr. Walker, of this town, whose assiduous attention to the physiology of the nervous system is well known to the readers of the Medical Gazette; and these gentlemen concur with me in attestation of the accuracy of the experiments, of which I will now detail those relating especially to the separateness of the functions of *common* and *specific* feeling in the tongue.

The man during their whole progress was blindfolded; and, on protruding the

tongue, a piece of silver was lightly drawn around its margin, and it was at once recognised as a metallic substance, though somewhat more distinctly on the right side. The point of a lancet was gently thrust upon the mucous membrane of the left side, and the sense of pricking was declared to be felt. The corner of a silk pocket handkerchief was brought barely in contact with the margin of the same side, and a light soft substance was said to have been in contact. A silver spoon was placed on the affected half, and he was asked whether it was hot or cold: his reply accorded with the fact; it was rather cold. I applied the extremities of the fingers, and he recognised them, and also as being rather warm.

These trials were considered to be amply sufficient for determining the existence of common feeling, without any material diminution; and the experiments were next directed to ascertaining the condition of the sense of taste. And it may be well to premise, that the tongue was perfectly clean and moist, so as to afford the fairest opportunity for prosecuting the investigation.

Common salt was sprinkled upon the affected half, and allowed to dissolve, but no taste was perceived until it was pressed against the palate, when the salt was recognised, but whether in the palate of the affected side, or not, was difficult to determine, as the man himself considered the recognition to result from the impregnation of the saliva generally with the sapid ingredient. A portion of aloes was applied to the anterior margin of the affected half, and the application was continued for many seconds, but no taste was felt. On the same application being made to the opposite margin, its peculiar flavour was instantaneously perceived and declared. A concentrated preparation of the compound decoction of aloes was applied on each side with similar results; also a concentration of the lac ammoniaci, and the conclusion was the same. Lastly, a drop of the oil of peppermint was allowed to fall on each side, with perfect insensibility of taste on the left, and instantaneous and acute sensation of pungency and aroma on the right side.

These experiments were considered to render it clear that, in this case, whilst the common sensibility of the left half of the tongue is but little impaired, its specific feeling is lost.

I make no *comment*. This case is offered to the profession as an additional *fact*, tending most strongly, in the opinion of the present writer, to the conclusion that the function of taste is not a modification of common sensation; and that, in accordance with all the analogy which physiology affords, we must look for a separate nervous supply.

I am, sir,
Your obedient servant,
DANIEL NOBLE.

Manchester, Nov. 12, 1835.

DISLOCATION OF THE HIP-JOINT,

SUCCESSFULLY TREATED.

To the Editor of the Medical Gazette.

SIR,

I BEG to send you a statement of the treatment of a case of dislocation of the os femoris on the dorsum of the ilium, in corroboration of the utility of keeping up the action of the skin in contusion and laceration of the ligamentous and muscular structures.

September 29th, 1835. — Mr. John A——, aged 22 years, a strong robust farmer, was thrown out of a cart, by which fall he dislocated the hip-joint. After the reduction he was put into bed, and had the joint fomented with hot water at intervals; took a draught composed of two drachms of sulphate of magnesia and half a grain of tartarized antimony in mint-water every three hours; gruel diet.

30th.—The hip swollen and painful, with discoloration; pulse full and frequent; skin hot; tongue white; great thirst.

Abstract fourteen ounces of blood from the arm; continue the fomentation, draughts, and low diet. A mustard cataplasm to be applied on the hip, just over the trochanter major, for half an hour night and morning.

Oct. 1st.—The pain much lessened; the tongue moist. Pulse fallen and regular; bowels have been freely relieved.

Continue the mustard poultices, omit the fomentations, and take the

draughts twice a day, and one tea-cupful of mutton broth in the middle of the day.

2d.—Much improved; can flex the thigh a little. There is scarcely any pain on making pressure on the upper portion of the os femoris.

Ordered an embrocation to be used twice a day, of equal parts of Liq. Ammoniæ and Lin. Saponis, to the region of the hip, and along the outer part of the thigh.

3d.—Still better.

Discontinue the mustard cataplasms, continue the embrocation, and omit the medicine. Increase the diet to four ounces of meat per day. Use gentle flexion and rotation to the limb in bed.

4th, 5th, and 6th. — Gradually increasing the flexion and rotation of the limb.

7th.—Ordered him to get out of bed, and just bear the weight of the body on the injured leg.

8th.—Ordered him to walk three steps.

9th.—Increased the number of steps to twelve. Apply a flannel roller round the hips.

10th.—Still increase the steps.

11th.—He walked down stairs.

12th.—Sat up the whole day, occasionally walking across the room. I now applied a broad belt round the pelvis, which buckled in front by means of three straps, and two others passed under each thigh, so as to prevent it rising over the spines of the ilium; since which time he has been daily gaining strength in the joint, and is now able to walk two or three miles with little or no inconvenience; forty days only having elapsed since the accident.

I remain, sir,
Yours most respectfully,
John Grantham.

Crayford, Kent, Nov. 2, 1835.

ON DISCHARGE OF PUS FROM THE EAR,

AFTER INJURIES OF THE HEAD.

To the Editor of the Medical Gazette.

Sir,

In a recent number you have inserted an account of two cases of abscess of the brain, discharging by the meatus auditorius; in one of which, a patient of Dr. Macleod's, the natural termination of the disease was shown undisturbed, while in the other, a patient of my own, the rapidity of the disease was probably somewhat accelerated by a blow upon the head. They both of them show the comparative freedom from acute inflammation, and the sloughy appearance of the abscess which these cases usually present.

Discharge of pus by the auditory meatus sometimes takes place, however, in another way—viz. when a fracture of the temporal bone has been followed by suppuration between the bone and the dura mater. The two cases which I have sent to you from my hospital note-book are examples of this accident. In the second, dissection showed the manner in which the discharge had taken place through the fracture; and the first is, I presume, an instance of the same injury, for it can hardly be supposed that, in such cases, the discharge can take place by *ulceration* through the bone, as in the more common cases which you formerly related, since it occurs at too early a period after the accident to make such ulceration probable; and every day's experience shows that fractures of the bones of the skull, attended by symptoms of concussion only, are by no means unfrequent, and also, that the petrous portion of the temporal bone is a situation in which fractures are very often produced, especially where a person falls from a height upon the vertex or side of his head, so that the roof of the cavity of the tympanum, which is opened by the fracture, affords a ready exit to the pus, the membrana tympani being either ruptured at the time of the blow, or opened by ulceration at a subsequent period.

The *direction* of the fracture in the second case was obliquely from behind forwards, so that the seventh pair of nerves escaped; but in other cases of the same accident, it is across the base of the skull, implicating the sphænoid bone, and often both temporal bones at once. In such severer injuries, extensive discharge of blood through the meatus, or between the dura mater and the bone, or into the cavity of the cranium, arises from laceration of the lateral sinus; and the hæmorrhage from the ear is accompanied by partial paralysis of the same side of the face, or by

deafness, from injury to the divisions of the seventh nerve, as it lies within the temporal bone. In the first case deafness existed; but it was probably, from its temporary nature, produced by inflammation only, and not by direct injury to the nerve; and perhaps the reason why it was not occasioned in the second case, might have been from the suppuration having taken place *behind* the superior angle of the petrous bone, *i. e.* in connexion with the cerebellum, instead of the more usual situation in front of this angle, and in connexion with the cerebrum; the organ of hearing being nearer to the latter situation than to the former.—I am, sir,

Your obedient servant,
CÆSAR HAWKINS.

31, Half-moon-Street,
Nov. 14, 1835.

CASE I.—*Injury of the Head—Symptoms of Pressure—Discharge from the Meatus.*

James Cook, æt. 14, was admitted into St. George's Hospital, June 4th, 1830, with the following history:—About a month before his admission he fell from a first-floor window upon some loose earth, striking the right side of his head in his fall. He was stunned for ten minutes, and vomited on his recovery, and was confined to his bed three weeks with *acute pain* in the head, during which time he was bled and cupped with relief. Then he walked about apparently well for two or three days, till, on the 31st of May, he was seized with his present symptoms.

He is unable to stand without assistance, and the movements of the legs are staggering and uncertain, so that the legs cross one another, and he would fall down if not supported. He has dimness of sight, wandering of the eyes, dilated pupils, scarcely acting at all when the candle is brought near them, especially the left, which is almost entirely insensible. Severe pain in the forehead; bowels constipated; pulse 108, rather full and sharp; tongue white, but moist. Skin cold on admission, from his ride to the hospital, but soon rather hot and dry.

V.S. ad ℥xj. Appl. Lotio frigida fronti.
℞ Pulv. Ant., Hydr. Submur. aa. gr. iij. M. vespere.
℞ Haust. Sennæ mane.

5th. — Blood not buffed. Bowels opened with difficulty, after a repetition of purgatives, and the evacuations dark-green and offensive. Countenance more calm, and he breathes easily, and says he is better. Pulse 112, soft and compressible; tongue white in the centre, red elsewhere; skin very hot and dry.

Hirud. x. fronti. Enema Oleos. statim.

6th.—No flush, no heat of skin; tongue moist; pulse only 68, but with now and then a double beat, and rather thready; bowels open twice. Pupils not so sluggish, nor so dilated; the left now contracting more than the right, instead of being less influenced by light. He complains much of pain about the right ear, near the seat of the blow, but the general pain of the forehead is gone, and he thinks himself partly deaf on the right side.

℞ Cal. gr. iij. P. Jalapæ, gr. xij. statim.

7th.—Slept well, and has less pain. When taken out of bed he evidently had more power over the legs, though they still crossed one another. Pulse 68, soft and quiet; tongue clean and moist.

H. Sennæ 3tiis horis.

8th.—Empl. Lyttæ nuchæ.

12th. — Considerable difficulty has been experienced in overcoming the torpor of the bowels by repeated purgatives; the evacuations, however, have become more healthy. Symptoms all lessened. Copious *suppuration* from the *right ear*, the pain around which has lessened.

19th.—Rep. Empl. Lyttæ, et appl. vesic. Ung. Hydr. fort.

Discharge from the ear still copious. Bowels continue torpid. Legs stronger, and directed properly, but tottering; pupils somewhat dilated, and still sluggish.

26th.—Rep. Empl. Lyttæ nuchæ, et postia appl. Ung. Sabinæ.

From this time the improvement in his gait steadily continued, and the discharge from the ear lessened, and nothing of consequence was done except his taking for three or four days a grain of calomel twice a day; and on the 20th July he left the hospital quite well, walking as strongly as ever.

CASE II.—*Fracture of the Temporal Bone—Suppuration in the Lateral Sinus—Discharge from the Meatus.*

Philip Burns, æt. 37, was admitted

into St. George's Hospital, July 27th, 1835, soon after the following accident. While scuffling with another man, being intoxicated at the time, he fell on the floor, and struck his head against the edge of a stone step, by which a scalp wound an inch and a half long was inflicted behind the left ear, the bone beneath (the angle of the parietal, just at its junction with the occipital and temporal) being a little denuded. He was said immediately after his fall, while still on the floor, to have had some convulsion like epilepsy.

After his admission he had no symptom of injury of the head, except a little giddiness on the 30th; the wound nearly healed, and he was made an out-patient on the 5th August.

August 27th he was brought to me again, and I re-admitted him into the hospital, at which time he had much irritative fever, with considerable anxiety of countenance, with a weak pulse and cold extremities, as if he had been half-starved, which, indeed, he complained of having been, the tongue being white but moist. It appeared that he had experienced much pain in the head since he left the hospital, and that yesterday considerable *purulent discharge* had taken place from the *left ear*. This still continued; and on examining the wound behind the ear, which was foul, and the edges undermined, the bone was felt exposed, and the probe passed some way into it through the intervals of the suture; and what seemed to be the end of a fissure in the temporal bone joining the suture was also felt.

> Three grains of Calomel and of Antimonial Powder, with one of Opium, were given, and a Senna draught in the morning.

28th.—He slept well, and feels better; the pulse has more power, though without much sharpness. Complains of pain in the head. V. S. ad ℥viij. Blood inflamed; faintness produced.

> ℞ Haust. Salin. ℥iss.; Magn. Sulph. ʒj.; V. Antim. ʒss. M. 6tis horis.

29th.—Had rigor twice last night; slept badly; discharge from the ear increased.

30th.—Was very restless last night, and required an opiate. Pulse weaker. Had one rigor.

31st.—There is now no pain in the head; pulse 80, weak; tongue inclined to have a brown fur; discharge free from the ear; has profuse perspiration following repeated rigors; looks anxious and distressed both in mind and body.

> Omit. H. Salin. Ordered some beef-tea and light nourishment.
>

September 1st.—Less perspiration; no rigor; no pain, and he feels better. No affection of the mind nor of the muscles, except indistinctness of speech from apoplexy two years since.

3d.—A little delirium. Occasional vomiting after food; perspiration continues. He is evidently weaker.

The operation of trephining had been several times agitated since his admission into the hospital, but as the discharge from the ear was quite free, and the exposed bone had not the appearance of having purulent matter below it, and there was an entire absence of symptoms indicating either direct irritation or pressure upon the brain, the operation was not hitherto thought advisable by my colleagues or myself. The symptoms were not those of confined matter connected with the brain, but only of suppuration of a low kind *somewhere*; and the suppuration might, perhaps, be in the lungs or liver, or in some other situation, from secondary deposits, with as much probability as in the head. If the confined matter was situated in the head, it might be *within* the dura mater, with as much or even greater probability than *below* the bone; as what was perhaps formed below the bone in the situation of the injury, appeared to have so ready an exit through the ear. As, however, he was evidently sinking, unless some relief could be afforded, we now thought it better to give him the chance, though small, of some pus below the injured bone not being readily discharged.

The trephine was accordingly applied in the centre of the exposed part of the parietal bone, so as to include the end of the fracture in the temporal, where it reached the suture of the three bones at their junction. The bone, however, was only dead on the surface; it bled freely during the operation, and afterwards, from a large meningeal branch, and the dura mater was perfectly healthy below.

He was, of course, not relieved by the operation. The perspiration continued, with occasional slight delirium;

the tongue became brown, and rather dry. He then had drowsiness and inclination to stupor, though he was capable of answering rationally almost to his death, which occurred in the afternoon of September 6th.

On examination after death, it was found that the aperture made by the trephine included the end of the additamentum suturæ lambdoidalis, and the end of a fracture of the temporal bone, which extended from the suture to the meatus, and across the petrous portion to the junction with the sphænoid bone. The portion removed was the end of the parietal bone, just above the superior angle of the petrous portion of the temporal bone, and was consequently less than a quarter of an inch from the tentorium and the lateral sinus, where the horizontal portion of the latter turns down into the deep fossa of the temporal bone. The dura mater, where exposed by the trephine, and on the upper part of the temporal bone, was quite healthy, but below the level of the tentorium was inflamed, and coated with lymph and pus on both its surfaces. The suppuration seemed to have commenced in the lateral sinus in the temporal fossa, as it was obliterated by coagula of blood, which adhered to its inner surface; and between it and the bone were two small ulcerated openings, while another ulceration had taken place on its internal or cerebral aspect. From this opening matter escaped, so as to cover the neighbouring part of the cerebellum to some extent. Around the external opening more lymph had been effused than around the internal, preventing the separation of the dura mater from the bone to a greater extent; and thence the matter had escaped either along the line of fracture posteriorly into the meatus, or perhaps through the fracture in the roof of the tympanum, from which cavity it made its way suddenly the day before his second admission into the hospital: ulceration having then, perhaps, taken place in the membrane.

EXTRAORDINARY CASE OF ABSTINENCE.

To the Editor of the Medical Gazette.

Sir,

It will give me much pleasure if you find the following case of abstinence for twenty-three days worthy of recording. I hope you will excuse the imperfection of the report, as, owing to the distance, (about seventeen miles), at which the case occurred, and the short time the man survived, I was able to see him only once. I am indebted to the kindness of Drs. Blain and Vass, who were in the more immediate neighbourhood, for many of the particulars; the rest were gathered from the unfortunate man himself and his companions.

I am, sir,
Your obedient servant,
C. F. Sloan, M.D.

Ayre, Nov. 11, 1835.

John Brown, aged 65, of a spare habit of body, and uncommonly vigorous for his time of life, about four o'clock in the morning of the 8th ult., went to his work in the Kilgramie coal-works, Ayrshire. He did not breakfast before leaving home, and had nothing in his pockets except about a quarter of an ounce of tobacco. Shortly after he had commenced work, the alarm was given that the pit was falling in; he unfortunately disregarded the warning, and, alone, of all his companions, was unable to effect his escape. From some circumstances which it is unnecessary to mention here, he was supposed to be not crushed under the ruins, but confined in one of the galleries. This surmise proved correct, and on the 31st of the same month, about 7 A.M., he was discovered alive, having thus existed twenty-three days and some hours without food. The place in which he was shut up was sixty yards long, six feet high, and twelve feet broad. At some distance from where he was found lying there was a collection of water, strongly impregnated with iron. The air was so bad, that the lamps of the workmen were extinguished the moment they entered this gallery; and it was with difficulty, from the giddiness and weakness induced, that they made their way to him, directed by a feeble sound that he emitted. He was quite conscious when found, and on being brought to the light, readily recognized and named his deliverers; his voice was sunk to a whisper; he was so weak as scarcely to be able to approach his hand to his mouth; he was so much emaciated, as to excite the surprise of his fellow workmen by his extreme lightness. His friends gave him some butter, which he seemed to relish very much, and some

milk, which last he asked for himself. So well aware was he of the danger of his situation, that he firmly refused more stimulating food which was offered him. Medical attendance was procured as soon as possible. He was ordered small quantities of soup and wine negus at intervals. His bowels, which were obstinately constipated, were relieved by injections of warm water and soap. Under this treatment he gained strength, and was able, on Sunday, the 1st Nov. to give a distinct account of his sufferings. He stated that for the first two days, according to his calculation, hunger was his most urgent symptom; the tobacco which he chewed relieved this sensation; he had some oil in his lamp, which he did not use, as he had found on a former occasion, when confined for three days under similar circumstances, it had produced sickness. Hunger now passed off, and he began to suffer from severe thirst; this the water mentioned above afforded him the means of allaying. For what he supposed the first ten days, he could walk about, but after that period he became so weak as to be unable to move, and he had unfortunately lain down at some distance from the water. He remained in this situation till discovered. He slept but little, and never soundly, never entirely losing the consciousness of his situation. His bowels acted only once when in the pit, but he made water freely, both during his confinement and after his release.

The stimulant was occasionally changed for porter, sweetened with sugar, and whiskey toddy, both cautiously administered; arrow-root and oatmeal porridge were also given, but in very small quantities, as his appetite seemed entirely gone. The matter brought away by the injections was black, like meconium, and very fœtid. He continued to improve till the evening of Monday, the 2d Nov. when a change for the worse was observed.

The following was his state when I saw him on Tuesday noon:—His features were sharp and pale; his eye sunk; the parietes of the abdomen seemed to touch the back bone, which could be distinctly felt through them; his body generally presented more emaciation than I had ever seen produced by disease: he had altogether a dried appearance, very much like the natural mummies sometimes found in catacombs. His pulse was gone at the wrist; his voice a whisper, resembling the *vox cholerica*; respiration easy; tongue clean, moist at the edges, dry in the centre. He complained of uneasiness, increased by pressure, in the region of the stomach. He had no stools except from injections, which still brought away the black matter before described. His intellect was perfectly sound, and remained so till death. He never vomited, or had nausea. His pulse, on first coming out of the pit, was 60, moderately firm, and never rose much above this till Tuesday, when it rose to 70, but feeble. He was ordered half an ounce of port wine, made into negus, every hour, with a table spoonful or two of soup in the intervals.

He continued to sink, and died at 11 o'clock that night. No inspection of the body could be obtained.

It was scarcely to be expected that Brown could have recovered under any circumstances; though perhaps in an hospital, with a medical man in constant attendance, and the aid of experienced nurses, he might have lingered longer.

This case proves that delirium, so much insisted on by some writers, and particularly by the historian of the wreck of the Medusa frigate, is not a constant result of prolonged abstinence; that there is some truth in the aphorism of Hippocrates, which says, that when a person in health abstains from food for seven days, even though he received nourishment at the end of that period, he never survives; that thirst, not hunger, is the most distressing symptom. It also serves as a warning to workmen, in similar circumstances, not to despair of recovering their companions alive, though a considerable time may have elapsed.

It is possible that the air he respired was more pure than at the spot the workmen entered the gallery, as supposing the passage to slope upwards towards him, there might be a stratum of carbonic acid of some thickness, which, in a distance of sixty yards, would gradually disappear. An atmosphere slightly impure, by lowering the vital powers, might tend to prolong life under privation of food. The blackness of the stools might arise from the quantity of iron in the water he drank.

With regard to his measurement of

time, I may only allude to the power some people possess of estimating the lapse of time unassisted by artificial means.

ON THE

CURE OF PROLAPSUS UTERI.

By G. O. Heming, M.D. Glasg. F.L.S. &c.

The readers of the Medical Gazette will probably remember the case of Prolapsus Uteri which was published in the ninth volume, in November 1831, by Dr. Marshall Hall; and which was effectually cured by an operation which I performed at the suggestion of that gentleman.

This subject has recently occupied the attention of the surgeons in Paris, and several notices have appeared in the Reports of the Proceedings of the Académie Royale de Médecine, and in the Parisian journals, relative to it. I think an account of these discussions cannot fail to interest the members of our profession in England.

The first of these notices of which I shall give an account, is that of two communications made to the Académie on the 11th of August: one by M. Velpeau, the other by M. Bérard, jun.*

"M. Velpeau communicated the case of a woman, about fifty years of age, who had for a long time been affected with prolapsus uteri. There was also cystocele, pushing the uterus backwards. An operation was performed, according to the plan of MM. Marshall Hall, Heming, and Ireland, though with the following modifications:—In order to effect a considerable tightening, three shreds of the mucous membrane of the vagina were removed—one anterior, the other two lateral, beginning at the os externum; each of these shreds was ten lines in breadth, and two inches and a half in length. A difficulty is usually found, after removing the shreds, in making the suture. M. Velpeau took the precaution to fix the thread previously. The operation was not attended with any untoward event; the hæmorrhage and pain were very slight, and cicatrization ensued by the first intention. Some colic pains, arising from the retention of some fæcal matters, were subdued by laxative medicines. The patient was cured two months ago, and the cure promises to be permanent. The operation is at once free from pain or inconvenience, and appears most effectual. M. Maingault objected, that, in the case of young women, likely to become mothers, this operation would involve serious inconveniences. M. Velpeau observed, that this objection might appear well-founded at first sight, but that there were facts to shew that cicatrices of the vagina may yield sufficiently during labours to admit of the passage of the fœtus. M. Bérard, jun. related the case of a woman, in which he performed the same operation with entire success. Out of three instances, in which he had himself been the operator, two persons were completely cured."

Since that day, M. Bérard has repeated the same operation. He proposes to designate it by the term "Elytroraphie."

To this brief account of the proceedings of the Académie, I beg to add that of a Clinique by M. Velpeau, published by Dr. Dufresse, in the Journal Hebdomadaire, for August the 29th, tom. iii. No. 35, p. 275:—

"There came under my care (says the Professor) a woman, aged 58, of dark complexion and well formed, affected with prolapsus uteri to such a degree that this organ projected through the os externum. The cervix was neither inflamed nor ulcerated. The patient experienced no pain, and she could reduce the tumor herself.

This affection is rather an infirmity than a disease. It may, however, become a source of serious disease, in consequence of the dragging which is produced by it on the parts contained within the pelvis. It may also be the cause of peritonitis, inflammation of the cellular membrane of the pelvis, and consequently of abscess; and the intestines may be drawn into the *cul de sac* which is thus formed. It may also be the cause of strangulated hernia; and, lastly, of ulceration of the neck of the uterus.

The surgical means which have been hitherto employed are only palliative. They consist of pessaries, by the use of which the patient is subjected to numerous accidents. There is considerable variety in the form of these pessaries;

---

* Archives Générales, tom. viii. Series ii.

some are oval, others elliptical, or "en gimblette." They are with difficulty retained in their proper situation, and are ill calculated to support the uterus. They imbed themselves deeply in the parietes of the vagina, and produce inflammation; in consequence of which it is frequently necessary to withdraw them. Others have the form of a "bilboquet." It has a stem, which projects out of the vagina, and produces much inconvenience when the patient sits down. This is often broken, and then the cup remains in the vagina, where it becomes covered with a calcareous concretion. Pessaries have also been known to perforate the recto-vaginal septum, and the sores thus produced to become fistulous. There are, besides, "pessaires élytroides." These are with difficulty kept in the vagina.

The insufficiency, then, of these means, and the inconveniences which follow their application, justify the efforts which have been made to obtain a radical cure; which has been effected in some cases.

There is one principle only, but this is effected in various ways. It has been founded upon that which is adopted for the cure of prolapsus ani. This consists in contracting the orifice of the anus to a greater or less extent. Hey was the first to adopt it in England, but M. Dupuytren, in France, described it with much more accuracy, and ought justly to be considered as the first who gave rules for its performance. Thus, from the success obtained in cases of prolapsus ani, it has led to a belief that the same benefit might be expected in cases of prolapsus uteri, by contracting the vagina.

The first idea of this operation is due to M. Girardin, who described it in a memoir which he presented to the *Société de Médecine de Metz* or *de Nancy*. He proposed to contract the vagina, and, if necessary, even completely to obliterate it, in women in whom the catamenia had ceased. He found many opponents to his ideas, which were rejected. The manuscript remains unpublished, the journal of the society having given only an analysis of it, which I have now before me.

These ideas have since been renewed, reduced to rules, and adopted with success. M. Dieffenbach, of Berlin, has employed this method. In 1831 many of our young surgeons went into Poland, and they addressed letters to the *Gazette Médicale*, in which they give an account of many cases of procidentia uteri, in which there had been performed an operation similar to that adopted by M. Dupuytren for the cure of prolapsus ani.

Two years ago M. Laugier tried to cure a case of prolapsus uteri which came under his care, by contracting the vagina. I believe this case has not been published.

M. Tanchou was acquainted with this method, but kept it a secret. He has published nothing upon it; he has only put in his claim against that of the English surgeons, who wish to consider the priority in reference to this operation as due to themselves.

M. Dieffenbach is contented with removing the folds of the vagina near the inferior orifice.

M. Laugier cauterized a broad strip of the mucous membrane with the nitrate of mercury.

MM. Marshall Hall, Heming, and Ireland, in England, have performed the operation with complete success. Their method consists in removing an elliptical shred of the mucous membrane from the internal surface of the vagina, an inch in breadth, and several inches in length. The wound is then united by the interrupted suture. In some cases two such shreds have been removed, one from the left, and the other from the right side.

In the case which I have described, the catamenia had subsided for a long time. The uterus projected two inches externally; the tissues were not hypertrophied, nor had they undergone any other alteration of structure.

The plan which we propose is as follows:—First to remove the anterior column of the vagina from the inferior part to the superior, before reducing the prolapsus; then to reduce it, and remove from the lateral parts of the vagina, both right and left, and along the whole length of this canal, a band of the mucous membrane; and, lastly, to unite the anterior wound by the interrupted suture.

In our opinion it is much better, when the procidentia is not very considerable, to insert the sutures before removing the anterior shred of mucous membrane, so that the threads may be situated about a line from the edges of the wound. We advise this to be done

in consequence of the pain causing the parts to contract, when the excision is made before the sutures are inserted; and in many cases when this happens it is exceedingly difficult to insert them. In the dissection of the anterior shred considerable caution is necessary lest the vesico-vaginal septum be completely cut through.

The woman who forms the subject of this communication experienced no inconvenience; and some days since she walked in the wards of the hospital, and in the gardens, without the least tendency to a return of the prolapsus. We may now, therefore, calculate upon almost certain success by an operation."

What I have to add is a little amusing. It seems M. Girardin has written to the "Académie," to remind its members that in 1822 he had proposed to cure prolapsus uteri. It is added that M. Girardin "a voulu par cette communication assurer à l'opération son origine, et maintenir à la *Chirurgie Française (!)* la priorité de l'invention, sinon de son execution*."

It seems that the profession in France remained steady in their opposition to this measure, and that M. Girardin slept upon his mere proposition. I do not imagine, therefore, that either will gain much by any attempt to deprive Dr. Marshall Hall and myself of whatever merit there may be in having both *devised and executed* this simple, almost painless, almost bloodless, yet important operation. To compare our operation to that of Hey, or that of Dupuytren, for prolapsus ani; or to those of M. Dieffenbach and M. Langier, for prolapsus uteri, neither of which *could* succeed, is equally futile. As to M. Tanchou, who could keep his mode of proceeding secret, he does not deserve a moment's notice.

I hope soon to transmit some other cases, with remarks upon the best mode of performing this operation, and upon the circumstances of age, &c. by which it might appear to be limited.

Without attaching too much importance to it, I cannot but regard this operation as a valuable addition to our curative means. Prolapsus uteri is frequently a great calamity. The mode of cure proposed is at once effectual, and free from either pain or danger if properly performed.

Manchester-Square,

CASE OF HYDROPHOBIA;

WITH REMARKS.

To the Editor of the Medical Gazette.

SIR,

AMONG the various diseases incident to the human body, there is none more distressing and formidable in its aspect, or that more perplexes the skill and arouses the sympathy of the medical practitioner, than hydrophobia. In the present state of our knowledge it appears to be so obscured by difficulties, that the question very naturally suggests itself whether our opinions regarding the subject be correctly formed or not; and inasmuch as it proves so rapidly fatal in the majority of instances, it is deeply to be deplored by all that the malady is so little under the control of remedial art.

It is a most singular circumstance that the poison which becomes inoculated by the bite of a rabid creature should not, like other animal poisons, produce an almost immediate effect upon the constitution; but that the virus, on the contrary, should lurk in the system, and not give rise to the direful symptoms until the wounds themselves had fully healed, and the patient had banished from his mind all fear of danger. Such, however, is the fact; and it is not unreasonable to inquire how the virus acts so as ultimately to be the means of destroying life. *Is the matter taken up by the absorbent vessels, or does it exert its fatal influence through the medium of the sentient extremities of the nervous filaments?* The principles upon which each practitioner philosophises, and by which he is guided in the use or application of remedies, must depend upon the view which he takes with respect to the *modus operandi* of the poison; and this, in my humble opinion, satisfactorily accounts for the diversified methods of treatment which have been adopted by different practitioners. Upon a rational solution of the inquiry just now proposed, a subject of intense interest and importance hangs suspended.

The following case having lately occurred in my practice, I have forwarded it to the Gazette, not so much with a view of placing it on record, as with the hope of eliciting information relative to these points from some of the more ex-

perienced members of the profession. During the continuance of the case, it excited feelings of most painful interest; and I was excessively disappointed when the result proved the total inefficiency of the means employed, because I had every reason to believe that at one time they were signally beneficial in alleviating, if not in arresting, the progress of the more violent symptoms. It will be seen that, in consequence of the lacerated state of the limb, and the proximity of the wounds to the tendo Achillis, excision could not be performed to the extent usually recommended, without rendering the patient for ever a cripple; and the operation did not seem imperatively required, as the accident was generally attributed to the boy's having struck the dog upon the mouth while suffering from the effects of severe wounds. Had there been more unequivocal marks of the animal being rabid, I should at once have proposed amputation, as being the only means of ensuring life; and the issue has convinced me that such a measure would have been altogether unjustifiable. But the father of the boy was so satisfied that the dog was not in the state to which I have alluded, that he was led to express great anger that he was so cruelly destroyed.

Before concluding these remarks, I should like to inquire whether any of your readers are acquainted with *well-authenticated cases* of cure by excision when hydrophobia had *fully* made its appearance; and how far I should have been justified in resorting to amputation after my patient had manifested all the symptoms of this most dreadful malady.

With every wish for the continued prosperity of your journal, permit me to subscribe myself,

Your obedient servant, and
constant reader,
CHARLES THORNHILL.

Darlaston, Staffordshire,
Nov. 13, 1835.

Edward Lloyd, ætatis nearly 11, was bitten, on the 16th of June, by a dog, which was supposed by some to be rabid. The dog belonged to the father of the child, and was usually of quiet disposition. He had been fighting the previous day with a badger, and during the contest had received several severe wounds about the head and neck, from which he recovered with difficulty. He had always been allowed to run at large, and up to the day of the fight was attached to the different members of the family; but on the morning of the accident he was observed to be rather irascible, and to snap at the various articles of furniture that were arranged about the house. In the afternoon, whilst the little boy was sitting at the kitchen door nursing his infant sister, the dog advanced towards the threshold, and on entering the house, stopped to lick the face of the young child. The boy, fearful of consequences, motioned him off, and in so doing, hit him upon one of his recent sores; this so infuriated the animal, that he turned upon and seized him by the leg, which he shook and lacerated in the most shocking manner. When driven off, the dog took shelter in the house; but being compelled to quit his retreat, he ran out and scampered across the fields. He was, however, quickly pursued by the neighbours, and in the course of half an hour was dispatched by a gun-shot.

Two hours after the accident, I was requested to see the boy. The leg was literally covered with wounds, both before and behind; but the principal bites were at the lower part of the calf. A portion of the tendo-Achillis was laid bare, and that part of the gastrocnemius muscle in connexion with it was very much torn. Several loose fragments of muscle were hanging about the leg, and the wounds in general presented a ragged appearance. After freeing them of all adventitious portions, and excising them where it could be done with propriety, I dressed them very freely with the nitrate of silver, covered them with digestive ointment, and strapped them over with adhesive plaister. The dressings were changed every day. The sloughs produced from the application of the caustic were considerable. The caustic was reapplied on several subsequent occasions. The wounds healed kindly; and at the expiration of five weeks the leg was perfectly free from sore.

From the time of the accident to within a few days of the occurrence of the fatal malady, the patient continued to enjoy himself in the fields about home, and seemed fond of frequenting the banks of the canal, where at times he was engaged in fishing for hours together. I have since learnt from his mother that he had recently bathed in the canal, and whilst therein, was seized with a peculiar constriction of the throat, which occasionally returned for some days afterwards. My brother met him in the fields on the 4th of September, when he appeared to walk lame on the leg which had been bitten; and as we had not seen him for more than a week, he was desired to walk up to the surgery the following

morning. His mother came with him, and stated that he had been rather heavy and sleepy during the last day or two, and that his appetite had become more capricious than ordinary. The boy did not appear so lively as usual, and complained of slight pain in his leg, but as yet the symptoms were not sufficient to excite alarm or apprehension in the minds of his relatives. I, however, ordered him as follows:—

℞ Hydrar. Submur. gr. iij.; Pulv. Scammoniæ, gr. iv.; Pulv. Jalapii, gr. vi. Misce. Fiat pulvis. Statim sumendus.

℞ Ammon. Carbon. ℈ij.; Sodæ Carbon. ℈iv.; Confect. Aromat. ʒss.; Misturæ Camphoræ, ℥vj. M. Capiat cochlearia duo 4ta quâque horâ.

11 P.M.—A message was sent to request my attendance. I was engaged at a midwifery case at some distance from home, but my brother went immediately to see him, and called to communicate with me on his return. The boy had been delirious for some hours, and had been attacked with tetanic twitchings during sleep. The mouth was fast locked, the hands were clenched, and his arms tossed about with great vehemence. He had complained of severe pain across the forehead, but his mother had firmly bound a handkerchief round the temples, which afforded a speedy relief. The following was prescribed:—

℞ Pulv. Opii, gr. vj.; Hydrar. Submur. ʒss.; Confect. Rosæ. Caninæ.
Pil. vj. Capiat i. omni horâ.

Being liberated between three and four o'clock on the morning of the 6th, I hastened to visit him in company with my brother. The boy was much agitated on hearing us go up stairs. On our entrance into the room he fetched a heavy sigh, and attempted to hide his face underneath the bed-clothes; at the same time a convulsive motion took place in the upper part of the body, and particularly about the neck and throat. The countenance was distrustful, and indicative of great anxiety and distress. The eyes were much sunk, and perpetually rotating in their sockets, while both pupils were dilated almost to their fullest extent. A little frothy saliva was discharging itself at each angle of the mouth; and the tongue, *which was protruded with a sudden jerk*, was white, and covered with a viscid tenacious mucus. The breathing was hurried, and the inspirations were remarkably quick and short. The pulse was weak, and beating at about 75 in the minute.

It was with the greatest difficulty that I could get him ro respond to any question; for the attempt to speak occasioned him to make a deep sigh, which produced a recurrence of the spasms. On suggesting that he should swallow a little water, he seemed to be frightened, and began to cry out. He turned suddenly in bed, and was simultaneously seized with a momentary clonic spasm of the trunk, greatly resembling *emprosthotonos*; however, by kindly encouraging him, he soon manifested a willingness to accede to my wish; but the sound of the water, as it was poured into a tea-cup, again brought on a similar convulsive action. The very sight or mention of water appeared to excite uneasiness. At length, by putting a little into a spoon, he raised himself up to drink it; but when he had received it into his mouth he was unable to swallow it, as spasm came on, and obliged him to expel it from his mouth to a considerable distance. With difficulty he managed to swallow a small pill in my presence. His hands and arms were copiously bedewed with a cold clammy moisture; but the heat in other parts of the body was not reduced below the natural standard.

On interrogating the mother, I found that the first circumstance which attracted her notice was his repugnance to the sight of water. Having occasion to wash the kitchen on the previous evening, she carried in a pail of water for that purpose, when he was attacked with spasms and convulsive sobbings. As these symptoms did not cross her mind as being of an urgent nature (for they disappeared as soon as the water was removed), she did not deem it necessary to apply for assistance; nor did she feel the slightest alarm until he had become delirious and ungovernable. I also learnt that, on his return home from my surgery, he called at a house to get a little water, but on placing it to his lips he found that he could not drink it.

The pills were ordered to be continued every hour, and the following embrocation to be freely rubbed upon the neck and chest on each recurrence of the spasms:—

℞ Ung. Hydrargyri, ℥iij.; Tinct. Opii, ʒv.; Linim. Saponis, ℥j. M. ft. embrocatio.

9 A.M.—Symptoms much the same as at the last visit. His abdomen was distended, and somewhat tense; he was perfectly sensible and rational, but the head was heated, and wet with perspiration. He showed an unwillingness to submit to the employment of friction, and threw himself about in the most violent manner, sometimes tossing back his head against the bed-board, and at others enveloping himself in the bed-clothes. At every motion he was seized with convulsive twitchings. For some time he strongly resisted every effort that we made to keep him quiet; but

after being assured that he would not be requested to swallow any liquid, he at length yielded, and allowed himself to be rubbed with the liniment.

11 A.M.—Convulsions not so strong as at the last visit; countenance not so wild, and less expressive of pain and distress. Pupils less dilated. He was fully alive to every thing that was going on in the different parts of the chamber; the sense of hearing was morbidly acute, and the slightest noise or movement of any kind made him restless. When questioned he complained of no settled pain; but on pressing gently with my finger upon the upper part of the trachea, pain was produced, and spasms of the neck simultaneously occurred. He was not so much agitated as heretofore at the sight of water; and, on making the attempt, was enabled to swallow nearly a tea-spoonful at a time, though it required considerable effort, and was attended with an involuntary inspiration and spasm. When water was put to his lips he was amazingly eager to partake of it; but in drawing it hurriedly into his mouth, the face became contorted, and the head was drawn back to some distance.

Rep. Embrocatio.

3 P.M.—The spasmodic action of the muscles has not been near so violent or frequent since the friction has been regularly employed; and the patient states that he feels himself much better. His countenance brightened up when he saw me approach his bed-side, but still it is wild and unnatural. His tongue is moist, and stained by some kind of preserve which he has been eating. For the last three hours his thirst has been excessive; and during this time he has drunk, in small quantities frequently administered, at least a pint of toast and water. He is evidently under the influence of the opiate which has been so freely exhibited; and the tetanic symptoms have been materially diminishing for some time.

Having some professional engagements during the remainder of the afternoon, and the patient residing rather more than a mile from me, I was not enabled to visit him again until between six and seven o'clock, when, to my great astonishment, I ascertained that he had been dead nearly half an hour.

It appeared from the account which I obtained, that at about four o'clock the convulsions returned with redoubled violence, during which he made frequent attempts to injure himself; and, to use the remark of one of the attendants, "if he had not been held down by two or three of those who were about him, he would have torn himself to pieces." After having continued in this state for about an hour, he sunk exhausted upon the bed; nor did he move from the position which he had assumed until death released him from his sufferings.

It was much to be regretted that a post-mortem could not be obtained.

ON THE NATURE OF THE NERVOUS INFLUENCE;

IN REPLY TO THE OBSERVATIONS OF DR. WILLIAMS,

In the last Number of the Medical Gazette.

To the Editor of the Medical Gazette.

SIR,

I THINK Dr. Williams will, on reflection, admit that a reference to the opinions of others is no reply to a position which professes to be a legitimate inference from acknowledged facts.

In the first part of his reply, Dr. Williams refers to the observation of Dr. Alison, that "the province of the nervous system in producing the phenomena of life, was more accurately understood by Haller" than in the present day. Do we not at present possess all the knowledge of Haller, with whatever has since been obtained in addition to it? And in the immediately preceding part of the same sentence, Dr. Alison is directly contradicted by Dr. Williams himself; who observes that no one denies that succeeding experimental researches "have greatly increased the precision and extent of our knowledge in these matters."

Dr. Williams then enumerates the opinions of various writers, which can be of no avail in the question before us. The facts and the reasoning founded on them are placed before him. His reply, to have any weight, must either disprove the facts, or point out in what respect the reasoning is fallacious. Whatever relates not to one of these heads, tends only to obscure the truth, and therefore increase our difficulties. The question is not what opinions have prevailed, but what is the true opinion; a point not to be determined by authority, or the majority of voices.

With regard to what Dr. Williams says respecting the diminution of temperature produced by destroying portions of the spinal marrow, depending on an effect produced on the circulation, it appears from M. Le Gallois' experi-

ments, and still more fully from experiments detailed in my Inquiry into the Laws of the Vital Functions, that the gradual destruction, whether of a part or the whole of the spinal marrow, the mode adopted in the experiments I refer to, produces no effect whatever on the circulation. "The only apparent effect of the operation," that is, of destroying the lower half of the spinal marrow, "was the loss of power and feeling in the lower part of the animal: it seemed to be otherwise in health." (Page 138, third edit.) It is only by the sudden destruction of this organ that the circulation is affected: the cause of which it is not difficult to explain.

The great peculiarity in the functions of the ganglionic nerves is, that each nerve, in consequence of its connexion with a chain of ganglions, which receives nerves from every part of the brain and spinal marrow, conveys the influence of every part of those organs, which it appears from direct experiment, is necessary to the healthy state of the assimilating functions in every part of the system. Hence it is that an effect produced on any minute part of these organs, is too trifling to be in the least degree felt, either in the circulation or any other of those functions. I found that the most powerful agent which could be applied to a minute part, either of the brain or spinal marrow, had no sensible effect either on the heart or vessels; while the slightest cause affecting any considerable portion of them, not only influenced the action of the heart but that of the capillary vessels also, even in the remotest parts of the system.

Now when any considerable portion of the brain or spinal marrow is suddenly destroyed, the cause at once affecting a large portion of these organs, the action of the heart and vessels is influenced in proportion to the extent of the part destroyed; and if the whole brain or spinal marrow be thus destroyed, it instantly ceases. But if either of those organs be even wholly destroyed very slowly, so that the offending cause acts on minute parts in slow succession, no effect whatever is produced in the action either of the heart or capillaries. The effect is then the same as when the brain and spinal marrow are simply removed, which produces no effect whatever on the circulation.

It was farther ascertained that the power of the capillary vessels has no dependence on that of the heart, but for a supply of blood. Till the supply of blood from the larger arteries begins to fail, which is not for a considerable time, the action of the capillaries remains unimpaired even in the newly dead animal, provided its death has been occasioned neither by loss of blood, nor a cause which suddenly destroys the brain or spinal marrow, although a ligature be thrown round all the vessels attached to the heart, and this organ removed.

With regard to the effect on the temperature, of bruising the semilunar ganglion, or throwing a ligature round the aorta, it could easily have been foretold that either would greatly impair it: because the one deprives the blood of a great part of the nervous influence, by the action of which on this fluid animal temperature is maintained, and the other prevents the due supply of the blood itself; and with regard to the blood, even out of the body, still for a short time in some degree possessing the power of maintaining its temperature—that is, while its vitality and the influence it has derived from the nervous system remain, and a supply of oxygen is afforded: this also is only what we are prepared to expect from every thing we know of the cause of animal temperature.

The researches of Dr. Faraday enable us to place the question respecting the nature of the nervous influence in a very simple point of view. If we deny that the nervous influence is a modification of electricity, we must either maintain that the chemistry of the living animal depends on a principle altogether different from that of inanimate nature; for example, that the principle on which depends the combination of oxygen and carbon in the blood, is altogether of a different nature from that on which the same combination depends in the laboratory of the chemist, although the resulting substance is in both instances the same; an opinion which, I think, Dr. Williams will allow to be too extravagant even for the most visionary; or we must refute the electro-chemical doctrine of Dr. Faraday, according to which, chemical changes are necessarily the effect of electric action; which will not be found an easy task.

How strikingly is this simple statement illustrated by the experiments which prove that all the functions of the nervous influence, many of which are of a complicated nature, may be as effectually performed by voltaic electricity, operating under the same circumstances in which the nervous influence operates, as by that influence itself, and that this influence can be made to pass through other conductors than the nerves. Experiments the results of which will hardly be questioned, when it is stated that they were publicly repeated, both in London and Paris, and witnessed, and their accuracy admitted, by Sir Humphry Davy, Mr. Andrew Knight, Sir Benjamin Brodie, MM. Breschet and Edwards, and others of the most accurate physiologists of our day.

Is there any physiologist so hardy as to maintain that a vital principle, properly so called, can exist in any texture but that to which it belongs in the living animal; or that, in its functions, any of the powers of inanimate nature can be substituted for it?

Shall we admit that voltaic electricity can perform all the functions of the nervous influence, and yet maintain that the two principles are of a different nature; while, at the same time, we allow that we have no knowledge of any principle of action but by its properties?—for what I have said on this subject we shall find is admitted by Dr. Williams.

The more successfully we study the operations of nature, the more their simplicity appears. In what instance do we find the same phenomena originating from different principles? Nay, do we not find the most dissimilar phenomena originating from modifications of the same principle? What error of reasoning can be greater than to maintain that the properties being the same, the principles are different?

The only difficulty here, has arisen from our having confounded the sensorial and nervous functions. The moment they are distinguished, all difficulty disappears. The nervous functions, properly so called, although modified by the vital principle, are all more or less of the same nature with those effected by electricity in the inanimate world: they are all evidently the effects of a chemical agent.

PHYSIOLOGY is much indebted to those who have shewn that the nerves of motion and those of sensation, although often inclosed in the same sheath, have different origins.

It is evident that the ganglionic nerves differ from both these classes of nerves, their most evident characteristics being their connexion with the ganglions, and their being more peculiarly the nerves of the vital organs; to the whole of which, it appears from experiment, where the parts are too minute for the labours of the anatomist, they are distributed. It will tend to elucidate what has been said in the present communication, to enter more minutely into the nature of these different classes of nerves. Without this, indeed, it is impossible to have a clear view of the whole line of distinction between the sensorial and nervous functions.

It appears from what is said above, that each of the ganglionic nerves, after they leave the chain of ganglions, conveys the influence of every part of the brain and spinal marrow. This is the distinguishing property between these nerves and the two former classes of nerves, the influence conveyed by each of which, were it not for too much prolonging this communication, it would be easy to show has relation only to particular parts of the brain and spinal marrow. But the question which is of most consequence to the practical physician, is the nature of the influence conveyed by these different classes of nerves.

From the foregoing statements the conclusion appears unavoidable, that the influence conveyed by the nerves of motion and the ganglionic nerves is voltaic electricity; and we know from the phenomena of electric animals, that the nervous system is capable of collecting and applying, even according to the dictates of the will, the electric power.

Now let us try by the same test, the only one by which it can be tried, the nature of the influence conveyed by the nerves of sensation.

What are the properties of the influence conveyed by this class of nerves?

It is necessary, in order clearly to understand the answer to this question, to observe, that the nerves of sensation, (in which are included, of course, the nerves of the external organs of the senses) and those parts which are the imme-

diate organs of the sensorium, are not parts of a whole, but distinct parts; for they have distinct localities, and functions of a wholly different nature; that is, the sensorium does not pervade the whole system, but belongs to particular parts. In man these parts are almost wholly confined to the brain, sensations being referred to particular parts of the body by experience alone; so that infants are not aware of the part of the body in which the cause of any particular sensation originates; and when a limb has been lost, at whatever part the separation is made, we still continue to refer to the lost part sensations excited by causes affecting the nerves of the stump.

The following points, then, are made out from the phenomena of every day's experience, that the organs of the sensorial powers, and the nerves of sensation, are distinct parts; the former being the immediate organs of these powers, the latter the organs which convey the influence which excites them.

We have seen that the influence which excites the muscles and maintains all the assimilating functions is an influence which operates in the external world.

Are the properties of the influence conveyed by the nerves of sensation the same with those of any of the principles which operate in that world?

It is enough to say that the only property of this influence is its co-operation with the immediate organs of the sensorial power. To such a property we find nothing analogous in inanimate nature. The nerves of sensation, therefore, belong to the sensorial, not the nervous power; and the only analogy which can be traced between their function and the operations of inanimate nature, is in that property, by which the impression they receive is propagated along them, — a property which they owe to their capability of being excited by agents belonging to inanimate nature, and to which we are indebted for all our knowledge of the external world. The action of the immediate organs of the sensorial power, on the other hand, being excited by one vital part acting on another, and by its vital properties alone, all analogy with inanimate nature here disappears.

While all the other functions are the results of inanimate agents acting on vital parts, or vital parts on them, the sensorial functions are the effects of vital parts acting on each other. Hence the analogy between the former and the operations of inanimate nature, and, with the exception just pointed out, the total loss of all such analogy in the latter.

The foregoing statements being satisfactory to my own mind, and to the minds of those with whom I would not presume to compare myself, I have no doubt that time, as in other similar cases, will remove the confusion which has arisen from the hasty opinions of those whose prepossessions, and in many instances whose habits, but ill prepare them for the consideration of such a question; and here, unless Dr. Williams should adopt very different grounds, I leave the discussion*.

I am happy to observe that Dr. Williams and myself are agreed respecting the second part of my last communication, but with regard to the quotation he, in the latter part of his present reply, gives from that communication, he will recollect that I have explained what I mean by a knowledge of the nature of any principle — namely, a knowledge of its properties; and that we cannot, in this sense, say that we are ignorant of the nature of vitality.

I am, sir,
Your obedient servant,
A. P. W. Philip.

Cavendish Square,
Nov. 17, 1835.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'Alembert.

An Inquiry, Physiological and Pathological, into the Proximate Cause of Cholera. By Protheroe Smith, Member of the Royal College of Surgeons, &c.

There was a time, and that not so very long ago, when books, tracts, pamphlets, and broadsides, on cholera, came upon us thick as the leaves in Vallombrosa. The case is altered: an essay on that well-discussed subject has now

* From a passage in an early part of Dr. Williams's paper, he appears to think that an expression in my last paper was meant to apply to him. I can assure him that this was so far from being the case, that if I had conceived that such an idea could have occurred, I should have worded it in such a manner as to render so unjust an application impossible. I spoke only of general and natural biases of the mind, as I do in the paragraph to which this note is appended.

become as rare as green peas at Christmas. Whether it has happened that publishers have grown tired of the speculation, or authors found themselves run dry, we know not; but we rather congratulated ourselves that nothing in the shape of cholera—either the disease itself, or books about it—visited us of late. Yet when the present pamphlet came upon us, a few days since, we had the curiosity to look into it, and were glad to find that it had much more than its mere rarity to recommend it. There is a good deal of merit and ingenuity in the author's attempt to ascertain the "proximate cause:" he describes what he himself witnessed, and even experienced in his own person; and he proves sufficiently that his opportunities of observation were not misapplied.

As far as we can gather from a hasty perusal, the "proximate cause" of cholera, according to Mr. P. Smith, consists chiefly in the state of the nervous centres: the symptoms, almost from the very setting in of the disorder, may, he thinks, be traced to the reaction consequent upon a strong impression made at an early period on the nervous system. In accordance with this theory, the several stages of the disease are pourtrayed, and cases adduced which tend strongly to support the author's views.

The cases given in the pamphlet have a more than ordinary interest, owing to the fact of their being among the first—one of them said to be the very first—that appeared within the walls of London: so that even in a historical point of view, the author acted judiciously in preserving his notes, and laying them before the public.

MEDICAL GAZETTE.

Saturday, November 21, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

PAUPER POLICY OF THE LEGISLATURE.

MR. BUCHANAN, his Majesty's Consul at New York, not long since broached a project, which, were it put in execution, would spare certain functionaries a deal of trouble, for which they are not peculiarly fitted, and the public generally not a little annoyance and vexation. He proposed that a depôt should be formed in Upper Canada, where the whole pauper population of England might be disposed of. The worthy Consul was serious, and full of benevolence towards his poorer fellow-men; he had no intention whatever of making them any thing but comfortable by the change. His plan may seem at the first view harsh and summary; but surely if the "be-all and end-all" of legislation about the matter be the cheap and humane disposal of the pauper class, it were a thousand times better they were deposited in the wastes of Canada, than pinched and ground down to the starvation point by Poor-Law Commissioners, the very tenure and condition of whose office is, that they should "save to the greatest possible extent in the expenditure on the wants of the poor."

How long will the legislature of the country be guided by this "penny wise and pound foolish" policy in matters of so momentous a nature? for to them we must attribute such a blind and unwise proceeding, when we find them intrusting the fullest discretionary powers regarding the lives of his Majesty's poorer subjects to men who, utterly regardless, or incapable of looking around them, cannot see that there are circumstances in which even an *increase* of expenditure might not only be just to the sufferers, but *ultimately beneficial* to the community.

Our valued correspondent RURICOLA, in his letter last week, set this subject in a clear light; and we are happy to introduce him again to our readers in the present number, following out some of his details.

He stated in his former letter some

facts which are deeply deserving of attention. The extent to which medical men are employed among paupers, throughout the parishes of England, and the treatment which they receive in return, would scarcely be credible, were it not vouched for by so well-informed a writer. Above *a million* cases of sickness annually pass through the hands of the medical attendants of the poor; and what do our professional brethren earn by such ample occupation? Only the scorn, we fear, and the contempt, of the Poor-Law functionaries. " The *parish doctor*, exposed to the summer's sun and winter's blast, toiling by night and day, on a pittance that a footboy would spurn, appears to be as fair an object of their animadversion—perhaps I may add," says Ruricola, " their unwarrantable vituperation—as the overseer who was accustomed to pay his own bills from the rates, or the able-bodied impostor who bullied the frightened farmer into a handsome weekly allowance for doing nothing."

In such a state of things it is clearly hopeless to expect redress, except through the interference of Parliament, and that chiefly by a legislative measure, fixing the remuneration of parish medical officers. The system of *contracting* for medical attendance, and of procuring through " tender" a set of needy adventurers to undertake the charge of the sick through large and densely-peopled districts, must be abandoned, as unjust to the unfortunate poor, and degrading to the respectability of the profession. But how is this desirable consummation to be effected? To hope for a spontaneous change from the functionaries who have doggedly persevered in their plans, were weakness and rashness in the extreme. The co-operation of the profession at large throughout the country affords the only prospect of effectual remedy; while the method of exposure (through the aid of the press), of the actual working of the system, cannot but be productive of much good. We also anticipate important results from the formation of the Committee which we announced a few weeks ago. The answers to the queries proposed by that body, will, we doubt not, contain a mass of evidence, the weight of which, we hope, will be irresistible.

Meantime facts of a deplorable nature are daily being brought before the public, illustrative of the blessings of the new legislation. Even as we write, a letter appears in the *Times* newspaper (November 18th), detailing a case of crying hardship. The author of the letter gives his name—Mr. Hempson Denham, of Wickam-Market, Suffolk: we extract some of the details. The circumstances took place at Petistree. On the 5th instant (Thursday), a poor child was taken ill; and not getting better, the mother on the 8th (Sunday) applied to the gentleman who had been parish-surgeon previous to the passing of the Poor-Law Amendment Act. He gave her some medicine, but mentioned, that as he was no longer parish-surgeon, she would have to apply to Mr. Welton, of Woodbridge, who had obtained the appointment. On the following morning, (Monday,) the father of the child applied to Mr. Walker, the guardian of the parish, but was told, at first, that no assistance could be given, as he was not on the parish books: ultimately, however (but not till another day was lost), he was referred to the *relieving officer*, who lived two miles off. Upon going there, the officer was not at home, but some of his relatives advised the father to go to Mr. Welton *without* the order. Application was therefore made to the latter gentleman about 8 o'clock in the morning, and he was requested to see the child immediately, as it was extremely ill. Mr. Welton said he would attend, but neglected to do so. " The

child continuing rapidly to get worse, the anxious mother, about three o'clock in the afternoon, hastened to the father, who was threshing in a barn about half a mile from his house; who then obtained a horse, and went again for Mr. Welton, and between five and six o'clock in the evening he visited the child. The father had again to go to Woodbridge, the same evening, for the necessary medicine; thus making the poor man travel, at a moderate calculation, 22 miles for the doctor and medicine. Mr. Welton directed the parents to let him know early the next morning (Wednesday) how the child was. The father accordingly got to his residence by eight o'clock, but was detained there till ten, without seeing Mr. Welton, who told him, *if* the child was alive when he returned, to have it put into *a warm-bath.* Death, however, had rendered this unnecessary: the poor child had died soon after the father left home!"

And this is the system of parish *relief* which at present prevails in England, under what is called an *amended* poor-law! There was no inquest neither, it appears; though most undoubtedly there ought to have been one—when a jury of honest Englishmen might have an opportunity of expressing their opinion on the gross grievance, the criminality, attaching to the originators of such measures. But these are points which perhaps rather belong to the province of the general press; our field is limited to considerations more strictly of a professional nature, and our object now is to inquire how this odious system may be altered in any way for the better; preserving, of course, for all medical men concerned, their respectability at least, together with a more equitable chance of adequate remuneration. Viewing the subject in this light, we confess we cannot suggest any thing preferable to the mode pointed out by Ruricola, for ameliorating the condition of parish medical officers. We have every confidence in the thorough information which our correspondent possesses, and we look upon his suggestions as founded on actual experience—the best earnest of their practicability.

In the letter which we publish to-day there are several valuable hints, which we hope will attract the attention and support of the profession generally.

The scheme for a fair remuneration of parish surgeons, for example, seems one that by all means ought, if possible, to be carried into effect. What can be more equitable than that the payment of the medical attendant should be arranged according to a fixed scale—the amount depending on the population of the parish, its density, and the proportion of the pauper to the other inhabitants? The position also of the surgeon within the sphere of his duties, or his residence *at a distance*, should be taken into account; as well as a liberal allowance made for his outlay in providing proper medicines, and his time and trouble in their application.

The case above narrated by Mr. Denham exemplifies, in a marked manner, the mischief—oftentimes fatal—which may arise from the present mode of procuring and granting *orders.* The niggardliness, combined with the obstinate ignorance of a *relieving* officer, may be productive of irreparable injury.

We see, in the remedy proposed by Ruricola, nothing but what is reasonable and proper. "The person to whom all applications for medical relief should in the first place be made, is *the medical officer himself*, and he should be authorized, in cases of emergency, to give immediate assistance; but as he cannot be expected to judge of the pecuniary circumstances of the patients, they should be required, within a specified time after their application to

the surgeon, to send to the relieving officer for an *order*: nor should this functionary be required to give it, unless the circumstances of the applicants entitled them to parochial relief, and unless they produced a certificate from the medical officer, stating that their cases needed attendance."

By following so simple a plan as this—which, after all, is only that which is commonly practised at most hospitals and dispensaries—precious time, in the incipient stages of disease, would be saved—humanity would be consulted, in sparing the bandying-about which too frequently falls to the lot of the unfortunate patient before he can have a chance of being relieved—and we question if it would not ultimately prove to be the cheapest plan, if the Poor Law authorities would but take the trouble to bethink themselves, and give it a fair trial.

In all that our correspondent says respecting the summary and uncivil manner in which medical opinions are at present sought by the Boards of Guardians—namely, by *summoning* the medical officers to give their special attendance, sometimes on the shortest notice—we cordially concur. It has long appeared to us a degrading and unworthy mode of proceeding, and one which should be protested against in every case — if not wholly scouted. Why not make the medical officers *honorary members* of the Boards, and thus treat them as men of liberal education—or even as respectable members of society? The only possible objection to this might be that questions are sometimes entertained by those Boards respecting the *conduct* of the medical officers. But, as Ruricola says, in such cases—if common delicacy would not prompt them (the medical men) to withdraw, it would be easy to provide a rule for their temporary exclusion on such occasions.

We scarcely dare hope, however, that a reform of the system to this extent will ever be effected, as long as the body of the profession acts without concert; as long as a number of its members are found acting upon a selfish principle; and above all, as long as the Boards can find individuals not only acceding to the principle of "tender," but degrading themselves to the rank of menials and humble retainers. To persons of other callings and professions, who are not immediately conversant with parish proceedings, it must seem incredible that medical men should be subject to such petty humiliations; they cannot believe that men liberally educated would stoop to such unworthy treatment, or accept the wretched pittance offered to them—almost as if they were themselves paupers. Surely the length of time spent in this miserable bondage must have wrought a sad change in the body professional, when the iron entering into the soul is not felt, or, if felt, is endured without a murmur.

EXPOSURE OF MATERIALISM.

In our last number we left Mr. Roberton to speak for himself; and those who read his first able letter, will not need prompting to move them to a perusal of the second. But such readers as may not yet have opened that part of the journal (if there be any such) will find a rich treat in store for them in the admirable pieces of criticism to which we allude.

PARIS SCHOOL OF MEDICINE.

The celebrated M. Broussais delivered the introductory oration on the recent opening of the Faculty of Medicine in Paris, and appears to have been received with no small degree of enthusiasm by his audience. After an eulogy on Dupuytren, and some details regarding

the establishment of the new Museum of Anatomy which now bears the name of the illustrious deceased, he proceeded to give a sketch of the different medical theories which at present prevail. The gist of his discourse was to advocate free discussion, and may be comprised in one of his phrases—"*la polemique est l'âme de la science.*"

LECTURES

ON

SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

Direct Symptoms of Diseases affecting the structure of internal Organs, known chiefly by means of Auscultation—Modes of Auscultation—Preliminary Acquaintance with Morbid Processes essential to its successful Use—General estimate of its Value—General Directions for its Use—Auscultatory signs of Healthy Lungs—Auscultatory signs of Diseased Lungs; known in the acts of breathing, speaking, and coughing. These sounds consist in dry *sounds and* moist *sounds—Rhonchus, Sibilus, Crepitations.*

RECOLLECT for a moment the inquiry in which we were engaged, and how far it has proceeded. It is an inquiry into the nature of symptoms; and hitherto we have spoken of symptoms *directly* referable to the part affected; those which regard its sensations, and those which regard its functions; and we have endeavoured to estimate the information which these are respectively calculated to convey. We have spoken also of those which directly regard its structure; and are now considering the information to be gathered from them.

This information, it should seem, is necessarily very limited in regard to internal organs in general; but the thoracic organs are excepted from the rest, because, being within the cognizance of another sense, and thus subjected to a method of investigation peculiarly applicable to themselves, all their actions and conditions are more clearly perceived and known. This is the method of auscultation.

There are different modes of performing auscultation. In one mode we apply the ear itself to the surface of the chest: this is (what is called) immediate auscultation. In another, we apply the tube to the chest, and the ear to the tube: this is mediate auscultation. In another, without applying the ear to the chest either immediately or mediately, we strike its walls with our fingers, and listen to the sounds which result: this might be properly called auscultation by percussion. But percussion and auscultation are often spoken of, as if they were different things, whereas they are only different modes of appealing to the same sense; for we gather our information equally from what we hear, whether we strike the chest, or apply our ear to it, or use the instrument.

I have often taken occasion to point out to you the importance of pathological knowledge to the just diagnosis and the successful treatment of disease; and, as a part of pathology, I have laid especial stress upon the knowledge of morbid processes. The use which you will or will not be able to make of auscultation, will depend upon your knowledge of the pathology of those organs to which it is applied.

The sounds which reach the ear through the walls of the chest during breathing, or speaking, or coughing, varied and modified by divers diseases of the organs within, are easily discriminated. Any person not deaf will soon learn that there is some distinction of these sounds. But we may distinguish them correctly, and call them by right names, and make a musical scale of them, if we please, and still know nothing of the morbid conditions which they indicate, and out of which they arise. These cannot be discovered by a discriminating ear *only;* they must first be known what they are in themselves. By means of auscultation, various diseases of the heart and lungs are capable of being detected with wonderful certainty; but the power of so detecting them belongs to those only who have studied these diseases in all the processes of their formation, and progress, and results.

It is with hearing as it is with the other senses. When they are taxed to give intimations to the mind concerning the objects by which they are impressed, it is necessary that the mind should have a previous knowledge what those objects are. Place a man within sight of London, and give him a telescope, and tell him to look for St. Paul's. St. Paul's he will undoubtedly see, and many a striking object besides; but he will not be able to distinguish it from Westminster Abbey or the Monument, unless he is previously instructed what sort of building St. Paul's is.

A child will at once perceive a difference between the fragrance of the vio-

let and of the rose; but it must know the violet, and know the rose, and smell them both singly, and by turns, before it can assign to each its peculiar sweetness.

Any man can discern a difference between the sound of a trumpet and of a drum; but he must have been where trumpets have been blown, and drums been beat, ere he can tell which sound belongs to each. My voice is different from yours; but a man must be familiar with you and with me, and have heard us speak a hundred times, before he can distinguish us by our voices.

So diseases of the chest have, as it were, different voices; but we must first be familiar with the diseases themselves, and then be accustomed to hear them speak, ere we can tell one disease from another by its voice.

What *are* diseases of the chest? Pneumonia, pleurisy, phthisis. And *do* we mean that auscultation can distinguish each of these from the other? Yes, truly; and we mean more than this—much more.

Pneumonia, pleurisy, and phthisis, are only the complex of several morbid processes and results. There is no such thing as a pneumonic, a pleuritic, or a phthisical sound. Pneumonia, pleurisy, and phthisis, have no sounds that are peculiar to themselves *as such*: but the sounds that we hear in these diseases result from certain morbid processes going on, and certain changes wrought upon the structure of parts; which processes and changes make up the complex to which we give a name. We hear the sounds denoting that this part of the lung is loaded with fluid, that part condensed with solid matter, and another hollowed with cavities. Thus we get at inflammation; thus we get at phthisis. We anatomise by auscultation (if I may say so), while the patient is yet alive, the very processes and changes of structure of which inflammation and phthisis consist: and so of other diseases.

Auscultation professes to make us acquainted with the actual condition of the lungs in many of the most important diseases incident to them—their actual condition at any *particular time*, and their changes from one condition to another *from time to time*.

I am not aware that, before auscultation lent its aid to diagnosis, we could do more than speak generally concerning the diseases of the lungs during the life of the patient. We could affirm generally that the lungs were inflamed; and, knowing, from our acquaintance with morbid processes, that it was the tendency of inflammation to produce such and such changes of their structure, we were aware what perils it involved, and could anticipate with tolerable accuracy what we should meet with when the patient died. So, too, we could affirm generally that there were tubercles or vomicæ in the lungs, and, understanding the forms and processes of phthisical disease, we could foretell in the main what we should find after death.

But auscultation anticipates the disclosures of morbid anatomy. Nearly all that dissection can unfold, it tells while the patient is yet alive. It does more: it brings us acquainted with diseases long before they have reached their fatal stage. By dissection we come in with our knowledge *at last*, and gain assurance of the disease from its ultimate results. By auscultation we are often—very often—enabled to make our knowledge keep pace with the disease from its least and earliest beginnings, through all the stages of its progress to the last. By auscultation we contemplate a living action going on, and have cognizance of it while it is yet at work. By dissection we contemplate the ruin as it is left, when all action has ceased.

I am not going to give you a regular didactic discourse upon auscultation: you can only learn it for yourselves, by the use of your own ears, in the wards of the hospital. And even by your own ears it is hardly possible to learn it any where except in the wards of a hospital; for you must have many patients to practise upon at the same time; and, moreover, you must have many fellow-students engaged at the same time in making the same observations with yourselves, that you may compare notes together, and agree about what you hear. I am quite sure that no man can arrive at any useful or safe conclusions from auscultation, if he studies it alone. I speak from experience when I say this. When I first turned my attention to auscultation, I found so many sources of deception connected with it, that I determined to admit no fact which was not attested by others besides myself; and I would advise you to proceed at first with the same scrupulous care. "That every thing is easy when you know it," sounds like the simplest of truisms; but, indeed, it is a very wise apothegm. It imports that, be a thing ever so difficult, you may, by taking the necessary pains, obtain such a mastery over it, as to be surprised that you ever thought it difficult at all. Auscultation surely is not the most difficult thing in the world; neither is it the easiest. It is beset with many perplexities, and requires much time, and labour, and patience, and caution, to master it perfectly: but, being mastered, it becomes the safest, simplest guide, within its proper sphere, to a just diagnosis.

But auscultation, I have said, can only be learnt within the walls of a hospital. Yet, perhaps, I may be able to give you some general directions how to proceed, which may be of use to you; and I wish to speak of auscultation at present as it respects the lungs only.

Now before you seek to acquaint yourselves with the sounds which indicate diseases of the lungs, you must learn those which are expressive of their healthy state; for the healthy sounds must be your standard of comparison in judging of the unhealthy.

It is useless for me to attempt to describe (what is called) "the healthy respiratory murmur:" I could only tell you that this sound is like some other sound with which you might be more familiar. But in a few weeks you will know the respiratory murmur so well by experience, that it will itself become the most familiar of all sounds. The pure perceptions of sense cannot be made clearer by descriptions and similitudes.

I would recommend students to practise auscultation upon each other, for the sake of learning what the healthy respiratory murmur is; and to do it often, and upon many individuals. The respiratory murmur is, I believe, the same in kind in all men who have healthy lungs; but it has differences of degree belonging to it in different men, which are somewhat puzzling at first. The respiratory murmur does not reach the ear with the same clearness and loudness in the fat and the lean man. Fat and muscle damp the sound, where they abound above measure, as effectually as coats and waistcoats. Ausculting a man who is very fat and muscular, is like ausculting a man with his clothes on: you must make the same allowance in both cases.

But still the reason why the healthy respiration is more or less audible cannot always be found in the integuments of the chest. It often happens, that in a thin spare man, whose lungs are perfectly sound, you can scarcely hear it at all, while in a fat man you hear it most distinctly; and what is more remarkable, in a fat woman, even through the mamma.

People seem to me to differ very much in the mode and intensity of their breathing: some fill their lungs at every inspiration: the air appears to go further, and to dwell longer, within their lungs. They breathe as if they had a luxury in breathing; and your ear seems to follow the air through every cell and vesicle as it goes in and out. Some, on the contrary, let the air just enter into their lungs, and come back again. They breathe as if they were afraid of breathing; and your ear can hardly detect any respiratory murmur except when they breathe with a forced effort.

It is probable that these diverse modes of breathing, in people perfectly healthy, are required by peculiar states of the circulation; and that they are natural and necessary provisions, not only consistent with health, but essential to it.

In children the respiratory murmur is far more audible than in adults; and on this account it would be well for those to whom auscultation is new, to make their first trials upon children, that they may know what the healthy respiratory murmur is in its full and complete developement.

That the parietes of a child's chest are thinner, there can be no doubt; and this *may* be one cause why its breathing is more audible. But the mode and intensity of the breathing itself is the chief cause; and this peculiar breathing of a child is in obedience to some natural necessity, and that necessity is probably respective to its circulation.

In adults (even in fat and muscular men and women) the respiratory murmur is sometimes as loud as in a child. But then it is only in *some part* of the lungs that it is so; and when this is the case, it is the result of disease, and the disease is demonstrably of a nature to require that a larger quantity of air should be received into that portion of the lungs whence the louder respiratory murmur issues, and that there should be a more energetic act of respiration.

All this you will soon be able to verify for yourselves, by numerous cases in the wards of the hospital.

Having learnt the natural respiratory murmur, the sound which indicates that the lungs are healthy, you have got your standard of comparison, and are now prepared to judge of the sounds which denote their disease, as far as they are connected with the respiration. But you have got more than a mere standard of comparison by which to try the quality of other sounds. You are enabled to appreciate *simple* defects and failures of the respiratory murmur itself: and, indeed, it is as important a part of the business of auscultation to learn the extent to which the respiratory murmur is absent, as to discriminate the kind and character of the *new* sounds which are present and have superseded it. Besides, the diseases of the lungs are neither few nor inconsiderable, in which auscultation finds no new or unnatural sounds whatever, but only the natural respiratory murmur abated, or abolished: and these *privative* signs are as valuable helps to the diagnosis of pulmonary disease, as any that are most positive and real.

But, after all, let it be borne in mind, that the auscultatory signs of pulmonary disease are not all developed in the act of breathing: many occur in speaking or coughing; as will hereafter be shewn.

It seems to me that it would be enough for all practical purposes, if the unnatural sounds referable to the lungs, whether in breathing, speaking, or coughing, were divided *generically* into two; into *Dry* sounds and *Moist* sounds.

By dry sounds I mean those which result when bronchi, vesicles, or pulmonary cavities, present impediments, or rebounding surfaces, to the passage of air, and thus become sonorous or vocal from reverberation. By moist sounds I mean those which result, when bronchi, vesicles, or pulmonary cavities, present fluid to the passage of air, and thus yield a crackling or bubbling noise from the mingling of air and fluid together.

Of these sounds, the dry and the moist, I will point out such well-marked varieties as (I conceive) need to be understood, and will endeavour to give to each an appropriate name; taking care in the meantime to treat the subject as little artificially as possible, while I state fairly and faithfully, from my own experience, *how* I have used, and *what benefit* I have derived from using, this newly invented key to the diagnosis of thoracic diseases.

But before I employ any terms to designate particular sounds, I would remark that the language of auscultation is not yet uniform. All writers do not use the same terms to designate the same things; and, until they do, some inconvenience must continue to be felt. Under these circumstances, I shall take the liberty of using those which have become current in St. Bartholomew's Hospital, and have had here a certain meaning attached to them.

In considering the direct symptoms of diseases of the lungs derived from auscultation, I will begin with that part of their structure which is most obnoxious to disease; for there *is* a part in which disease is found most frequently to begin, and to which, wherever else it may begin, it is almost always found ultimately to reach. This is the mucous membrane of the bronchi and their ramifications.

It is essential to the healthy respiratory murmur, not that the bronchi and their ramifications be merely free and pervious in every part, but that their surface be equal and smooth, and lubricated with moisture, and that the moisture be not in excess. If the surface be unequal, rough, or unlubricated, dry sounds reach the ear in the act of respiration; if there be excess of moisture, the sounds that reach the ear are those of air mingling with fluid. The dry sounds thus proceeding from the air-passages I will call *Rhonchus* and *Sibilus*, and the moist sounds *Crepitations*.

This Rhonchus and Sibilus, and these crepitations, are always produced in breathing, not in talking or coughing. And first I wish to speak of what they are in themselves, and of how they interfere with the healthy respiratory murmur; and then I will endeavour to estimate their pathological import.

The terms Rhonchus and Sibilus are perhaps as intelligible in themselves as they can be made by further description. Rhonchus is the larger and hoarser sound; Sibilus the smaller and shriller. And, from what you must familiarly know of the sounds produced by blowing into a pipe of larger or smaller size, you will readily conceive that Rhonchus proceeds from the bronchi in their first divisions, and Sibilus from them in their minute ramifications, or the vesicular structure of the lungs.

Rhonchus often occurs alone. It is often the only unnatural sound that is heard; and then the affection is of the bronchi in their first or larger divisions exclusively. In this case, to whatever degree the rhonchus supersedes the healthy respiratory murmur, it does so not in the sense of preventing it *from taking place*, but in the sense of preventing it *from being heard*. The Rhonchus overpowers the respiratory murmur. The greater sound overpowers the less; but the less is extant notwithstanding.

The reason is, that the bronchi in their first divisions have nothing to do with producing the respiratory murmur; it does not arise in *them*, but in the lesser ramifications and vesicular structure beyond them; therefore they have no power to hinder the respiratory murmur, except when they suffer such impediments as absolutely preclude the access of air even to themselves, and consequently must prevent its further progress.

But in point of fact it seldom happens that the Rhonchus is loud enough to overcome the murmur altogether; and while they exist concurrently, the ear has often a distinct perception of both. There is a loud hoarse sound in several parts, and there is also, perhaps even in the same situations, a clear respiratory murmur. The murmur is, as it were, heard through the rhonchus. In such cases some of the *larger* bronchi contain the cause productive of the dry sound, but offer, nevertheless, hardly any impediment to the free passage of air, which, reaching the lesser bronchi and vesicles of the lungs, and finding them healthy, glides through them, and produces as it goes the murmur which is the best evidence of health.

So, too, Sibilus often occurs alone; it is often the only unnatural sound that is heard during respiration; and then the

affection is of the bronchi in their lesser ramifications, or in the vesicles of the lungs. But in this case, to whatever degree the Sibilus supersedes the healthy respiratory murmur, it does so not in the sense of preventing it from being heard, but of preventing it from taking place. And the reason is, that *the parts* which produce the Sibilus and the respiratory murmur are the same; but the *conditions* under which they produce them are different. Consequently the sounds themselves are incompatible with each other, and cannot co-exist.

But Rhonchus and Sibilus, though each often occurs alone, do just as often occur both together. And nothing more is wanted to this event than that a bronchus through its several divisions and ramifications, large and small simultaneously, should contain the cause capable of modifying the vibrations of the air in its passage.

The moist sounds occasioned by the mingling air and fluid in the bronchi and their ramifications during the act of breathing, which have been variously denominated, I call by one name, Crepitations; and of Crepitations I only make the distinction of *Large* and *Small*.

Sounds so produced are ever without variety, and can only differ in being greater or less. And according to their largeness or smallness, and the space to which they are extended or confined, they become important signs in all those diseases where a separation of fluid from the mucous membrane of the air-passages is a pathological ingredient.

The *Large* Crepitation is occasioned by the mingling of air with fluid in the bronchi, at their first divisions. It arises from the same parts as the Rhonchus, but results from a different condition.

The *Small* Crepitation is occasioned by the mingling of air with fluid in the bronchi at their lesser ramifications, or in the vesicles of the lungs. It arises from the same parts as the Sibilus, but is owing to a different state of those parts.

The Large and Small Crepitation have the same effect of suppressing or superseding the respiratory murmur that the Rhonchus and Sibilus have; and each after its own manner respectively. The Large Crepitation, proceeding from the same parts as the Rhonchus, may overpower the murmur, but cannot prevent it from taking place; whereas the Small Crepitation, proceeding from the same parts as the Sibilus, is instead of the murmur, which it abolishes altogether.

All the bronchi in their primary divisions may contain an excess of fluid, and *Large* Crepitation may be heard over every part of the chest; and yet, through that *Large* Crepitation, a practised ear will be able to detect the respiratory murmur; obscured, indeed, by the louder sound, but itself genuine and healthy.

So, too, all the bronchi in their lesser ramifications, and the whole vesicular structure of the lungs, may contain an excess of fluid, and *Small* Crepitation may be heard in every part of the chest; but, in the meantime, no ear is subtle enough to catch the natural respiratory murmur, for no such murmur exists.

The Large and Small Crepitations may co-exist together in every variety of combination. You may have both Large and Small in every part of both lungs; or Large in one lung, and Small in the other; or Large and Small in different parts of the same lung. And with Large and Small Crepitation thus differently combined, Rhonchus and Sibilus may be still intermingled, and some natural respiratory murmur be here and there distinguishable among all the rest.

I wish now to consider the pathological import of the several auscultatory signs which have been specified, before I proceed to others; for they are practically the most momentous of all. They are few, but they convey vast information, according to the manner and combinations in which they occur. Do not be surprised at this. There are but twenty-six letters in the alphabet; yet these compose all language; and language conveys all knowledge. Think of knowledge, its vastness, its variety, its multitudinous particulars! Yet language has compassed it all; language has delineated it all; and language is daily furnishing to you and to me little pictures of such portions of it as we desire to survey. Still the wonders of language are comprised in twenty-six letters.

Let it not, therefore, seem strange that many conditions of disease are signified by a few simple sounds.

ST. GEORGE'S HOSPITAL.

CASES; WITH CLINICAL REMARKS.

Acute Rheumatism, treated with large doses of Calomel and Opium—Case cut short at once by Bleeding—Severe Painter's Colic, cured in forty-eight hours — Chorea cured by Arsenic, after Iron had failed.

NUMEROUS cases of rheumatism, in its different forms, are at all seasons to be found in the wards of this hospital, and we shall from time to time illustrate the treatment adopted by the different physicians, which we observe varies a good deal, even in cases apparently analogous. We last week gave two cases of the *arti-*

cular form of the disease, in which colchicum is so efficient, at least in the early stage of the disease; this week we give two cases of the *diffuse* rheumatism, which yielded very speedily to calomel and opium; and one which appears to have been *extinguished* by a single large bleeding.

On another occasion we shall give some cases of the disease in its chronic form, whether affecting the common fibrous or bursal textures.

Henry Gibson, ætat. 21, a groom, admitted October 28th, under the care of Dr. Macleod. Has acute pain, with considerable swelling and redness, of both hands, particularly in the spaces between the wrists and knuckles, which are very tense and exquisitely tender; pulse 90, bounding; tongue white. Was exposed to cold ten days ago, soon after which he was attacked with pain and swelling of the feet, the pain extending to the knees and hips. Two days ago the lower extremities began to get better, and his hands to become painful.

Mittr. Sanguis, ad ℥xii.
℞ Calomel, gr. x.; Opii, gr. ii. M. fiant pilulæ duæ hora somni sumendæ.
Haust. Sennæ, cras primo mane. Fever diet.

October 29th.—Pain somewhat relieved; blood buffy, and much cupped; pulse 76, less active; bowels confined, the senna draught having been inadvertently omitted.

Habt. Haust. Sennæ quamprimum. Repr. Pilulæ, h. s. et Haust. cras mane.

30th.—Bowels were freely purged yesterday afternoon, and have also acted several times this morning. Pains very much relieved; swelling and redness nearly gone; pulse 70, softer.

Repr. Medicamenta.

November 1st.—Gums becoming affected; bowels freely purged; pains gone.

Pulv. Ipecac. Comp. gr. x. om. nocte. Omit. alia.

10th.—No recurrence of rheumatism. Discharged cured.

Thomas Jacobs, ætat. 57, labourer, admitted October 28, under the care of Dr. Macleod. Was attacked, five weeks ago, with pain in the limbs, after exposure to cold. About three days ago the pain in the right hand underwent a severe exacerbation, the part becoming red and swollen all over. Pulse frequent, and bounding; skin hot; tongue white.

Mittr. Sanguis. ad ℥xiv.; Calomel, gr. x. Opii, gr. ii. hora somni; Haust. Sennæ, cras mane. Fever diet.

October 29th.—Pain mitigated, but still severe; blood very much cupped, with a thick and a cloudy mass like coagulated albumen floating in the serum; bowels have acted only once.

Habt. Haust Sennæ quamprimum. Repr. alia ut antea.

31st.—Gums becoming tender; bowels freely purged; pains much better; redness and swelling disappearing.

Pulv. Ipecac. Comp. gr. x. om. nocte. Haust. Sennæ, alterno quoque mane. Fish diet.

November 10th.—Nothing worthy of remark has occurred since last report, the convalescence having gone on progressively. Discharged cured.

Dr. Macleod remarked, in reference to rheumatism, that there was perhaps no disease with respect to which opinions and statements appeared to be more contradictory; but that much of this discrepancy depended on the want of a due attention to the form and stage of the disease. According to his experience in the acute *diffuse* form of rheumatism,—that in which the swelling is not most developed at the small joints, but involves all the contiguous fibrous parts,—no treatment is so effectual at the commencement as the abstraction of a moderate quantity of blood, with full doses of calomel and opium at night, followed up by free purging next day. In a first attack of very recent date, a full bleeding sometimes at once arrests the disease; this, indeed, is not generally the case, but a striking example of it occurred at an early period of the present year, in a patient under his care. He had also seen acute rheumatism at its onset arrested by calomel and opium without bleeding or purging; but for this purpose it must be very freely administered, and is apt to produce troublesome salivation. He had not tried the effect of purging without the calomel and opium; but he was satisfied that the relief was much greater when the bowels were freely acted upon, than when this was not attended to. The general effects of the plan were well illustrated by the cases given above, both of which were admitted, and both discharged on the same day.

We subjoin from the case-book, the example in which an attack of acute rheumatism was *extinguished* by one large bleeding. It is right to remark, however, that another case, in a less favourable subject, admitted the same day, and similarly treated, did not recover till the calomel and opium were administered.

John Hudson, æt. 35, a hair-dresser, of

robust habit, admitted January 21, 1835, under the care of Dr. Macleod. The left foot and ankle, as well as the hand and wrist of the same side, are much swollen, tense, and red. The parts are exquisitely painful, especially on the slightest movement. Pulse 105, full and hard; skin hot; tongue loaded; bowels open, from medicine taken this morning; urine scanty, and high-coloured.

Eight weeks ago had erysipelas of the face, followed by some pain in the chest, and cough, the latter of which still continues. Has had rheumatic pains flying about him for a week, which, the day before yesterday, became fixed in the parts above mentioned, and which soon began to swell, the pain becoming progressively more and more acute. Has not had rheumatism before.

Mit. Sanguis, ad ℥xxx. App. Lotio spirituosa partibus inflammatis. Fever diet.

22d.—Experienced great relief within an hour after he was bled, since which time the swelling of the hand and foot has progressively, but rapidly, diminished, and is now entirely gone; the skin being shrivelled, from the rapidity with which the tumefaction has disappeared. Has no pain whatever except when he moves. Blood buffy, and very much cupped; pulse 80, soft; bowels not open. The spirit lotion has been applied only to the hand, and its use was not commenced till the evening, when the pain and swelling were already rapidly diminishing.

Haust. Sennæ, quamprimum et repetatur cras mane si opus sit.

From this time he suffered no inconvenience except from his cough, which was relieved by oxymel of squills; and he was discharged cured on the 3d of February.

Another disease of a different kind, in which calomel and opium proved very efficient, was illustrated by a case which happened to be in the hospital at the same time as the two cases of rheumatism first given — namely, painter's colic. As the case was a good one, we subjoin it.

Thomas Bramage, a painter, ætat. 25, admitted October 28, under the care of Dr. Macleod. Complains of violent pain in the belly, extending from the umbilicus to the loins, and shooting down to the testicles. The pain, though never entirely absent, undergoes violent exacerbations, during which the patient rolls in agony, and presses his fists upon the abdomen with all his strength. Occasional fits of vomiting. Bowels habitually costive, and have not acted at all for two days. Tongue moist, with a thin slimy coating; pulse 64, soft; skin cool.

℞ Calomel, gr. x., Opii, gr. ij., fiant pilulæ duæ quamprimum sumendæ, et hora somni repetendæ.

Hab. Ol. Ricini, ℥j. cras mane, et sumat ℥ss. tertiâ quâque horâ donec responderit alvus.

Descendat quamprimum in Balneum calidum.

27th.—Still complains of pain in the belly, though not nearly to the same extent as yesterday. Bowels have acted twice freely; gums swollen; strong mercurial fœtor in the breath.

Omit. Calomel. Rep. Opium et Ol. Ricini ut antea.

Rep. Balneum vespere.

29th.—Free from all pain since yesterday. Bowels open; pulse 80; tongue cleaning.

Sumat Opii, gr. j. om. nocte. Ol. Ricini, ℥ss. om. mane.

Nov. 2d.—Discharged cured.

Another case which excited some interest from its severity and obstinacy, was one of chorea, which strikingly illustrated the fact, that arsenic will sometimes succeed in curing that disease when the carbonate of iron, in pretty full doses, has failed.

Mary Anne Gilling, ætat. 9, admitted September 2, labouring under chorea in a severe form. The convulsive movements nearly constant, affecting both the upper and lower extremities, and preventing her from being able to walk. She is pale, and looks out of breath; appetite bad; bowels torpid. Nearly a fortnight was spent in regulating the bowels, by means of calomel, castor oil, and aloes, variously administered. At the end of this time the action of the bowels was re-established, and her health was better, but the convulsions were in no degree mitigated. She had also—

Tinct. Ferri Ammoniat. ℨj. ter die, ex Aquæ pauxillo.

and the shower-bath was used every morning.

16th.—The symptoms of chorea remaining as above, she was ordered—

Ferri Carbon. gr. x. ter die. Haust. Sennæ al. quoque mane.

18th.—No change.

Ferri Carb. gr. xx. ter die. Rep. Haust. et Balneum.

22d.—No change.

Ferri Carb. ℨj. ter die.

28th.— Some temporary improvement appeared to have taken place for a day or two, but the chorea is now as bad as ever.

Ferri Carbon. ℨiss. ter die. Rep. alia.

Oct. 1st.—No change.

Ferri Carb. ℥ij. ter die. Rep. alia.

5th.—No change. The iron was now discontinued, and she was ordered—

Liq. Arsenicalis, ♏iij.; Spirit. Lavendulæ, ℥j. Aquæ, ℥vij. M. fiat Haustus ter die sumendus.

By the 9th the dose had been increased to ♏vj. ter die, when she was observed to be decidedly steadier. By the

14th the dose amounted to ♏viij., when her improvement became so marked, that it was not deemed necessary to increase the dose any farther. By the

19th she could sit up, having previously remained constantly in bed, from being unable to prevent herself from falling. By the

26th she was perfectly steady, and could walk about without any difficulty. Her general appearance had also improved prodigiously. In a few days afterwards she was discharged cured.

Dr. Macleod remarked on the 5th, when the iron was discontinued, that he had seen several instances in which chorea, which had resisted the use of iron, speedily yielded to arsenic. He did not mean to say that iron, particularly the carbonate, might not possibly succeed if persevered in for a certain length of time; but as he had never seen any ill consequence result from the liq. arsenicalis properly administered, and as it cut short a troublesome disease, which lingered for an indefinite period under other remedies, he did not think we were warranted in neglecting to administer it. Purging he only regarded as an auxiliary—one which was very seldom sufficient to cure the disease by itself. The shower bath ought always to be used, unless there be some strong reason to the contrary.

SUGGESTIONS TOWARDS A BETTER SYSTEM OF

PAROCHIAL MEDICAL ATTENDANCE.

By Ruricola.

To the Editor of the Medical Gazette.

Sir,

It has struck me that some misapprehension might arise from an apparent discrepancy in my last communication. The remuneration for parish surgeons is there proposed, in one place, to be *fixed*; in another, to *vary*. I would explain it thus:—Let there be a *fixed scale* of remuneration, adapted to the following *varying* circumstances—viz. to *the number of sick paupers*, which will, of course, depend partly on the "population of the parish," and partly on its proportion of pauper inhabitants; and also to the *labour of the medical attendant*, which will depend not only on the above circumstances, but on the "*density* of the population," and the "*distance* of the parish from his residence."

The next proposition I have to suggest with regard to pauper medical relief, is the adoption of a different method of giving *orders*. It is evident that so long as this depends on the caprice or convenience of a relieving officer, the poor must suffer a needless hardship.

Accident and sudden illness require, of course, much more immediate attention than applications for weekly pay or provisions: the circumstances are totally dissimilar. The officer who may be qualified and prepared to bestow sufficiently prompt attention on *one* set of applications, may be, on various accounts, quite unable, as well as unsuitable, to act as the necessities of the case may require in the *other*.

The person, therefore, to whom all applications for medical relief should, in the first place, be made, is the *medical officer himself*; and he should be authorized, in emergency, to give immediate assistance; but as he cannot be expected to judge of the pecuniary circumstances of the patients, they should be required within a specified time (say one or two days) after their application to the surgeon, to send to the relieving officer for an "order;" nor should this functionary be required to give it, unless the circumstances of the applicants entitled them to parochial relief, and unless they produced a certificate from the medical officer, stating that their cases needed attendance.

This arrangement will place the medical relief afforded to paupers nearly on the same footing as that supplied by hospitals and dispensaries; for in these institutions, also, the medical officers are the *first* judges, the boards of governors, or committees, the *second*, of the fitness of the applicants for assistance.

Of course, if the relieving officer refused an "order," the Board of Guardians would be the court of appeal; and if *here* the refusal was confirmed, the medical officer must consider the case as treated on his own account; and though he might occasionally *lose* in this way, it would doubtless be far better for him than the injury he now sustains, by the frequent withholding *slight cases* and *first stages* of disease, and so entailing on him subsequent long and expensive attendances; while for the

poor this plan would be incalculably more humane, as they would in all cases insure an early attention to their wants, by having to apply *at once*, and without any intermediate step, to the only person from whom, sooner or later, relief can be obtained.

Thirdly, The evils that have arisen from the present mode of appointing medical officers, naturally lead to the conclusion that the parties with whom the right of appointment at present resides are not the most fit to exercise it; and granting that, by the adoption of a fixed scale of remuneration, many of the inducements to appoint *too few*, or *unsuitable* medical men, would be removed, still there appears to be no good reason why the Boards of Guardians should continue to supersede the whole body of rate payers, in a matter where the latter must be allowed to have the best opportunity of judging rightly.

Indeed, if the power of reducing the salaries of the medical officers (by the tender system or otherwise) were taken away from the Boards of Guardians, they would probably be quite indifferent about retaining *the right of appointment*, which would alone remain.

The rate-payers of each parish, on the other hand, have the strongest inducements to select that surgeon who, from the confidence bestowed on him by the inhabitants, and from his previous long residence in or near their parish, might justly be esteemed the fittest person to take charge of their sick poor. The lower order of rate-payers would be particularly tenacious of exercising the right of election, feeling an additional interest in the proper treatment of those, among whom might be found their own relatives or connexions.

Tried professional character would then have its due weight; previous neglect of duties would meet with its sure punishment; and *fitness* for the office would be the sole consideration of the electors. The mode of conducting this election might be the same as that employed for electing the Guardians of the Parishes, which is the simplest and best that could be devised.

This desirable restoration of the privileges of the rate-payers, in connexion with the separate calculation of the medical salaries for each parish, would effectually destroy the present odious system of *medical districts*, so irrational in itself, so offensive to the profession, and so injurious to the poor.

As, however, the executive administration of parish affairs rests with the Boards of Guardians, it would be right that they should possess the power of suspending the medical officers, or of withholding their pay, for well-ascertained omission of duty.

Fourthly, There is still a question as to the proper manner of obtaining *medical opinions* at the Boards of Guardians. At present this is accomplished by *summoning* the medical officers. It must be confessed that this is rather an unceremonious proceeding towards members of a learned profession; and it may be fairly asked, what evil could result from making the medical officers members of the Boards of Guardians, *ex officio?* Since the remuneration given must, in the present state of the country, be far below the services rendered, there is no reason why the medical men should not be treated as benefactors to the poor, and, *in some measure,* as the honorary officers of parishes; and it would be but decorous to give them the opportunity of stating their opinions as members of the Boards, instead of sending a summons for them, as for any inferior functionary.

The idea of medical men being "servants" of the Boards of Guardians, must be relinquished, before the *respectable part* of the profession will have any thing to do with parish appointments.

It will not be denied that medical opinions are often of great consequence in the deliberations of the Boards. The state of the health of the paupers generally,—the approach or prevalence of epidemics,—the quality of nutriment or provisions,—the purity of water-springs,—the salubrity of the air in different parts of the union,—the supply of additional support to sick paupers,—the detection of imposture,—are all questions upon which the medical officer would be the best qualified to offer an opinion; and as to general information and intimate knowledge of the habits of the poor, these gentlemen may be presumed to be superior to most of the individuals at present composing the Boards.

There can only be one objection to the medical officers taking their seats at the Boards, and that is, the occasional necessity which might happen for investigating their official conduct. At these times, if common delicacy did not prompt them voluntarily to withdraw, a provision might easily be made for their temporary exclusion.

Besides, it is highly improbable that a medical man in full practice would have time and opportunity to attend oftener at the Board than when points were to be mooted which required his consideration.

These, sir, are the main alterations in the present system which I think it right to suggest, and shall be highly gratified if my feeble attempts in the cause elicit the opinions of any of your readers on the subject.

If a determined effort be not made to procure some amendment, the public

health and the interests of science will alike suffer by the introduction of an inferior race of practitioners throughout the country, who, if successful in maintaining their posts, will uproot the existing medical men; and, if failing in their projects, will leave the Poor Law administrators at the mercy of the established practitioners, and so possibly be the means of increasing the rate of remuneration to an amount which at present no moderate man would think of proposing.

But however the matter may be settled, there are resources for the poor, and for the established practitioners, to which one turns with pleasure, after considering the previous unwelcome subject; — these are Self-supporting Dispensaries, and other associations for mutual assurance, against the expenses of sickness among the poor.

To the benevolent individual who originated these institutions, and to those who, following his example, have in other parts of the country improved upon and carried out his principles, the community, the poor, and the profession, owe much gratitude.—I remain, sir,

Your obedient servant,

RURICOLA.

LIGATURE OF THE INTERNAL ILIAC ARTERY.

M. BARONI, one of the Professors at Bologna, has just published the particulars of a case in which he tied the internal iliac artery. The following is a brief summary of the facts, taken from the *Gazette des Hôpitaux*:—

A peasant, 22 years of age, fell from a tree, and received a deep wound in the thigh from a sickle which he carried. The wound laid bare a portion of the os innominatum and sacro-sciatic ligaments. The bleeding, however, was speedily arrested, and the wound healed by the first intention; but the patient soon after became irregular in his diet, when fever came on, followed by a collection of pus in the site of the wound; this was evacuated by a surgeon. On the 14th day a severe hæmorrhage came on. After removing the clots a jet of blood issued from the bottom of the wound. The finger was applied so as to arrest it, and the parts laid open with the knife; after which, by means of a needle curved at the extremity, a ligature was applied to the internal iliac, above the wounded point, but the hæmorrhage very soon returned. A second ligature was now placed below the bleeding orifice. Eight days afterwards some bleeding took place from another vessel at one side of the wound, which required to be tied. The recovery went on favourably, and at the end of a month the patient was well.

NOTICES.

"MEDICUS."—The Act is by no means retrospective; unless its respecting the rights of those in practice when it passed can be taken in that sense. From our correspondent's showing, its construction is entirely in his favour.

Notwithstanding our additional sheet, we have been obliged to postpone several papers for which we could not find space: the writers will be good enough to accept this as our apology; we hope to make them speedy amends.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE IX.

ON CASTOREUM.

GENTLEMEN,—As the second, third, and fourth orders of mammalia yield us no pharmacological agent, I proceed in this lecture to examine the fifth, which has been called *Rodentia* (from *rodo*, to gnaw), in consequence of the manner in which the animals of this order take their food. They have been also termed *Glires*, or *Hybernantia*.

You will observe that the *Rodentia* have no canine teeth (fig. 31); and hence

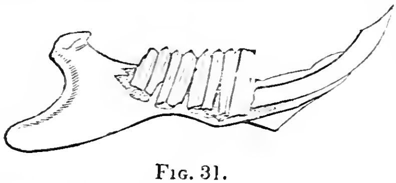

FIG. 31.

they are not adapted for seizing living prey. You see, however, that they have two long incisor teeth, which are remarkable on two accounts. In the first place they have a constant tendency to elongate, and only keep of the proper length by the friction and pressure of the antagonizing teeth of the upper jaw. In the Hunterian Museum of the Royal College of Surgeons is a beaver's skull, showing that, when the upper incisor teeth are removed, the lower ones continue to elongate. The second peculiarity is their chisel edge, which is produced by the unequal hardness of the anterior and posterior edges, in consequence of the enamel being deposited on the anterior surface only; so that the posterior edge wears down much faster than the anterior, which is thus left sharp and cutting.

Castor Fiber, or Beaver.

This animal yields a remarkable secretion, called *castoreum*, which was used in medicine by Hippocrates more than 2250 years ago. Its generic name κασтωρ. is probably derived from γαστηρ, the stomach or belly, on account of the swaggy or prominent appearance of this part. The Latins called the animal *Fiber*, because it resides at the extremities of rivers. It was also denominated the *Canis Ponticus*, or *Pontic dog* (fig. 32).

In examining the most interesting of its external appearances, I shall first direct your attention to the *fur* of the animal, which varies in its colour, so that we have brown, yellow, black, spotted, and even white beavers; but the two latter varieties are very rare. Richardson, in his *Fauna Boreali-Americana*, has never seen either of them, though he has met with black beavers, which were kept as curiosities.

The *tail* is a part peculiar to this animal, and by which it may be distinguished from the other Rodentia. It has so much of the fishy character, in consequence of being covered with greyish oval scales (fig. 32, *b*), that it is said to be allowed in some countries on fast days, when the body of the animal is prohibited. The great breadth (oftentimes five inches) does not depend on the width of the caudal vertebræ; for you observe in this skeleton (fig. 33) these bones are not more than two inches wide. The numerous strong tendons inserted la-

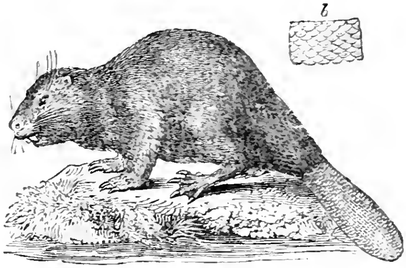

Fig. 32.

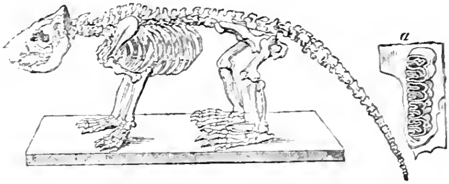

Fig. 33.

terally into them contribute to its breadth. It contains a quantity of gristly kind of fat, and is considered a great luxury by the native tribes in America, where the animal is caught.

You will observe the animal has five toes on each foot, those of the posterior extremities being webbed.

The incisor teeth of this animal are two in number; they are smooth and orange-coloured anteriorly, while posteriorly they are white. There are sixteen molar teeth, the crowns of which are flat, and the enamel being in the form of sinous ridges (fig. 33 *a.*)

I now proceed to examine the *position*, *structure*, and *functions*, of the *castor sacs*. The consideration of these subjects, however, involves a knowledge of the parts connected with them — namely, the sexual organs and the oil sacs. I must, therefore, briefly notice these.

Many persons have thought that the beaver was a *monotrematous* animal (so called from *μονος*, *one*, and *τρημα*, *opening*); that is, had a common opening for the evacuation of the urine and of the fæces, termed a *cloaca*.

But according to Brandt and Ratzeburg (and the preparations on the table bear out their statement), the beaver has no part which properly deserves to be called a cloaca. The error has arisen from the following circumstance. In the male animal the openings of the rectum, of the oil sacs, and of the prepuce, lie in a common hollow, inclosed by a large, wrinkled, somewhat hairy, cutaneous protuberance, which, according to Perrault, is easily contracted and dilated, not by a sphincter, as the anus, but simply like a slit. Carus, however, still continues to term the part a cloaca.

If you fancy the animal laid on his back, and the skin of the abdomen removed, four eminences will then be seen, placed between the pubic arch and this false cloaca. Here is a drawing from Perrault illustrating this (fig. 34.) The

two nearest the pubes are the *castor sacs*, while those next the false cloaca are the *oil sacs.* Between the two castor sacs in the male lies the *penis;* it is lodged in a long *preputial canal*, which terminates in the false cloaca, and has some analogy to a vagina; so that it is sometimes difficult to determine, until the skin be removed, whether the individual be male or female. The apex of the penis does not point towards the navel, as in the dog, but towards the tail. Here are several specimens of the bone found in the penis (fig. 35.) The surface of the penis is co-

Fig. 35.

vered with longitudinal wrinkles and pits; in each of the latter is found a dark-coloured warty-like body (fig. 36 *j*.)

The testicles, vasa deferentia, and vesiculæ seminales, present nothing remarkable. There is no scrotum. Like most other Rodentia, the beaver has *vesiculæ accessoriæ*, or blind ducts, which open into the urethra near its commencement. Just at the point where the urethra joins the penis are observed Cowper's glands.

The *castor sacs* open by a common aperture into the preputial canal. This aperture is about one inch in width (fig. 36, *f*), and is placed opposite the extremity of the *glans penis* in the relaxed condition of the organ, and about one inch from the orifice of the prepuce. Between this common orifice of the castor sacs and the glans penis is a semilunar fold (a probe, *v v*, is passed under it in fig. 37.) There is also a second, similar, but thicker, fold covering the rectum (*u u*, fig. 37.)

The *castor sacs* are pyriform and compressed. They communicate with each other at their cervical portion; but their fundi diverge outwards and towards the pubes. It was an ancient opinion that these sacs were testicles, and that when closely pursued by the hunter, the animal tore them off, leaving them behind him

as a ransom. Hence, it was said, arose the name of the animal, *à castrando*. Al-

luding to the conduct of Catullus in a storm, Juvenal says—

——— "imitatus Castora, qui se
Eunuchum ipse facit, cupiens evadere damno
Testiculorum: adeo medicatum intelligit
inguen."

This absurd notion seems to have been long ago disbelieved; for Pliny tells us that Sextius derided it, and said that it was impossible the animal could bite them off, since they were fastened to the spine. Thus is one error confuted by another; the truth being, the testicles are so placed in the inguinal region, on the external and lateral part of the *os pubis*, that they are not discernible until the skin be removed: besides, female beavers also have castor sacs. We are, however, less perfectly acquainted with the anatomy of the female than the male animals; indeed, I am acquainted with three dissections only which have been published—namely, one by Gottwaldt in 1680, one by Hegse in 1684, and one by Mortimer in 1735. Here is a drawing from the latter (fig. 38.)

Mortimer says the animal had two ovaria, and an uterus dividing into two horns (uterus bicornis), as in the bitch. The bladder lay exactly over the body of the uterus. The meatus urinarius ran upon the vagina above two inches in length. Just below the *os pubis*, on each side of the vagina, above the meatus urinarius (supposing the animal laid on her back), a pair of pyriform bags were found, about $1\frac{3}{4}$ inches long, and 1 inch broad, diverging at their fundi, or broad ends, but approximating almost closely at their necks, or narrow

extremities, which were canals communicating with the adjoining glands. The membranes which formed these bags were tough, wrinkled, and furrowed, of a livid dirty colour. They were hollow, and capable of containing about an ounce of water. Upon opening them a small quantity of a dark-brown liquor, like tar, was found, having an odour like castoreum, and in addition a smell of ammonia. It is probable the emptiness of the sacs, and the unusual quality of their contents, arose from the youth of the animal. About an inch lower, on each side of the vagina, were a pair of glands, each about $1\frac{1}{2}$ inches long, and $\frac{1}{2}$ inch broad. Their form was oblong, but irregular, and having several protuberances externally; their colour pale flesh, like the pancreas. They seemed to communicate with the castor sacs, the sac and gland on each side opening externally by one common orifice, around which were long black hairs.

The structure of these castor sacs next deserves our notice. This can in part be made out by dissection of the most recent

sacs of commerce, macerating them first in water, and then in spirit. Each sac has five coats.

1. *An external* or *cellular coat*.—Its colour is greyish. Perrault says that it is clear and transparent, and that its colour is derived from the internal coat.

2. *Muscular fibres* are inclosed in the cellular coat. They are regarded as a continuation of the panniculus carnosus, and their use seems to be the compression of the sac.

3. *Vascular coat*.—This lies within the muscular coat. It not only covers the convolutions of the fourth coat, but also sends processes in between them in a similar manner to the pia mater, which dips down between the convolutions of the brain. To this cause must be referred the *ruminated* or *nutmeg* appearance when we make a section of some of the dried sacs. This membrane is very vascular; hence the name by which I have designated it. It is said to be very thick in the Russian sacs, but I have had no opportunity of verifying this statement.

4. *Scaly* or *glandular coat*.—It has been compared by some to a mucous membrane, but its structure is in several respects different. Externally it has a shining, silvery, and iridescent appearance; internally we observe a number of small scales, which overlap each other like tiles. Their shapes are lanceolate, oblong, or semilunar, and they are smaller towards the mouth of the sac. The margins of the scales are mostly toothed, but are sometimes entire. Beneath each, and lodged in a small cavity, is a *small brown body*, varying in shape, and supposed by some to be a gland; though this opinion is doubtful. This fourth coat is thrown into numerous folds or convolutions, which are largest and most numerous in the fundus of the sac.

5. *Epithelium*.—This coat is a continuation of the epithelium of the prepuce, and lines the inside of the sac, inverting the glands and scales of the fourth coat, and therefore the castoreum must pass through it to get into the cavity of the sac.

Having now finished the structure of the castor sac, let us proceed to the examination of its contents.

The secreted substance found within these sacs is denominated *castoreum*, though this term is commonly applied to the secretion and sacs themselves, as found in commerce. The quantity of this secretion varies considerably. I suspect that sex, season, and age, are among the circumstances which affect the quantity. In its recent state this substance is thin, fluid, and of a yellow or orange colour, but becomes deeper coloured by exposure to the air. By soaking one of these sacs in hot water, you observe the secretion becomes quite soft, and similar in appearance to that in the recent state.

The *oil sacs*, which I have already noticed, are two in number—one on each side between the castor sac and anus. They appear to be of the nature of conglomerate glands, each being made up of one or of several lobes. They occur both in male and female beavers. In this preparation each sac is about two inches long, and one and a half broad. Their shape varies, but for the most part is ovate. Each sac terminates in one or more ducts which open into the false cloaca on either side of the anus. The ducts are usually so small as to allow the passage of a fine bristle only; their length is about seven lines. The external aperture of the ducts is surrounded by a small swelling. Each sac consists of—1st, an *external* or *cellular* coat; 2dly, of a layer of interlacing *muscular fibres*; 3dly, of a *firm cellular coat*, separable into two layers, between which are found little *glandular* masses; and 4thly, an *internal*, very delicate milk-white coat, easily separable, and lacerable. The glandular masses just alluded to consist of heaps (each about one line thick, and from two to eight long) of conglomerate, yellowish, flesh-red glands, from which small *ducts* proceed: these unite to form one or more larger ducts, which open into the cavity of the oil sac beneath a small fold.

The contents of the oil sacs are a fatty matter, usually of the consistence of syrup or honey, though I have sometimes found it much harder, having a peculiar odour, and a yellowish colour. It is not an article of trade, but the Indians occasionally eat it, and also mingle a little with their tobacco when they smoke. It was formerly employed in medicine under the name of *Pinguedo seu Axungia Castoris*.

There are certain muscles which compress both the castor and oil sacs. In *Brandt* and *Ratzeburg's Medizinische Zoologie* is an account of the dissection of a beaver, at Wittenburg, in 1827; and the following muscles are described as common to both castor and oil sacs (fig. 39):—

1. A thin muscle, having an arched form, passing from the penis to the posterior side of the castor muscle. It is more superficial than the erector penis (fig. 39, *h*.)

2. A muscle, arising close to the former, and expanding itself over the under surface of the oil sac (fig. 39, *i*.)

3. Another muscle, lying beneath No. 2 (supposing the animal placed on his back). It expands over the upper surface of the castor sacs, while part of the muscle crossing its fellow is distributed to the castor and oil sacs of the opposite side (fig. 39, *l l*.)

4. A small bundle arises posterior to the above, and is distributed to the castor and oil sacs of the same side (fig. 39, *n*.)

5. Fibres of the cutaneous muscle interlace with the muscles already described.

A great deal of nonsense has been written respecting the *functions of the castor and oil sacs*. One writer tells us that castoreum promotes the appetite of the animal,—another, that it improves his digestion,—a third, that it serves him for food during the winter season,—and lastly, a fourth tells us the animal besmears himself with this secretion as a protection against the action of the water. All these are gratuitous hypotheses. The most probable view of the nature of these bodies is, that the glands of the castor sacs are analogous to the odoriferous glands of man and many other animals, while the oil sacs are anal glands: so that there is nothing mysterious about them; they are parts analogous to those found in many other animals, though here in a high state of development.

But it may be asked, of what use is the secretion of the odoriferous glands? In the human subject, the *glandulæ odoriferæ*, or, as they are sometimes denominated, the *glandulæ tysonianæ*, are placed around the neck and corona of the glans penis in the male, and analogous organs are found around the glans clitoridis in the female. They secrete a strongly odorous humor, having a tendency to solidify, and which has been denominated *smegma præputii* (from σμῆγμα, *soap*). They are usually described as having for their object the preservation of the sensibility of the glans, and to allow the prepuce to move backwards and forwards with facility. I confess I am not satisfied with this kind of physiology. As this secretion is peculiar to the sexual organs, we are naturally led to suspect that it serves some sexual purposes. When we also see these secreting glands more largely developed in the lower animals, and bear in mind the powerful influence which the odour has on the sexual feelings, we can hardly refuse to admit that the so-called *smegma præputii* is a venereal excitant. Dr. James Blundell seems disposed to carry this notion to a great extent; he refers the fondness of rats for oil of rhodium, and of cats for valerian, to the resemblance which these substances have to the sexual odours. Now doubtless castoreum emits one of these odours; for, in addition to the argument drawn from its strong smell, must be mentioned the position of the glands which secrete it, which is the same as the odoriferous glands in the human subject—that is, around the glans penis in the male, and at the commencement of the vagina in the female.

The functions of the oil sacs are very little understood. I am surprised that so late and intelligent a writer as Richardson, in the North American Fauna, should have adopted the notion that the secretion of these sacs affords a dressing to the fur, because small ponds which are inhabited by beavers are tainted with its peculiar odour. Nature has certainly placed the organs secreting it in a very awkard situation, if such be its use. An argument against this opinion is, that many animals—as the hyena, the dog, and the fox—which cannot be called aquatic, have analogous glands (fig. 40).

The secretion of the oil sacs of the beaver is so remarkable both from its position and qualities, that I can hardly regard it as being merely excrementitious. By its lubricating property, it may act as a defence to the skin from the fæces; but this cannot, I think, be its sole use.

The *geographical* distribution of the beaver was formerly more southern than now. It appears that they were formerly indigenous to this country, since it is so stated by some old writers; and the discovery of fossil remains of the animal has confirmed the assertion. It seems they were principally found in Wales and Scotland. The latest period at which they are known to have existed here is 1188, A.D. In the western hemisphere they are found from 67° or 68° north latitude (as the banks of the Mackenzie River, which discharges itself into the Arctic Ocean), to about 33° south latitude. Say mentions the most southern range as being the confluence of the Ohio and Mississippi rivers, about 37°. The east and west ranges of this district are from one side of the continent to the other, the barren districts excepted. In the eastern hemisphere, Brandt and Ratzeburg fix the northern range at 67°, and the southern at 36°.

Few animals present more interesting facts connected with their habits than beavers; but pharmacological lectures are not adapted for such subjects. I may, however, remark that these animals have been principally celebrated for the instinct (almost amounting to intelligence) evinced in the construction of their habitations, and in the building of dams to increase the depth of the water, and thereby to prevent its being frozen to the bottom. Hearne has published a good account of the beaver, and to his work, therefore, I must refer you for further information: as also to the 65th number of the Penny Magazine, for April 6th, 1835. It is a curious fact, that, when much disturbed, these animals change their mode of living: they no longer construct dams and houses, but merely burrow at the banks of the rivers; and, instead of living in colonies, they live isolatedly. We have evidence of this in America and Europe. The animals are then very absurdly called *Castor Terriers.*

The capture of beavers is effected in various ways: sometimes the animals are caught in traps, sometimes in nets. But the usual method is to break up the houses, when the animals retreat to their bank-holes, in which they are easily taken.

The physical properties of the castoreum of commerce next deserve our notice. Two principal kinds are described; one brought to us from America, by the Hudson's Bay Company, and another obtained from Russia. I was told, at the house of the Hudson's Bay Company, that the average annual importation of castoreum from America to this country, is about 2000lbs.; and of this quantity, at least 1600 lbs. are exported for continental use. The quantity of Russian castoreum brought into this country is very small.

1. *American castoreum.*—On the continent this is called *English* castoreum, because it is obtained through our merchants. It is also frequently termed *Canadian*, or *Hudson's Bay castoreum*, though these two last terms properly apply to distinct varieties.

American castoreum is that commonly, or almost universally, met with in the shops. It usually consists of two isolated sacs, frequently wrinkled, and which are connected so as to form two parts, like a purse, or like two testicles connected by the spermatic cords. The size of the sacs is liable to considerable variation. They are elongated and pyriform. The penis or the oil sacs, or both, are sometimes attached to them. The colour and other external characters are variable. In December, 1834, I examined between three and four thousand pounds of castoreum, which was offered for sale by the Hudson's Bay Company. A considerable quantity of it was covered externally with a bluish white mouldiness, while the remainder was of a brownish colour. The brown colour, however, varied considerably; sometimes being dark, in some cases yellowish, or even reddish. Some castor sacs are found nearly empty, and present, in their dried state, a very fibrous character: these are of inferior quality. Others are found gorged with unctuous matter, and, when quite dry, break with a resinous character, presenting no fibres until they have been macerated in spirit of wine. In many well-filled sacs the castoreum is quite soft.

In English commerce, two varieties of American castoreum are made: one called the *Hudson's Bay*, the other the *Canadian* castoreum. Both are imported by the Hudson's Bay Company. The *Hudson's Bay castoreum* is usually considered the finest variety. The specimens of it which I examined at the house of the Company, in December 1834, come from York Fort, and Moose River. The finest were cer-

tainly superior to any of the Canadian kind, though the average quality was much the same. Jobst has described a third variety, which he calls *Missouri castoreum:* it was of good quality.

2. *Russian Castoreum.*—Most pharmacological writers distinguish a kind of castoreum under the name of *Russian, Siberian, Polonese,* or *Muscovite* castoreum; and in the London Pharmacopœia we are ordered to employ Russian. This substance, however, is exceedingly rare, fetching a very high price, while its medical properties are not superior to those of the American kind. The specimen which I here show you cost me 2*l.* per ounce, while the finest kind of American castoreum may be bought at about the same sum per pound. In France, also, it appears to be still scarcer, for Professor Guibourt acknowledges that until 1831 he had never seen it. Forty ounces of it were, in that year, brought to Paris, from Moscow, and the price asked was 80 francs (that is, 3*l.* 4*s.*) per ounce; but, with the exception of half an ounce purchased by Guibourt, none of it was sold.

I have met with no description of Russian castoreum which precisely agrees with the specimens before us; but the best account is that given by Geiger, in his *Handbuch der Pharmacie.* The following are the principal characters (as far as I have ascertained them) by which it is distinguished from the American kind.

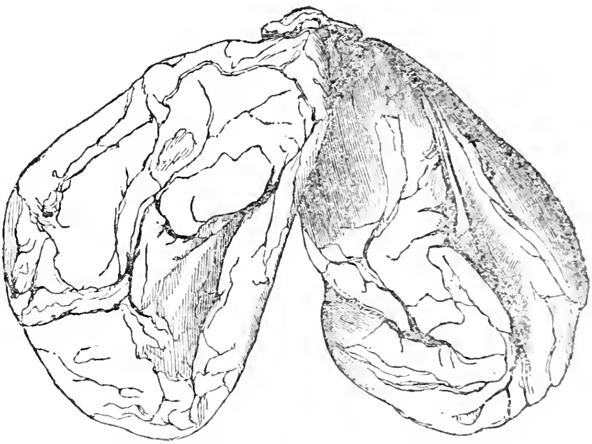

FIG. 41.—*Russian Castoreum.*

The sacs are *smaller* and more rounded than the American: they are compressed. The specimen before us, consisting of a pair of these sacs (fig. 41, natural size), weighs 557 grains. The specimens which I have seen had neither penis nor oil sacs attached; but Geiger says the latter are sometimes present. The colour is ash-brown. The odour is remarkable and peculiar, and instantly distinguishes it from the American kind. I should describe it as being empyreumatic: some persons have compared it to the odour of Russian leather. The internal appearance of the sacs is very different from that of American castoreum: the colour is brownish fawn, and quite dull, not having the least shiny or resinous character. American castoreum softens under the teeth like wax, and has an acrid taste; whereas Russian castoreum breaks down like starch, at first has little taste, then becomes somewhat bitter and aromatic. One of the most striking distinctions between the two kinds is, dropping a piece, about the size of a pea, into dilute muriatic acid: no obvious effect is produced on the American, whereas the Russian castoreum effervesces apparently as much as if you had dropped a lump of marble into this acid. This effervescence arises from the large quantity of carbonate of lime present. [The experiment was here shewn.]

The tincture of Russian castoreum, formed by digesting one part of this substance in sixteen of alcohol, is of the colour of deep sherry wine; whereas that made with American castoreum is nearly as dark-coloured as London porter. When added to water, the former produces a very slight milkiness only, and which is hardly altered by caustic ammonia; the latter, however, renders the water very milky, and when I add ammonia, a bright yellow-coloured liquid is obtained. [The experiments were performed, and the results shown.] The aqueous de-

coction of Russian castoreum is yellower than that of the American. Tincture of galls produces, as you see, no marked effect on either: the tincture of muriate of iron renders them both slightly turbid, and gives them a greenish tinge.

The castoreum mentioned by Guibourt, under the name of Russian, I have never

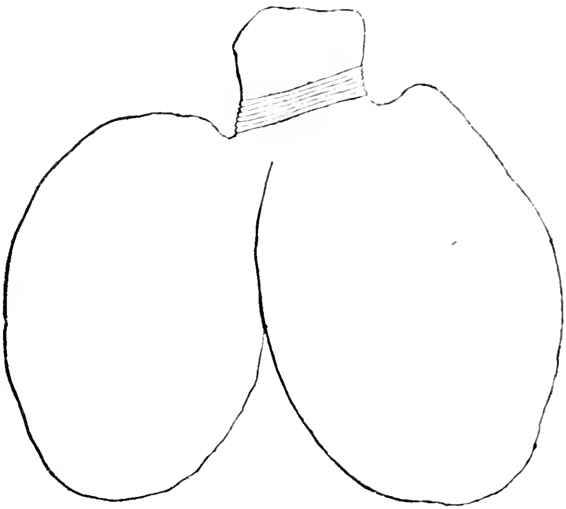

Fig. 42.

seen (fig. 41). It is evidently a different substance from that which I have described. The pods were full, rounded, broader than they were long, and didymous, or formed of two pods blended into one. Out of the whole forty ounces imported, only one specimen consisted of two ovoid pods, separated to the extent of three-fourths of their length (fig. 41). It seemed to have undergone some preparation: it hardly coloured alcohol, not only because it furnished little soluble matter, but because it wanted the colouring matter.

Chemical properties of Castoreum. — The most important substances in castoreum for me to notice, are the *resin*, the *volatile oil*, and the substance termed *castorine.*

1. *Volatile oil.* — Bonn states, he obtained 34 per cent. of volatile oil from Russian castoreum; but there must have been some error. Brandes obtained only one per cent., which I think is about the average quantity. By distilling the same portion of water several times, with fresh quantities of castoreum, we obtain a small quantity of oil, having a pale yellow colour, the odour of castoreum, and an acrid bitter taste. Here is some *aqua castorei*, holding a little of this oil in suspension. It is now nearly two years since I prepared it, yet it is apparently unchanged.

2. *Castorine.*—Boil castoreum in alcohol, and filter while hot. As the liquid cools a slight turbidness is observed, and a crystalline fatty matter is deposited, which has been denominated castorine. I have sometimes obtained it by boiling castoreum in pure æther: the castorine readily dissolves, while the resin remains undissolved. Russian castoreum yields a much larger quantity than any specimen of the American kind I have tried; but I do not think that even in this it would amount to one per cent. [Castorine obtained from the two kinds of castoreum was shown.]

Castorine was regarded by Fourcroy as adipocire; by Berzelius it is considered as nearly allied to æthal; by Gmelin it is considered analogous to the concrete volatile oils, and is termed *castoreum camphor.* It is a crystalline, fusible, non-saponifiable, fatty matter. In the liquid state it floats on water; when pure, is quite white; it is soluble in æther and in boiling alcohol. By long-continued boiling with nitric acid, it is converted into *castoric acid;* a yellow crystalline substance, soluble in water. This acid combines with ammonia to form a yellow, crystallizable, super-castorate of ammonia, which precipitates the salts of silver, lead, and of the protoxide of iron, white, and the salts of copper green, but does not throw down the salts of barytes, strontian, lime, or magnesia.

3. *Resin.*—If we digest castoreum in

rectified spirits of wine, we dissolve out the resinous matter. You will observe that when I add a little of this mixture to water, there is produced a milkiness, owing to the deposition of the resin. If this tincture be evaporated, we obtain a dark-brown extract (impure resin), which is to be washed with boiling water, and then redissolved in a little cold alcohol (by which some urate of lime and potash is separated). By evaporating this solution we obtain the pure resin. Here is some of it: it has a dark-brown colour, an acrid and bitter taste, and a slight odour of castoreum. It is insoluble in pure æther.

4. *Carbonate of lime.*—I have already alluded to the enormous quantity of carbonate of lime contained in Russian castoreum. Bonn states he obtained 24 per cent. I should think the quantity much larger. Buchner says that American castoreum contains $52\frac{8}{10}$ per cent. of chalk; and Brandes found $33\frac{6}{10}$. I have never seen any American castoreum which yielded any thing like this amount. For little or no effervescence is produced by dropping it into muriatic acid; and by incinerating 60 grains of good American castoreum in a platinum crucible, placed in a muffle, I obtained only $1\frac{2}{10}$ grains of ashes. Now if the whole of these were lime, and existed in castoreum in combination with carbonic acid, the quantity of chalk would be very little more than $3\frac{1}{2}$ per cent. Buchner mentions, in one pair of castor sacs he found stony concretions composed of

Fatty wax (castorine?) and resin	6·9
Extractive matter, with salts (sulphate and muriate of lime), and an organic acid	2·6
Volatile oil, animal fibre, and water	27.7
Carbonate of lime	52·8
Phosphate of lime	10·0
	100·0

5. *Other constituents.*—I have very little to say respecting the other constituents of castoreum. *Water* constitutes nearly 24 per cent. of this substance: *ammonia*, about 1 per cent. The presence of *urates* and *benzoates* (*urobenzoates?*) in this secretion, is a remarkable circumstance. Other substances, described as constituents of castoreum, may perhaps belong rather to the coats—such as *albumen* and *osmazome*.

Analysis of Russian Castoreum, by Bonn.

Æthereal oil	31 (?)
Fat (castorine?) with resin	23
Carbonate of lime	24
Cellular tissue	19
	100

Analysis of American Castoreum, by Brandes.

Ætherial oil	1·00
Castorine	0·70
Castorine (with carbonate, urate, and traces of benzoate of lime)	0·35
Resin	12·25
Resin (with traces of benzoate and urate of lime)	1 60
Albumen (with traces of phosphate of lime)	0·05
Osmazome (with traces of lactic acid and salts)	0·20
Mucus	2·30
Animal matter	2·30
Carbonate of lime	33·60
Phosphate of lime (with organic matter)	1·40
Carbonate of magnesia	0·40
Sulphates of potash and lime, and phosphate of lime	0·20
Carbonate of ammonia	0·82
Skin	19·20
Loss, water, &c.	22·93
	100·00

This analysis does not agree with the results of my experiments on *American* castoreum. I find a much smaller quantity of carbonate of lime, but a larger portion of resin, than is here stated. If it were not distinctly said to be the American kind analysed, I should have supposed, from the results, that it were Russian.

Physiological effects. — More than two thousand years ago, we find castoreum classed among medicines "quæ ad uterum faciunt." For many years past, however, its uterine effect has been doubted, and in this country is now for the most part disbelieved. By some writers it is asserted that castoreum causes a sensation of heat in the stomach, and accelerates the pulse; and hence it is called a stimulant. A soothing or narcotic effect has also been ascribed to it.

In the year 1768, Mr. Alexander, of Edinburgh, undertook a series of experiments, in order to determine what are the real effects of this substance. He tried it on himself in various doses to the extent of two drachms; and the only effect he could discover was the production of eructations. It neither raised the temperature of the body (as determined by applying the thermometer to the pit of the stomach), nor increased the frequency of his pulse. Alexander therefore concluded, that if this drug possess any virtue, it should be given in much larger doses than is usually done.

In the year 1825, J. C. G. Jörg, Professor of Midwifery in the University of Leipsic, undertook a series of experiments to determine the effects of certain energetic

medicines. For this purpose he established a kind of society, on the members of which the substances were tried. It consisted of twenty-two physicians or students, the youngest being 21, the eldest (Professor Jörg), 45 years of age; two lads, one 14, the other 16 years old; and three females, one 45, a second 18, and a third 12 years of age. One of the substances tried was castoreum. The results were as follows:—

In doses of from five to twenty grains the only effects produced were disagreeable eructations. The experiments were tried on the members (including the three females) most susceptible of the action of medicines. On the females not the slightest effect was produced. Professor Jörg took half a drachm fasting, and in an hour repeated the dose; but the only effects produced were disagreeable eructations, with the odour of castoreum (which were not allayed by breakfast or dinner, and only ceased at night when sleep came on), and a slight uneasiness in the epigastric region. The appetite, the circulation, and the respiration, were unaffected. The results of these experiments, then, agree with those of Alexander, made nearly sixty years previously; and notwithstanding that they are opposed to the statements of some other writers, I am disposed to adopt them, because, in the first place, in both cases the experiments were made with the greatest possible care; secondly, though made in different countries, and at distant periods, the results agree precisely; and, thirdly, they accord with the experience of most medical men.

But if we admit the accuracy of the above experiments, and adopt the conclusion of the feeble action of castoreum in the healthy condition of the body, we have no right, it has been said, to transfer this conclusion to morbid states. Cinchona bark, which has such a powerful influence over the system when suffering from intermitting fever, has comparatively a slight effect in the healthy state. If I were to judge from my own experience, I should say castoreum has very little therapeutic power, for I have not seen much benefit from its employment in those cases to which this remedy is said to be adapted. On all practical points I place great reliance on the experience of Dr. Cullen. Now he declares that, when given in large doses, castoreum is certainly, on many occasions, a powerful antispasmodic.

It appears that the odorous particles of castoreum are absorbed, for they have been detected by their smell in the urine.

In classifications of the materia medica, we find castoreum sometimes called an antispasmodic; sometimes a stimulant, or excitant; at other times it is said to be a tonic, or nervine-tonic. Barbier thinks it has a specific influence over the brain, spinal marrow, and great sympathetic system; and hence the power which he asserts it possesses of relieving some diseases called spasmodic. Vogt asserts its principal operation to be on the ganglionic system, while its action on the spinal marrow is much less, and on the brain scarcely any. The facts which I have already detailed show that we have very little positive information regarding the action of castoreum, and, therefore, that many of the assertions just alluded to are for the most part hypothetical.

Uses.—Castoreum was formerly in great repute in those affections of the nervous system denominated spasmodic, such as hysteria, epilepsy, and catalepsy, more especially when these diseases occurred in females, and were attended with uterine disorder. In those forms of fever called *nervous*, this medicine has also been recommended. In the northern parts of Europe it is used to promote the lochial discharge, and the expulsion of retained placentæ. It is, however, little employed here, partly, perhaps, in consequence of its disagreeable taste and smell, its variable quality, and its high price; but for the most part, I believe, because practitioners consider it an almost inert remedy.

Mode of exhibition.—If you use castoreum, always give it in substance, either reduced to powder, or made up into pills. The dose should be at least one or two drachms. The *tinctura castorei* of the London Pharmacopœia contains only one drachm of castoreum to one fluid ounce of rectified spirit, so that two fluid ounces would be required for a dose, if we considered the castoreum only. The quantity of castoreum, therefore, is much too small.

ABSTRACT OF CASES

RELATING TO

SEVERAL MODES OF OPERATION FOR ERECTILE TUMORS.

By F. Lallemand,
Professor at Montpellier.

The following remarks on the treatment of Nævus, by Professor Lallemand, are extracted from the Archives Générales de Medécine, tom. viii. Serie ii. The plan proposed is, in principle, and almost in itself, the same as that first related in this journal* by Dr.

* Vol. vii. p. 677.

Marshall Hall. M. Lallemand leaves his needles in the tumor; Dr. Hall repeats the acupuncturation, and leaves in the threads: the object of both is to induce inflammation — to substitute cicatrix for erectile tissue. The process is *slow*, and hence the supposed *difficulty* in the cure; for there appears to be none if time be given, and the operations, which are neither attended by pain nor hæmorrhage, be duly repeated.

Case I.—*Tumor of the Gum—Excision fruitless—Trephine and actual Cautery successful.*

Etienne Beloux, nine years of age, and of a strong constitution, entered the hospital of Saint Eloi, January 17, 1833, for a fungous tumor of the gum of the lower jaw, extending from the last right incisor to the first large molar on the left side; with loss of the small molar, the canine, and the two incisors of the left side. The tumor, which was two inches long and one inch in height and in thickness, was indolent, of a deep violet colour, mammelated at its surface, of a soft consistence, and fluctuating. The slightest pressure indented it, and rendered it pale, though it immediately recovered its volume and colour. The portion of the lower lip corresponding to the middle part of the tumor, was of a violet-red colour, and traversed by very distinct and varicose vessels.

Excision and cauterisation had been tried three times in the space of two years; on each occasion the disease had increased, and for some months had made rapid progress.

On January 25th, the face being exposed to a strong light, I divided the lower lip by an incision, commencing at half an inch from the left commissure, and reaching to the under part of the jaw. I then made another incision, perpendicularly to the former, near the inferior border of the maxillary bone. The two upper strips of this crucial incision were dissected back, and kept apart by a contrivance which compressed the labial arteries. I then applied the trephine to the two upper layers of the surface of the maxillary bone. I cut off, with the curved scissors, the portions of the mucous membrane which were highly injected and varicose, and concluded by applying the white-hot cautery to those parts of the bone, or gums, which I had reason to suspect. The two upper strips of the lip were united by three needles and the twisted suture, as in hare-lip; the lower strips were brought together by two fastenings of the common suture.

On the 30th the union was complete, and in a few days more there were no signs of the incisions. On the 10th, a curved or semicircular plate of bone was extracted. Cicatrisation proceeded regularly in the interior. The patient continued a month at the hospital, and all went on well; the second teeth proceeded to grow, the face was perfectly regular, and the mastication unattended with any pain.

Case II.—*Nævus of the Upper Lip removed by Incision and the introduction of Needles.*

George Fischer had, from his birth, a red spot, of the size of a large lentil, on the middle of the upper lip. As he grew up, the spot increased, and gradually extended to the partition of the nasal fossæ, and to the interior of the nostrils.

On the 5th December, 1832, the patient entered the hospital of St. Eloi. He was then five years and a half old. The upper lip was red, thick, prominent, and extended over the lower about an inch. The swelling and redness terminated insensibly towards the commissures, and extended upwards to the mucous membrane of the nostrils. All these parts were soft and elastic, and turned pale upon the slightest pressure, but quickly resumed their colour. The swelling rapidly increased, from impatience, irritation, crying, &c.

After due consideration, I came to the following conclusions: — Accidental erectile tissue is only morbid in reference to its seat, inasmuch as it resembles in its organization the tissues which occur in the normal state: it has the same properties, and would accordingly be similarly affected under similar circumstances. On the other hand, lesions of the common erectile tissues are capable of cure by means of a cicatrix—a mode of treatment very injurious to the functions of the organ, as is plainly observed to result from wounds or lacerations of the corpora cavernosa, or spongy tissue of the urethra: the penis, during erection, bends towards the injured part, the inflammation having there substituted a harder tissue than

previously existed; or, in other words, the erectile tissue having been replaced by the fibrous.

Why should not the accidental erectile tissues be also capable of inflammation, of reunion, and of a similar change?

In the case of Fischer, the erectile tissue of the lip was perfectly soft and elastic, resembling, in this respect, the corpus cavernosum in its most healthy state. On the 24th December I removed, from the middle part of the fungus, a slip, from eight to ten lines in width at its base, by two cuts of the scissors converging towards the partition. Blood gushed out vehemently from numerous vessels, and the slips, immediately sinking down, assumed instantaneously the volume and nearly the ordinary colour of the lip. They were immediately seized by the fingers of several assistants, and the hæmorrhage was presently stopped. I quickly united the two slips, by four needles fastened at a distance from the wound, and passing through its entire substance. After the insertion of each needle, a waxed thread was employed to bring the lips of the wound together, and all loss of blood arrested by uniting the divided surfaces face to face: the space between the needles was occupied by numerous twistings.

On the following days there were *red* and painful swelling of the parts adjoining the wound, fever, and headache; but not a drop of blood was lost. On the third day, profuse epistaxis reduced the inflammation, and caused the fever to subside. On the fourth, I withdrew the two upper needles, leaving the threads in their place. On the fifth, I removed the remaining two needles: there was a slight discharge of blood and pus from the punctures, which continued for some time. On the eighth, the swelling of the lip and nose was sensibly decreased. On the 25th the threads were detached, presenting to view a solid deep cicatrix, drawing the loose edge of the lip five or six lines towards the partition of the nasal fossæ.

These changes took place *slowly*, but *continued several months after the operation.* The upper lip recovered merely its regular volume, and no longer lay over the lower one; all the parts involved in the operation were *changed* into a kind of *fibro-cartilage.*

Yet the partition of the nasal fossæ remained tumefied, and also the adjoining mucous membrane: this was, however, to be expected, as these parts were not included in the operation.

After the effect produced by the needles, on the parts into which they had been inserted, I thought of passing several of them through the partition, to excite inflammation and the subsequent formation of as many cicatrices. The first of these needles passed readily through the cartilage; but those which I attempted to insert beneath, were prevented from entering by the cicatrix, and were bent like a fish-hook. This occurred on both sides; showing that the median cicatrix was harder than the partition of the nasal fossæ, and fully justifying the principle of the treatment.

Fifteen days after the application of these needles, a cartilaginous substance, like a lentil-stone, was felt in the track of their insertion. I applied others in the intervening space, and a similar change ensued. It would undoubtedly have extended further had the inflammation been more acute; but I was obliged by the patient's uneasiness to withdraw the needles after two or three days.

Case III.—*Nævus of the Cheek in an Infant treated similarly with success.*

Jean Amédée was observed to have, at her birth, a reddish spot about the middle of the left cheek, about three lines in diameter, and slightly prominent; its surface had the appearance of a raspberry; it became tumid and livid as soon as the infant cried. Its increase was rapid.

In the beginning of July, 1834, I made an incision into the tumor through its whole substance, and in the direction of its greatest length. I immediately united the two lips of the wound with four needles, which were kept in their places by numerous twistings of waxed threads.

On the next and following days the portions of the tumor which were unoccupied with the threads were considerably swollen, and became of a deeper and deeper violet colour; the surface was tense and glossy.

On the fifth day I removed the needles. Some drops of blood flowed, mingled with pus; this discharge continued several days through the holes of

the needles, forming an incrustation with the threads, of a volume and hardness which kept increasing. In about fifteen days this incrustation separated, exposing a cicatrix marked by the holes of the needles, which continued to suppurate for a long time.

The small wounds were frequently cauterized with the nitrate of silver, and the appearance of the surface gradually changed its character. The parts which had not been incised or pierced by the needles sunk down, and assumed a less deep, and afterwards a rosy, colour. In proportion as the cicatrization of these small seats of suppuration advanced, the adjacent parts spread, and became more and more free from colour. Finally all these cicatrices hardened in time, presenting only a pale, uniform, glossy surface, like those of the regular thin cicatrices which follow after a superficial burn of the skin.

In *five months* there only remained of the erectile tumor some red spots about the circumference, at too great a distance from the seat of inflammation to have experienced its effects. They became more pale and depressed, and would, perhaps, have disappeared. I then pierced them with very fine pins, and the inflammation thus produced transformed them into fibrous tissue. The whole of the cicatrix is thin, pale, and tense, like that of a burn.

Case IV.—*Nævus of a large size over the Scapula — Inflammation excited by the introduction of* 120 *pins — Cure.*

Dolores, of Villa Parma, an infant of very delicate constitution, was born with a red spot, about an inch in diameter, near the middle of the left shoulder-blade. It increased rapidly. In three months it was about three inches in length and two in breadth, and projected from the surface of the skin more than three lines. Its surface was like that of a raspberry, which it also resembled in colour. Compression had been tried in vain.

I applied a corset and pad; and in the beginning of December, 1834, I applied a dozen fine pins to the inferior extremity of the tumor, and covered the spaces between them with numerous twistings of waxed thread. The child cried but little, and was soon quieted. Three days afterwards I performed the same operation on the opposite side of the tumor. I operated in a similar way upon the whole circumference of the tumor, leaving the pins in their places until they had produced sufficient inflammation, *i. e.* seven or eight days or more.

In forty days the whole circumference having fallen, or being in a state of suppuration, I proposed to proceed in the same way with the centre, when I observed that it was livid, tumefied, and very hot. The health of the child was rather deranged, and I waited in consequence a few days. But, *to my great surprise*, I observed the parts which had been subjected to the previous treatment gradually suppurate, or shrink and become pale; so that in fifteen days the erectile tissue of this central part was completely changed into a flat and uniform cicatrix, of about two inches in extent.

It remained for me now merely to operate upon several points of the circumference, which had escaped the inflammation produced in the adjacent parts.

In two months and a half of this treatment the tumor had entirely sunk down; nine-tenths of its extent were replaced by a uniform and glossy cicatrix, which became every day of a paler hue. The parts which were last operated upon alone presented a degree of prominence and redness; they, however, shrunk, and acquired such a consistence that fibrous tissue formed along the track of the insertion of the needles.

In the course of the two months and a half 120 pins were inserted, yet not a spoonful of blood was lost; and the little patient, so delicate in health, was only slightly indisposed for two or three days.

It is also remarkable that the central part of the tumor, which had not been traversed by a single pin, partook of the inflammation of the adjacent parts, and underwent the same change.

Remarks by M. Lallemand.

These cases show that acute inflammation of the accidental erectile tissues, by whatever cause it is produced, is sufficient to effect a cure.

Without endeavouring to explain how this vascular net-work continues to extend itself, sometimes with excessive rapidity, from the part first affected to the adjacent parts, it is evident from

what has gone before that the inflammatory congestion deposits, in the first instance, gelatino-albuminous fluids in the meshes of this vascular net-work; and that, the water which held them in the liquid state being absorbed, they became thick, and continually denser, assuming the form of a new tissue of a harder kind, and consequently more impervious, than that which previously existed.

This principle explains the livid swelling, softening, and suppuration, which occur in the first period of the treatment, and the unexpected results which successively take place in the second.

As absorption continues to act upon these materials for a long time, with an energy decreasing as the matters become less aqueous, it takes a considerable time to ascertain the entire result. The longer the operation has been performed, the more favourable is the aspect of things.

The preceding cases point out a mode of cure, when compression is out of the question, and entire removal of the affected parts dangerous; and when entire removal is unattended with danger, but is likely to produce serious deformity, the means suggested are unattended with danger, or even acute pain.

The most effectual mode of producing inflammation of a diseased part is undoubtedly *acupuncturation*. The following are the results of my own observations on this subject.

I at first used very fine sewing-needles, with a view to introduce them more easily; but they are very inconvenient, as they can be neither cut nor bent, and must therefore be kept in their place for a long time. The erectile tissues are so soft, that it was easy for me to replace the needles by very long and fine pins, such as are used for fixing small insects; these are made to enter in every direction without any difficulty, and they can be easily cut with common scissars, or their extremities bent with pincers; they are very easily managed, and in every respect most convenient.

Finally, we should never forget that inflammation is the essential agent in the change which is induced, and that it always brings on this result, if sufficiently acute, whatever means may be employed to excite it, or to raise it to the proper degree.

A CASE OF

LARGE TUMOR REMOVED FROM THE SCAPULA.

By Henry Earle, Esq. F.R.S.

(Read before the Royal Medical and Chirurgical Society, Tuesday, Nov. 10, 1835).

The following case, which occurred lately at St. Bartholomew's Hospital, may perhaps, from its novelty, possess sufficient interest to deserve the attention of the Fellows of the Society:—

James Jackson, ætat. 55, by trade a comb-maker, was admitted on the 10th September, in consequence of a large tumor situated beneath the left scapula. He stated that about thirteen months previously his attention had been first called to it in consequence of the pain which he experienced in the left shoulder, which extended down his arm. About ten weeks before his admission he perceived a swelling under the scapula, which gradually increased up to the time of his admission. It had by that time acquired the size of an ostrich's egg, and was situated immediately beneath the scapula, extending beyond the base of that bone about three inches, towards the spinous processes of the dorsal vertebræ. It partook of every motion of the scapula, and was evidently in contact with it. The patient was still able to move the arm and shoulder, when the whole tumor moved freely on the surface of the ribs. He had been a very free liver, and his general aspect was bloated and unhealthy.

The base of the scapula could be distinctly traced, and, as far as could be ascertained, no absorption or alteration of structure had taken place in that bone. A cast was taken of the tumor, and it was accurately measured.

Leeches were applied, his arm was kept quiet in a sling, and his general health was attended to. From week to week the tumor perceptibly increased, and he suffered constant pain down the arm.

Several consultations were held on the case; but the nature of the tumor, and the extent of its attachment to the scapula, could not be satisfactorily ascertained, which led some gentlemen to negative any operation, from an ap-

prehension that it might be malignant, and that it would probably require the removal of the greater part of the scapula. On an attentive consideration of all the circumstances of the case, I was induced to entertain a more favourable opinion; and as the patient was very anxious to undergo any operation, I undertook to perform it.

The circumstances which influenced my opinion were the healthy state of the integuments over the tumor, and the apparently natural condition of the outer surface of the scapula, which would, I conceived, have been included in the disease, and have undergone some change in the course of thirteen months, if the disease had been malignant. The tumor was smooth and regular on its surface, and very firm, having no feeling of elasticity like fungous disease. But the circumstance which weighed most with me was the fact that the serratus magnus anticus could be put in action, and its several digitations could be distinctly felt at the side of the chest. From the situation of the tumor it was certain that the fibres of this muscle must pass round the whole mass to be inserted into the base of the scapula, and that the tumor must be situated between this muscle and the under side of the scapula. As this muscle was still capable of being put into full action, I inferred that it could not have acquired any intimate connexion with the tumor, and I entertained hopes that the latter might not have formed any very firm adhesions with the scapula; and that, although it was in great part covered by that bone, still it was not any morbid growth proceeding from it, an opinion which the natural condition of the upper surface of the bone appeared to warrant.

On Saturday the 3d of October, having fully stated all these circumstances, I proceeded to perform the operation, with the understanding that, if found to be necessary, any part of the scapula that might be included in the disease should be removed. I made a very free lunated incision from above the spine of the scapula round the base of the tumor, to below the inferior angle of the scapula. The integument was dissected up towards the scapula. The trapezius and the two rhomboids were successively divided and reflected. The fibres of the serratus magnus then came into view, being greatly elongated and spread out over the tumor. I next divided these near their insertion into the base of the scapula. On endeavouring to detach the tumor from beneath that bone, I found it firmly connected near the inferior angle, but readily separable beyond this part. It was only necessary to divide a few fibres of condensed cellular membrane, and with my finger and the handle of a scalpel I succeeded in removing the whole tumor, with the exception of a small portion near the inferior angle, which I cut through and subsequently detached without difficulty, as it was only connected with the bone in consequence of its having caused a small circular part of the bone to be absorbed at this part, to the extent of half an inch, through which the tumor had made its way; but it was readily drawn out, leaving the bone bare and rather rough. A small projecting spicula of bone was removed with the forceps.

Nearly the whole of the subscapularis muscle had been absorbed, leaving the bone bare, but quite healthy, with which the tumor was in contact. The part where the bone had been absorbed had been crossed by the latissimus dorsi, and had been subjected to more pressure from that circumstance. It was only necessary to tie two arteries, and the wound was approximated, leaving sufficient space for the escape of any discharge. A compress and bandage were applied, and the arm fixed to the side. Not a single unfavourable circumstance occurred; the greater part of the wound healed by the first intention; very little suppuration followed, and the patient quitted the hospital quite well on the 4th of November, having recovered the use of the arm and shoulder.

The above case I consider very satisfactory and instructive, in proving the value and correctness of reasoning on anatomical facts, as certainly I was principally induced to undertake this apparently formidable case from the circumstances which I have mentioned of the free action of the serratus magnus. When the whole of the tumor was removed, the fibres of that muscle could be distinctly seen, forming a muscular pouch or cyst, which had surrounded all the inferior and outer surface of the tumor. When examined, the tumor was

found to consist of a structure much resembling the intervertebral fibro-cartilage, but in some parts it appeared more vascular, and somewhat softened. Mr. Kiernan considered it to be a specimen of albuminous sarcoma.

IMPALEMENT ON A BROOM-SHAFT.

To the Editor of the Medical Gazette.

SIR,

THE perusal of a case, related by Mr. Ilott, in No. 4 of your periodical, induces me to forward a condensation of the notes of a similar one, which is at your disposal.—I am, sir,

Your obedient servant,
CHAS. COTTON, M.R.C.S., &c.

Lying-in Dispensary,
Nov. 14, 1835.

—— Woods, æt. about 50, by trade a broom-dasher, fell a distance of several feet upon a broom-shaft, standing in a perpendicular position, the point of which entered the scrotum between the testicles to the right side, passing up beneath the abdominal muscles to at least three inches above the umbilicus. The shaft, owing to its tough nature, was not broken, but bent, so that one extremity was extended upon the abdomen, whilst the other was firmly imbedded apparently in the sheath of the rectus beneath the muscle. Much difficulty was experienced in its extraction, and slight hæmorrhage followed.

The very exhausted state of my patient required the administration of a slight stimulus and application of warmth. In the evening symptoms of great constitutional excitement followed, together with pain of the abdomen, and in the course of the injury, which was marked by a red streak. These were combated by bleeding, a large dose of calomel and opium, salines, leeches applied over the red line caused by the accident, followed by fomentations and poultices to the wound, which afterwards suppurated kindly, and in five weeks my patient was well,—a circumstance unanticipated, when I state the man to have been given to very irregular habits, and the extent of wound, its adjacency to the peritoneum, &c. are taken into consideration. I was called to the man shortly after, he having, in a fit of inebriety, committed suicide.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

HYGIENE OF PRISONS AND WORKHOUSES—PRIVATION OF FOOD.

THE Commission appointed by Parliament for inquiring into the state of our prison discipline, will bring to light, we doubt not, some extraordinary facts. Were its labours further extended to an investigation of the discipline and regimen observed in our workhouses, we are no less satisfied that the result would prove somewhat startling to the nation. We have heard strange stories of both. There are jails in which it is the regular rule to keep all prisoners on bread and water, *even previous to trial;* and there are workhouses where the diet is so miserably insufficient, that the wretched inmates are sometimes obliged to commit crime, in order to have themselves transferred to a prison where they may have a better chance of sustenance.

If examples of this sort be found not unfrequent amongst us—and we cannot refuse credence to the instances just referred to, they having attained some considerable share of notoriety—what must be thought of the legislatorial wisdom that has directed or permitted such an order of things? The Judges of Assize are, we believe, entrusted with the regulation of prison discipline, in so far at least as relates to the dietetic treatment of prisoners, even in cases where the latter have been merely committed, and are not yet brought up for trial. But who has given power to the managers of workhouses to maintain a starving regimen among the paupers committed to their charge? A modicum of bread, and sometimes a little cheese, are

scrupulously weighed out to each pauper: the *same* quantity for each and for all; and this is to be swallowed with the aid of cold water, of which, no doubt, the poor wretches are munificently allowed to take as much as they please.

The system somewhat varies, we are told, in different parishes; but what can we expect, when even in the workhouse of St. James's, a pauper is driven, by the necessity of sheer hunger, to break windows, that he may be committed to a house of correction? Such an instance occurred very recently; and it came out in the investigation before the magistrate, that the statement of the starving wretch was not to be contradicted.

In the greater number of parish workhouses, it may be said, the system is different: the inmates get a sufficiency of wholesome but plain—very plain, food; they get soup—not wholly destitute of the flavour of meat. By such statements as these, however, the general position is only strengthened; and all we want to know is, why in any instance there should be a power of starvation vested in any individual or set of men?—a power the more dangerous, and the more likely to be cruelly abused, when we observe the unwillingness with which admissions are daily granted to those abodes of despair. If there be an interest in excluding paupers as long as possible from within the walls, why may we not suspect an interest also in getting rid of them when once admitted? The inference is inevitable.

We have had occasion frequently of late to call attention to the treatment received by *sick* paupers from the authorities who have the power, but not the will, to procure them proper medical relief. It seems that in sickness or in health the case is the same; and, strange to say, in this country, which boasts of its legal provision for the poor, we are doomed to witness a degree of tyranny exercised towards the pauper class which would disgrace the least civilized state in Europe.

There is no European state, we believe, with the exception of our own, in which the management of such matters is left to so capricious a destiny. Every country in Europe, but this, recognizes some hygienic arrangements or other, regarding its prisons and houses of correction. So far, however, as we have been able to gather, it has here been only a system of experimenting, in the different pauper and prison establishments, on how scanty an allowance of food the miserable wretches may remain alive: if they barely escape apparent death from starvation, the purpose seems to be answered; no matter even if cachectic diseases should make their appearance. The result of the experiments made on the paupers at the Millbank Penitentiary, a few years ago, is on record: a decoction of beef-bone, called soup, diluted to the extent of about 100 quarts from a single ox-head *, was administered for a time,—but the consequences were alarming. It was unluckily found to give rise to an epidemic among the prisoners; they were seized with general debility of body, with emaciation, and an eruption resembling sea-scurvy. Upon altering the plan of diet, however, the effects ceased. It might have been thought that the public investigation which led to the exposure of these facts would have put the experimentalists upon their guard; but the reverse seems to have been the case: *we shall see*, at all events, when the parliamentary commission shall have closed its labours, and given us a report.

* The Regulation literally ran as follows:—"The soup to be made with ox heads in lieu of other meat, in the proportion of one ox-head for about 100 male prisoners, and the same for about 120 female prisoners," &c.—Report, App. p. 368.

In connexion with this subject of the extent to which starvation may be carried, we cannot refrain from alluding to the valuable case of abstinence reported by Dr. Sloan, of Ayre, in the last number of this journal. It shows to those who are curious about the matter (our parish functionaries may look upon it as an experiment worthy of note) how long the oil may be withheld before the lamp of life is extinguished. We know not that we have ever met with a better example than this of the terrible effects of famine. Others there may be, perhaps, more showily narrated; but we question if any of them be more trustworthy. The celebrated case of Viterbi, of Corsica, for example, is more than apocryphal. It was drawn up, in the first instance, for general readers, and still continues to be referred to in certain books, as a complete case of determined suicide by abstinence. For above twenty days the murderer is said to have endured the tortures of hunger, and to have sunk at last through pure exhaustion. To the discomfiture, however, of those who cater for the lovers of romance, and who make so circumstantial a narrative of this wretch's last moments, it is now well ascertained that though he really abstained from food at first, he contrived to finish his career with a dose of arsenic—a fact legally authenticated by three medical men who were in attendance.

Perhaps the only other case of fatal abstinence worthy of being compared with Dr. Sloan's, is that related by M. Falret, in his book on *Suicide*. A tradesman, aged 32, in consequence of some reverses of fortune, resolved to starve himself to death. He accordingly, on the 15th September, 1818, withdrew to an unfrequented wood, where he dug his grave, and continued alive till the 3d of October following. At the latter date a chance passenger happened to light upon him, who, perceiving that he still breathed, eagerly lent him assistance; but the introduction of a little soup into the stomach proved fatal. Here was a case of abstinence proving fatal in *eighteen* days; and what renders it still more deeply interesting, is, that we have the details of the unhappy man's sufferings, kept by himself, in pencilled notes, up to within four days of his death. As we have noticed this case so far, perhaps we may as well subjoin some further particulars, briefly extracted from the journal, as given in the work alluded to. The curious reader will contrast the sufferings of the French and the Scotch victim, as well as the particular mode of enduring them displayed by each. It is to be remembered, however, that the Scotchman longed for life, while the Frenchman as ardently longed for death.

"In addition to the pains of hunger and thirst, the unhappy man had to endure those of cold and rain. On the night of the 16th he was soaked through, and during the following day and night was obliged to keep in constant motion, in order to resist the cold. His thirst forced him to lick the dew off some mushrooms which grew around him. By the 20th his hunger and thirst attained a frightful pitch: there had been no rain for the last three days. On the 21st he could not resist the temptation of running to an inn, about a league distant, where, for the last piece of coin in his possession, he bought a bottle of beer. This procured him but little relief; he determined, however, not to stay so far off from the inn in future, that he might at least in his agony taste pump-water. He tried this water on the 22d, but his stomach rejected it. Sleep was completely banished; he had not closed his eyes for the whole week preceding. His limbs now refused to bear him towards the inn: every day he expected to be his last; yet in the midst of his sufferings he did not neglect the insertion of some lines in his journal. Five days more elapsed, when, it seems, a shepherd saw him at a distance, but took no particular notice. Heavy rain came down

on the night preceding the 29th; some of it he received in his mouth; but, as he noted (in the last words contained in the journal), *water* could not now appease his tortures. What he suffered during the remaining four days can only be conjectured: it is to be hoped that during that time he was without consciousness * "

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 24, 1835.

HENRY EARLE, ESQ., F.R.S., PRESIDENT, IN THE CHAIR.

THERE was this evening a remarkably full attendance of members. Dr. Faraday and Mr. Clift were elected honorary Fellows. Two papers were read: the first was the *History of a remarkable Case of Varicose Aneurism*, from the pen of Mr. J. G. Perry, Surgeon to the Marylebone Infirmary. It was a case in which death ensued in six days after an operation for aneurism of the femoral artery, in consequence of the sac having communicated with the accompanying vein. We shall take another opportunity of laying fuller particulars before our readers.

Mr. ARNOTT having inquired as to the state of the posterior tibial artery, and being informed by Mr. Stanley and the author of the paper that this and the other arteries in the neighbourhood of the aneurism were apparently sound, proceeded to make some observations on the anomaly which the case presented from several others described by Breschet, Dupuytren, a writer in the Glasgow Journal, and one lately witnessed in the Middlesex Hospital—in all of which there was more or less of a venous condition about the coats of the arteries, being much thinner than natural, and having a strong tendency to collapse.

Dr. BURNE remarked on the perpetual whizzing sound noticed in Mr. Perry's case, that this ought to afford a diagnostic sign of some value in distinguishing between common and varicose aneurism; the former being attended only with the bellows sound, and that simultaneous with the contraction of the pulse.

Mr. MACILWAIN introduced some account of a case of bronchocele of a very large size at present under his care. He had not thought it expedient to tie the superior thyroid artery, as the President said *he* had done with success in a case under his care at St. Bartholomew's; but the application of a seton appeared to him (Mr. M.) most advisable.

The other paper read was *A Case of Recovery from the Insensibility of Intoxication, by the performance of Tracheotomy;* the author Mr. G. Sampson, of Salisbury. The stomach-pump had been employed in this case (above a pint of brandy and other liquors having been drunk); but still the patient became more and more comatose. It struck Mr. Sampson that this condition was owing to torpor of the brain, the blood sent to it not being sufficiently arterialized, owing to an inertness or inaction about the glottis. Tracheotomy was accordingly determined on, and performed, with speedy relief to the respiration: the patient gradually revived, and in a short time was quite well.

Mr. HOWSHIP related a case of insensibility and narcotism, from laudanum, which was ultimately restored by artificial respiration; and

The PRESIDENT narrated a somewhat similar instance, where insensibility and cessation of the pulse having been produced by too large a tobacco injection, administered previous to an intended operation for hernia, respiration was re-established by inflating the lungs, and sensibility presently restored.

A paper by Mr. Stafford, on *Wounds received in Dissection*, was deferred till the next evening meeting.—Adjourned.

The following is an abstract of Dr. Yelloly's paper, read at the meeting of the 10th instant:—

Observations on Vascular Appearances of Mucous and Serous Membranes, as indicative of Inflammation.

The author begins by recapitulating the chief points in a paper of his published in the fourth volume of the Transactions, upwards of twenty years ago. In that paper he treated of those vascular appearances in the stomach which are sometimes mistaken for inflammation. He touched also on the state of the villous coat of the intestines, and of their outer or serous covering, with reference to similar pseudo-morbid appearances. He endeavoured, in fact, to shew—

1. That appearances of vascular fulness in the lining membrane of the stomach, whether florid or dark-coloured, in distinct vessels, or in extravasations of different sizes, are not to be regarded as unequivocal marks of disease, inasmuch as they are not inconsistent with a previous

* This case was first published by Hufeland, in his journal, and introduced to French readers by M. Marc, in the *Bibliothèque Médicale* for Jan. 1820.

state of perfect health. 2. That authors were deceived who inferred from these phenomena that gastritis sometimes existed in the living body without symptoms, and who conceived it a puzzling circumstance that such unequivocal marks of violent inflammation should be found where there had been none of the usual concomitants of pain or pyrexia. 3. That Morgagni was wrong in attempting to account for the fact by supposing a paralytic affection of the parts, whereby the symptoms were masked; and Haller also, in fancying that almost every kind of fever was attended with inflammation of the bowels. 4. That erroneous conclusions as to the cause of death were frequently owing to the same mistaken observations—the effects of putrefaction, and the spontaneous changes induced by the loss of vitality, being sometimes attributed to the action of poisons. 5. That hydrophobia and some other obscure diseases were often subjected to an absurd treatment, owing to the same errors. 6. That the vascularity in question is entirely venous, and due to the tendency which even the arteries have to supply the veins at the close of life. 7. That transudation also contributes to those appearances. And 8. That the fact of inflammation having existed previous to death, cannot be inferred merely from the aspect of the vessels in the dead part: there must at least have been symptoms during life.

The same views, with very little modification, will apply to mucous and serous surfaces generally. But the state of the spinal marrow is not so commonly understood, it being seldom inspected unless for some precise object. The author thinks, that owing to this want of familiarity with the general appearances of the spinal cord, an erroneous notion has been conceived of the nature of some diseases—such as tetanus. With his former paper, the author gave a plate representing the appearances in the stomach of some criminals who had been executed: along with the present communication we have a drawing which affords an example of the state of the spinal marrow of a hanged man; the appearance is very vascular.

Some remarks are then made by the author on the importance of accurate investigation into the morbid phenomena in the body after death; and he draws a distinction between the appearances that belong to external and internal inflammation.

"The phenomena of redness, swelling, heat, and pain, sufficiently indicate the existence of inflammation in *external* parts, but in affections of internal organs we are often led to our conclusions by imperfect analogies, and by symptoms and appearances more or less doubtful. Sensations themselves are, to a certain degree, deceptive or equivocal. They may be connected with very different states of the body, and may be very dependent on the temperament of the patient by whom they are described. In internal diseases we are by this means often left to form our conclusions, as to the existence of certain states of disease connected with the extinction of life, by the appearances offered on examination after death."

The changes which occur in an *external* inflammation after death—the redness in general disappearing, and the tumor subsiding—are necessarily owing to the altered state of the blood-vessels, both arteries and veins having parted with their contents, and leaving the parts to which they belonged nearly exsanguous.

But in *internal* inflammations, especially of the abdominal viscera, various modifications take place. Being connected with the venous structures of the liver and heart, in which a considerable portion of the blood is concentred after death, an obstructing cause operates on the veins which belong to them, and this, added to their softness of texture, produces more or less of fulness of the vessels; and hence the appearance of vascularity both on the external and internal surfaces of the parts.

Previous to death, it rarely happens that this sort of accumulation takes place; so that vascular fulness in the dead body must be viewed with caution ere we take it for an indication of the state of things during life. As to the florid state of vessels, which has often been regarded as a proof of arterial congestion, it merely arises from the arterial character of the blood remaining in the veins for some time after its transmission from the arterial capillaries.

The author expresses his satisfaction at the spread of pathological knowledge, both at home and abroad, of late years; and more particularly at the adoption, by distinguished foreign authorities, of the views advocated by him in his former paper. Although Tommasini and Broussais, with their followers, may be opposed to those doctrines, yet Andral speaks decidedly of there being *various degrees of vascularity which are not to be regarded as inflammation.* Otto, in like manner, even cautions his readers against the opinions of Tommasini and Broussais, respecting redness of particular viscera as indicative of inflammation (Pathol. Anat. p. 47, English edit.) But perhaps Billard, in his Treatise on Mucous Membrane, and Rigot and Trousseaux, in the Archives Génerales, are the most energetic of the

foreign advocates who maintain these views.

In conclusion, Dr. Yelloly invites the attention of the Society to a beautiful drawing of a human stomach, accompanying his paper: it represents a pseudo-morbid appearance of a number of depressions of various sizes, which a superficial examination might ascribe to alterations, but which are found to be natural depressions followed by the mucous lining. The patient had no symptoms of stomach disease.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

Auscultatory Symptoms—Rhonchus and Sibilus—In what sense they are Dry Sounds—Where and how Rhonchus is produced—Occasional Rhonchus—Permanent Rhonchus—Where and how Sibilus is produced—Diseases in which Sibilus occurs—Chronic Bronchial Diseases more or less inflammatory—Asthma—Peculiar forms of Acute Bronchial Inflammation.

I HAVE mentioned a few auscultatory signs, Rhonchus and Sibilus, and large and small Crepitation; and I wish to see how far these will go in explanation of diseases of the lungs, before I proceed to consider others.

They belong to the mucous lining of the air passages, a structure, above all other structures which go to form the lungs, most obnoxious to disease; for it has been said, that, to whatever other structures disease may ultimately reach, it most frequently begins in this, and in whatever others it may begin, it almost always finds its way to this in the end.

I have called Rhonchus and Sibilus *dry sounds*, because I thought it particularly important to distinguish them from others which, arising from air and fluid in the act of mingling together, are properly denominated *moist* sounds. But I must warn you against inferring, from my designation of them as *dry* sounds, that a preternatural dryness of the air passages is essential to their production; for such is not the case. Indeed, respective to the conditions out of which they arise, I would rather say, of Rhonchus and Sibilus, that they were *not moist*, than that they were *dry*. And if you like it better, there is no objection to your speaking of sounds that *are moist* and sounds that are *not moist*, instead of sounds that are *moist* and sounds that are *dry*.

Rhonchus is the most fluctuating and inconstant of all sounds that belong to the lungs. It arises out of various pathological conditions, and out of some that do not deserve to be called pathological at all. It would be an affectation to pretend to speak of them all with precision.

People in perfect health are apt to have Rhonchus mixed with the ordinary respiratory murmur: they strive to clear their throat by a forced effort of expectoration, and sometimes bring up a little phlegm and sometimes not; they only displace it. Hereupon the Rhonchus ceases, and the respiratory murmur remains alone. Again, people suffering disease of the lungs are apt to have Rhonchus mixed with all sorts of unnatural sounds. They make an effort to dislodge or reject a little phlegm, and the Rhonchus disappears, but all the other unnatural sounds remain.

In these cases, the cause of the Rhonchus is evidently secreted matter from the surface of the bronchi: but why does it not produce crepitation, and not rhonchus?—simply because it is *not fluid* enough to allow the air to penetrate it, mingle with it, and pass through it. The air, in going in and coming out, passes by it and impinges against it, and suffers a vibration from it; and this yields the sound.

This Rhonchus, which is owing to tough and glutinous phlegm clinging to the part upon which it is deposited, is sometimes propagated over the whole, or a considerable part, of the chest: but then the extent of the Rhonchus is no just measure of the quantity of the phlegm. The phlegm may still be very small in quantity, but being lodged in the trachæa, or the first divisions of the bronchi, where they are very large and free, it vibrates, like a harp-string, to the impulse of air, and diffuses the Rhonchus far and wide through the chest.

But, whether this explanation be satisfactory or not, it is perpetually happening that a Rhonchus, heard in every part of the chest, is made to cease at once by a stout voluntary effort of expectoration. Indeed I may venture to say, from my own observation, that a Rhonchus may *almost always* be thus got rid of, whether it occur alone or be one amongst other unnatural sounds. And hence I infer that the cause of Rhonchus is *almost always* a small tough moveable piece of phlegm, adhering to the trachæa or first divisions of the bronchi.

The cause is, however, sometimes immoveable and permanent, and quite of another kind. Any thing, from within or from without, that has the effect of narrowing or obstructing a bronchial tube, in ever so small a space, may occasion the same sort of sound. Changes of structure within the parts themselves—such as a thickening of the mucous membrane, or the ossification of a cartilaginous ring; or morbid growths from without, such as a bronchocele, an aneurismal sac, or a tuberculous mass in the bronchial glands, or in the lungs themselves—have so compressed or distorted the trachæa, or certain bronchi, that the air could not force its way through them without continual vibrations, and without the respiration being constantly accompanied by a hoarse unnatural sound—by Rhonchus.

It is not easy to determine the conditions which are essential to the production of Sibilus. In seeking to assign them, I am left to my own reasonable calculation of what they *possibly may be*, having no direct means of proving what they actually are. I never knew any person die whose only auscultatory symptom was a Sibilus. Yet I believe people may and do die; and I have myself seen several in imminent peril of death, from disease of the lungs, whose only auscultatory symptom referable to the lungs has been a widely-diffused Sibilus. Of such cases I will speak presently: they are of great importance, and well deserve to be pointed out.

Sibilus, like Rhonchus, may occur alone, or in combination with other auscultatory signs. But whether alone or mixed with others, it cannot, like Rhonchus, be got rid of by an effort of expectoration. Yet the cause of both may be the same in kind, and different only in situation. A secreted matter, not fluid enough to admit air to mingle with its particles and thus produce a *moist* sound, but so consistent as to present a reverberating surface, and thus produce a *dry* sound, may be equally the occasion of Rhonchus and Sibilus. But in Rhonchus this matter is within reach of a voluntary succussion of the tracheæ and bronchi to expel it; in Sibilus it is beyond it. In Rhonchus it is contained within the first divisions of the bronchi; in Sibilus, within their lesser ramifications.

Sibilus, whether alone or in its combinations, cannot, like Rhonchus, ever be regarded as an innocent symptom. It is a more unquestionable evidence of disease than Rhonchus, in whatever that disease may consist.

Sibilus is almost always mixed with small Crepitation. They are united together in the same individual, and often succeed and supersede each other, as if they were contending together for the mastery; now one and now the other being predominant.

This mixture of Sibilus and Crepitation, and the predominance first of one and then of the other, are chiefly seen where both are largely diffused throughout the lungs: and in such cases one may often remark a fluctuation of the general symptoms answerable to this fluctuation of the auscultatory signs; that these symptoms, in their aggregate, become more inflammatory when the Sibilus increases, and less inflammatory when the Sibilus declines; also that the remedy which abates their general inflammatory character commonly abates the Sibilus; also when the expectoration is freer, the Sibilus is less, and when the expectoration is scanty, the Sibilus is more.

Now these are, indeed, great practical points, if they be true; and there are always examples enough to be found in this hospital by which you may test their truth. There are plenty of patients who have been suffering cough, expectoration, and dyspnœa, long and habitually,—some from disease which belongs primarily to the lungs—some from disease which is derived to the lungs from the heart. Watch these patients well for a few weeks together; mark the auscultatory signs and their fluctuations; mark the general symptoms and their fluctuations also; mark the treatment, and its adaptation to, and influence upon, both; and then judge whether the practical points, which respect the particular auscultatory sign now in question, are really such as I have represented them.

These cases of *chronic* bronchial affection are the most favourable for teaching the character of Sibilus, and how it stands related to other auscultatory signs, and to more general symptoms, and how it is amenable to methods of treatment. Such cases tell their story (if I may say so) more leisurely: they tell it over and over again, and with many interesting variations, and thus give you time to dwell upon it and understand it.

But still of Sibilus, that is thus mixed with crepitation, now superseding it, and now superseded by it—becoming less as the expectoration is more, and more as the expectoration is less—increasing as the general symptoms are more inflammatory, and yielding to the same remedies that they yield to;—of this Sibilus I do not pretend punctually to know the local efficient cause or exact pathological condition of the parts out of which it immediately arises. I am content to believe (without any curious speculation upon

things which I cannot prove) that, upon the access of a more inflammatory action, the secreted matter in many bronchial ramifications becomes more scanty and less fluid, so that the air that it breathed cannot freely mingle with it, and thus crepitation yields to Sibilus; and that, upon the subsidence of the inflammatory action, the secreted matter becomes more copious and more fluid, so that again the air freely mingles with it, and thus Sibilus in its turn yields to Crepitation.

But Sibilus does not occur under these circumstances only. It does not merely go and come, or occasionally intervene in chronic bronchial disease, of which the auscultatory symptom that is most characteristic and abiding is of another kind. There are cases in which Sibilus is itself the most characteristic auscultatory symptom,—cases in which for a long period, and cases in which even from first to last, there is no other auscultatory symptom whatever but Sibilus.

There are cases of (what I suppose would be called) genuine asthma, that present some such symptoms as these: dyspnœa, or rather an agony and fighting for breath; livid lips, cold and livid extremities, and a dry ineffectual cough, terminated and relieved, after an uncertain interval, by a copious puriform expectoration. Here, during the agony or paroxysm (and unfortunately it often continues long enough to allow a very leisurely examination of the chest by the ear—sometimes many days, sometimes a week or two) the sole auscultatory sign is a Sibilus pervading a larger or smaller portion of the lungs, according to the severity of the case. And as the agony lessens, and the expectoration begins to appear, Crepitation is found mingling itself with Sibilus; and, when the agony has *entirely* ceased, and the Crepitation become more copious and free, Crepitation, and Crepitation alone, is then heard in the same situations, and to the same extent, that Sibilus, and Sibilus alone, was heard before.

I have witnessed instances of asthma in several individuals, and several attacks of asthma in the same individual, where the auscultatory signs have had as strict and definite a correspondence with the stages, progress, and prominent symptoms of the disease, as that which I have here described.

Now, if absolute Dryness can be ever safely predicated of the respiratory passages, and can be ever safely reckoned among the pathological ingredients of their diseases, and ever clearly notified by one express symptom, it is in spasmodic asthma, of which it is the chief pathological ingredient during its first and often most protracted stage, and is clearly notified by a widely-diffused Sibilus.

I am persuaded that the natural moisture of the respiratory passages is *then* really in defect, and that Sibilus is really an index of the fact. Sibilus may then, if ever, be truly called a Dry sound. But I am not sure that the Sibilus directly results from the mere condition of Dryness; I doubt whether simple Dryness alone would naturally produce it. In consequence of its Dryness the mucous membrane may lose its elasticity, and become to a certain degree unyielding; or it may undergo wrinklings or puckerings at various spaces, or its general tumefaction may produce a narrowing of the smaller tubes, and thus present obstacles to the passage of air, and impart to it new vibrations; and hence the Sibilus.

Nevertheless, whether Dryness of the respiratory passages, or other conditions necessarily resulting from it, give immediate occasion to the Sibilus, the Sibilus may be properly regarded as the auscultatory symptom of the former. Dryness of the mucous membrane bespeaks a well-known pathological change; the other conditions are mere matters of conjecture.

Thus far I have spoken of Sibilus occurring in two forms of bronchial disease. 1st, As it intervenes among the auscultatory symptoms of certain chronic affections, characterized by dyspnœa, expectoration, and cough, instances of which are perpetually at hand to enable you to verify the fact. 2dly, As it presents itself as the sole auscultatory symptom that attends the paroxysm or agony of an asthmatic attack, when it is so marked that its presence can never be doubted. In both these forms of disease Sibilus conveys pathological and practical information of great importance.

But does Sibilus ever occur in acute bronchial or vesicular inflammation? And does it ever *so* occur as to throw essential light upon morbid processes going on, and essential light upon modes of treatment?

Inflammation of the bronchial ramifications perhaps never exists without the natural secretion of their mucous surface being either diminished or increased, and, consequently, without the accompaniment of those sounds which indicate its defect or excess; *i. e.* without Sibilus or Crepitation.

Sibilus is apt to occur at the beginning of such inflammation; and thus it corresponds with the pathological condition out of which it arises, the mucous membrane, when it is inflamed, becoming drier than ordinary before it yields a more abundant secretion.

Sibilus, too, after it has arisen, is apt to be of short duration, seldom abiding long as the *sole* auscultatory symptom of such inflammation. And herein also it corresponds with the pathological condition from which it proceeds; for the dryness of the mucous surface generally soon gives place to moisture.

Hence it happens that Sibilus is so seldom met with in practice, except with some mixture of Crepitation. The inflammation is, in truth, not submitted to our observation until the stage of *dry* sounds is passing, or has already passed, into the stage of *moist* sounds.

Nevertheless, there are cases in which Sibilus is the sole and abiding symptom derived from auscultation, and a Dryness of the air-passages the sole and abiding morbid condition for a considerable period. They are cases distinct from asthma, cases of genuine inflammation, and so remarkable as to require your especial notice.

I have met with a frightful affection in children; but what its nature was I could never tell, until auscultation enabled me to unravel it. It commonly passes for inflammation of the lungs. But when children have got well, they have got well so soon and so entirely, that I could never believe the disease to be pneumonia, although the symptoms seemed to indicate that it could be nothing else.

Last summer I went out of town to see a little boy, seven or eight years of age, whose life was very precious to his family. He was thought to be dying of inflammation of the lungs. I found him raised up in bed, supported by his nurse, and breathing with all his might. His skin was hot; his face flushed; and his chest heaved, and his nostrils quivered frightfully. There was no croupy sound. Whatever the disease was, it was all within the chest. I percussed the chest; it sounded well in every part. I listened: the air entered freely, and reached every cell and vesicle of the lungs; but there was not the least perception of the natural respiratory murmur; a shrill Sibilus had taken place of it altogether. Wherever you applied your ear to the chest, you might fancy you heard the piping and screaming of a nestful of unfledged birds.

But what was this disease? Surely it was inflammation largely diffused over the mucous surface throughout the bronchial ramifications, but inflammation as yet only in its *first* stage; for the air, as it passed through them, did not mingle with a particle of fluid any where, and the sound it produced was a dry Sibilus only.

But *how* inflammation yet only in its *first* stage? The boy had been already ill four days. Still it might be inflammation in its *first* stage. The boy continued ill two days longer, with the same kind and the same degree of suffering; and then, under the influence of tartar emetic, the fever began gradually to subside, and the dyspnœa to abate. The Sibilus gradually gave way to the healthy respiratory murmur, and he was well again *without expectoration of any kind.* The inflammation began and ended with the *first* stage; and although it continued with great severity for a week, it never got beyond the *first* stage.

This is an instance which strikingly shows the value of auscultation in detecting at once the state of things, about which you might go on conjecturing and conjecturing for ever what it *possibly* might be, and not gain the least assurance what it *actually* is.

In adults sometimes, but not so frequently as in children, I have met with the same evidences of acute inflammation widely diffused through the bronchial ramifications, and remaining in this its first stage for days and days together. In the meantime their mucous surface has still been dry throughout a great part of both lungs, and the ear has continued for days and days together to hear no other unnatural sound but a Sibilus. Convalescence has taken place without expectoration, and the sibilus has given way, without the intervention of any *moist* sound, at once to the murmur of health.

But such inflammation, after lingering long in the first stage, will sometimes pass beyond it; and the whole mucous surface that was previously dry will pour forth an enormous secretion, and the widely diffused Sibilus will be changed into a widely diffused Crepitation. Still the lungs are unhurt beyond the lining membrane of the air-passages, and the patient will get well, if he be not suffocated by the enormous expectoration.

I am speaking of a disease which must be distinguished from asthma, according to the usual acceptation—a disease not habitual to the individual, and of which, perhaps, he has never suffered a previous attack. I am speaking of acute inflammation extending throughout the bronchial ramifications, and reaching, perhaps, the vesicular structure of the lungs, putting on a peculiar form, and affecting a peculiar course; but still of acute inflammation, as further evidenced by the remedies necessary for its relief.

During the last summer I saw a gentleman, who had been, two days previously, seized rather suddenly with feverish symptoms, and with the most dreadful dyspnœa.

His lips were blue; he was labouring for breath, and coughing with hard and ineffectual efforts to rid himself of something which seemed to tease the larynx, but no expectoration followed.

Cupping on various parts of the chest (the state of vascular action required that blood should be drawn), and tartar emetic in frequent doses, were the remedies employed; but in the same state of agony he remained for a week, propped up in bed, striving with all his might to free himself from his oppression, coughing and endeavouring to expectorate, but ineffectually.

What was going on all this time? There was anguish enough for any disease of the most formidable name; for fluid in the pericardium; for extensive hydrothorax; for induration of a whole lung; for stricture at some orifice of the heart. A few years ago the most sagacious physician could only have guessed at the real state of disease, and probably would have guessed wrong. Such severe dyspnœa, so long continued, without expectoration, would probably have determined his diagnosis to hydrothorax.

But what was the disease? Every part of the chest sounded well to percussion. The heart beat regularly, and with a natural sound, only with too great frequency.

What could it be? There reached the ear from every part of the chest to which it was applied a loud Sibilus. The disease was an inflammation largely diffused through all (perhaps) of the bronchial passages, great and small—inflammation abiding long in its first stage, and limiting itself to one structure.

But in this case the inflammation ultimately passed beyond its first stage; for ultimately there arose an immense expectoration, and so the disease reached a favourable termination.

I have said that it is the peculiar praise of auscultation, not merely to discover disease in its ultimate results, but to analyse it in its several processes as it goes on; to mark its stay and continuance in one process, and its passage and transitus from one to another. Here we have a conspicuous instance of both these circumstances discovered to us by auscultation.

It is, I suspect, among the characteristics of inflammation, that in proportion as it is more widely diffused, it should be less rapid in its progress; not necessarily less severe, as far as severity is measured by force of vascular action and by fever, but less rapid in accomplishing its whole course; dwelling longer in each particular stage before it passes to another, than the inflammation which begins at a point.

Of this we have an example in acute rheumatism, which is diffused over similar structures in many joints simultaneously. In acute rheumatism, action and suffering are carried to the utmost degree of severity. There are extreme heat, and extreme pain, and extreme vascular action, in the parts, and in the constitution at large; yet all are expended upon one stage of inflammation.

Rheumatism may exist for weeks and months together, with all its pain, and heat, and vascular action, unabated; chronic in duration, but most acute in what respects action and suffering, it should seem that any length of time was permitted to it to do all that inflammation can effect within *a certain* limit, but that it was restrained by a strong, though not an invincible, law, from transgressing *that* limit, or doing harm beyond it.

After many weeks or months the inflammation will cease, and every joint be restored to the form, and feelings, and functions of health.

Such inflammation may exist in internal parts. (I do not mean rheumatic inflammation. Do not let me perplex you with a name: I only refer to rheumatism as to something well known, for comparison's sake, or analogy.) Inflammation, I say, may exist in internal parts, which (like rheumatic inflammation of the joints) is of a diffusive character, and occupies a large extent of surface at once, travelling tardily from structure to structure, slow to disorganize, abiding long in each of its stages, and giving leisure for the application of remedies in all of them. Such an inflammation is especially incident to the lungs; and, of the pulmonary structures, especially to the mucous membrane which lines the air-passages.

I have given instances of such inflammation of the bronchi lingering in *its first* stage, its stage of mere vascularity and defective secretion; and I have dwelt upon these instances for the sake of shewing you the real value of Sibilus as a pathognomonic sign. But for it, in the instances specified, I could not have made out the nature of the disease.

Of Sibilus I will venture to observe, that sufficient regard has not yet been bestowed upon what it is *in itself*. It is usually spoken of as conducting to Crepitations, and mixed with Crepitations, or moist sounds. But there wants some illustration of it in its separate import, as standing alone. To that illustration what I have said may perhaps contribute a little.

CLINICAL LECTURE

ON THE

REMOVAL OF THE SUPERIOR MAXILLARY, AND OTHER BONES OF THE FACE,

Delivered at the Westminster Hospital,

By Mr. Guthrie.

Mary Brown, aged 46, was admitted July 7, 1835, into this hospital, from Codicote, in Hertfordshire. She had long suffered from pain in the right cheek; but it was only in the autumn of 1834 that she felt an enlargement of the upper jaw, for which she had a tooth removed without relief, and afterwards another, without any essential benefit, the swelling continuing gradually to increase, and the pain, which was occasionally pricking, as well as lancinating and exceedingly severe, to augment. The tumor was firm and springy, and left no doubt as to its nature. It is unnecessary to give a further detail, as the case has been already reported by some gentleman about the hospital; and it is also of no consequence, further than that a little difference of opinion prevented my proceeding at first to the operation, and her health afterwards prevented its being done until my return from a tour I had made for the re-establishment of my own health in September.

I had made an opening into the tumor nearly opposite the foramen infra-orbitalis, from which a probe could be introduced into a cavity of some extent; and there was an opening where the teeth had been, which appeared to lead into the same cavity, and the discharge from which being swallowed, seemed to give rise to the derangement of stomach and diarrhœa by which she was so much troubled. Her health being, however, a little improved, I thought it right to defer the operation no longer, and many of you saw it done, exactly three weeks ago.

This operation is one of the improvements of modern surgery, within the last sixteen years, and for which we are principally indebted to our neighbours the French. The removal of a part, or parts, of the superior maxillary bone, has been had recourse to since the early ages of surgery, to which we need not refer. The removal of the whole, with its attachments, and even of the neighbouring bones, was, I believe, first attempted in France, but it is not settled by whom. Velpeau, in his "Médecine Opératoire," says that M. Paillard decides in favour of M. Dupuytren; M. Pillet for M. Gensoul. It has been done by Messrs. Stevens and Rogers in America, and Messrs. Lizars, Syme, Earle, Scott, Robert, and others, since that period, and their cases are reported; but the letter of M. Gensoul, of Lyons, in 1833, is the best monograph I have seen, and to which I have been much indebted in the course of my researches on this subject. But I believe so many of the bones of the face—as the superior maxillary, the malar, the lachrymal, the palate, and the inferior turbinated—were never removed at one operation before.

The antrum of Highmore, and the superior maxillary bone, are liable to many diseases I do not intend now to notice. There are, however, three in particular which require an operation, which may be mistaken one for the other, and lead, therefore, to error. The first is the malignant disease, or diseases, of the part; whether it arises from the membrane lining the antrum in the first instance, or from the bone, is indifferent. In the present instance the disease appears to have originated in the bone, which had been changed into a fibro-cartilaginous substace, which Mr. Kiernan, who has examined it, and is paying great attention to this subject, calls an albuminous sarcoma, the cavity of the antrum being more or less entire.

The second is when the disease appears to depend principally on an augmented growth of the bony paries, which, as in one of the cases related by M. Gensoul, had attained the thickness of an inch and a half. This is probably the result of inflammation of a common, not of a specific kind, and is cured by the removal of the anterior portion, which is a simple operation.

The third is when the tumor is caused by a sort of dropsy of the antrum, from whatever cause it may arise, which leads to its distention, and the gradual thinning and enlargement of its anterior wall. This is always curable by making an opening between the gum and the cheek, through the bone, by a chisel or strong pair of large scissars, through which the contents may be evacuated; after which the part gradually resumes its natural appearance. In such a case the tumor may be very large, and assume many of the characters of malignant disease; but it may be distinguished by its comparative incapability of resistance under pressure; the thin external wall of bone yielding and giving a crepitating sensation, which is highly characteristic of the complaint. In all cases, in fine, where doubt exists, the tumor should be punctured before any other operation is commenced.

Before I proceed to describe the manner of operating in the present instance, I will endeavour to make you understand the operation, so as to enable you to do it yourselves if a case should occur to you rendering it necessary; and I will draw your attention to the attachments first of the superior maxillary bone, and afterwards to those of the other bones it became necessary to remove. It is fixed in its situation towards the nose by its nasal process; within that it is attached to the os unguis, and to the os planum of the ethmoid bone, by the edge of its orbitar plate. The line of this attachment, if the edge of a chisel is placed on the edge of the orbit, is diagonally across the eye, from below and within, upwards and outwards.

On the outside it is attached firmly to the malar bone by its malar process, orbitary edge, and plate, as far back as the spheno-maxillary sinus; but as the os malæ must in general be more or less removed, its ascending orbitar process forming the outer edge of the orbit, and its zygomatic process, should be well considered. You will immediately perceive that these two parts are readily divided, and the orbitar plate of the malar bone easily yields, if the chisel or saw be carried on towards the spheno-maxillary sinus, through the medium of the foramen lacerum orbitale inferius. To do this the chisel must be held diagonally, in the opposite direction to that on the inner side of the bone.

The palate bone is firmly attached to the superior maxillary behind, the palatine plates of each forming one-half of the bony palate. Each plate is also firmly united to its fellow on the opposite side, and forms a point of attachment, which must also be divided by the chisel. The ascending portion of the palate bone being attached anteriorly to the superior maxillary bone, and posteriorly to the pterygoid processes of the sphenoid, form the fourth and remaining point of attachment; and the palate bone must be therefore either entirely removed, or be partly broken off, in which case the greater part of the ascending portion remains *in situ*, whilst the palatine plate is removed.

The internal maxillary artery is the only one of any importance which can readily be divided; and it, or any of its branches, which require a ligature, may be easily secured.

The second branch of the fifth pair of nerves is the only great trunk likely to be divided; and this may always be done by the knife, near the posterior edge of the orbitar plate of the superior maxillary bone, before it enters the infra-orbitary canal; by which means the injury likely to result from tearing the nerve will be avoided.

The plate before you shows the distribution of the pes anserinus of the seventh pair of nerves, some branches of which must be divided; but it does not follow that much or any deformity should ensue, as depending on that source of evil. The naso palatine and the inferior palatine branches, from Meckel's ganglion, must also be injured or divided.

The woman being seated a little inclining backwards, with her head supported by an assistant, I plunged the point of the knife down to the bone, a little below the insertion of the tendon of the orbicularis palpebrarum muscle, and carried it directly downwards by the side of the nose (leaving room for the passage of a ligature between the incision and the edge of the ala of the nose) through the lip, in as straight a line as possible. A second incision was then made outwards from the first, commencing on a line with the edge of the ala of the nose, until it reached nearly to the lobe of the ear; and from whence this terminated, another was carried upwards perpendicularly, to the side, and about one inch distant from the edge, of the orbit, and above its middle. The flap thus made formed three sides of a square, the fourth, or upper side, being the edge of the orbit. By the division of the lip and the second transverse cut, the lower part of the cheek could be turned down over the lower jaw; and Mr. Hancock will show you on the dissected head on the table, at your leisure, the situation of the duct of the parotid, which was in this manner avoided.

The next step was to separate the upper part of the tumor from the malar bone and edge of the orbit, and to insulate it from its attachments on its external edge; which done, I cut off the whole of that which formed the projecting part of the tumor, opening into what had been the cavity of the antrum, and showing that the disease occupied the whole of the bone, and rendered its removal necessary.

When a bone is inflamed, whether from common, specific, or inflammation of a malignant nature, it always becomes soft, the earthy particles being removed; a circumstance which greatly facilitates all operations on inflamed bone, and which was of great advantage on the present occasion. The malar bone being involved in the disease nearly as high as its attachment to the external angular process of the frontal bone, I divided it, with the help of the chisel and mallet, a little below that point, and then the zygomatic process. Another stroke of the chisel from the spot first divided, separated the

orbitar plate of the malar bone from the orbitar plate of the sphenoid bone, and passed under the eye into the foramen lacerum orbitale inferius, thus separating the malar bone. I now isolated the tumor on the orbitar plate of the maxillary bone, raising the eye, dividing the second branch of the fifth pair of nerves before it reached the infra-orbitary canal and the inferior oblique muscle.

The next step of the operation was to clear the line of the first incision, separate the ala of the nose from its attachments, open into the nasal fossa, cut through the mystachial suture, or rather a very little to the right of it, which was readily done by the chisel, which was then carried on in the palate through the palatine plates of the superior maxillary and palate bones. The chisel being now placed diagonally from within upwards and outwards across the ascending and nasal processes of the superior maxillary bone, and across the lachrymal sac, it was easily driven through; passing between the orbitar plate of the maxillary and the os planum of the ethmoid bone. If you examine the skulls before you, the line of junction of these bones will be immediately perceived. The chisel, guided by my two fore-fingers, was now carried as far back in the orbit, under the eye, as it could conveniently go, when all the loosened parts yielded under a little steady depression outwards, and the body of the tumor came away on the division of the soft palate, some attachments on the outer side of the tuberosity of the maxillary bone, leaving two processes, one of which was attached to the tonsil, the other above to the body of the sphenoid bone. There had hitherto been little or no bleeding, and at this time one artery sprung, of some size; but which ceased of itself, after filling the mouth twice or thrice, and causing a little delay. From the situation of the internal maxillary artery, which you may see injected in the head on the table, you will perceive that it must have been a branch that was divided—probably a pterygoid, rather than any other. In order to remove the process of tumor adhering to the tonsil, I seized it with a hook, drew it inwards, and dissected round it with some curved scalpels I had had made for shaving the cartilages of the ribs; one being round, the other sharp at the point. You will see on the dissected parts the vicinity of the internal carotid artery; and you may estimate the danger there was of cutting it, by any irregular motion of the patient or of mine. This part of the operation was, however, accomplished in safety. Another portion of the tumor was attached above to the body of the sphenoid bone, and the base of it could only be separated from the bone with great care, and with equal difficulty. It was the only point about which I had any anxiety; and I begged Mr. White and Mr. Thomson to say if they could perceive any the slightest portion remaining, and Mr. Keate and Mr. Stanley were so good as to do the same. These two last steps of the operation took up by far the largest part of the time occupied in its performance; and if any return of the disease should occur, it will be, I feel assured, from the last mentioned spot, and as no more of this could have been removed, unless a portion of the body of the sphenoid bone had been taken away, and which it would not have been safe to do, I regret that circumstances prevented this operation being done some months sooner: it would, I think, have been much more easily performed, and these two last attachments might not have taken place.

I allowed half an hour to pass away (having placed the woman on a bed) before I brought the external parts together; which was done by five hare-lip pins and as many sutures made of lead, and twisted instead of being tied. The hare-lip pins I removed on the fourth day, and the others on the subsequent one; leaving the whole of the incisions united. A small spot gave way on the eighth day, near the inner angle of the eye, where the skin was very thin, and another at the outer corner of the cross incision, about the size of a pin's head, and which last has nearly closed. The skin over the upper part of the tumor, forming the under eyelid, was so thin that I had great fears for its safety; it appears, however, likely to do well ultimately, although it is inflamed and irregular in its appearance. The upper eyelid has inflamed and swelled a good deal, but the eye is sound, and she can see very well with it when the lid is raised. M. Gensoul has observed that the half of the tongue of the affected side is covered by a crust, of a yellow colour, in these cases, whilst the opposite side, or half, is clean. I was not able to verify this statement, owing to her inability to open the mouth or protrude the tongue. The pulse was 126 before the operation, and the same after it. She has suffered much less pain than before, has slept on the whole well, has taken sufficient nourishment, and is, I believe, doing quite as well as can be desired.

Some eighteen months ago, an old officer applied to me for assistance, in consequence of a malignant tumor which appeared at the inner canthus of the eye, and which could also be seen in the

nostril. This I removed, but the disease returned, and he decided on submitting to a second operation, at which Mr. Keate, Mr. Partridge, and Mr. Hancock, assisted, at the Ophthalmic Hospital. I this time removed the eyeball, in order to enable me to clear the orbit, which I found I could not do without. The disease, after a longer interval, returned, and he is now, I am informed, dying in the country, blind of the other eye, deaf, and evidently suffering from the disease having affected the brain. If I had removed the whole, or even the upper part, of the superior maxillary bone, I think I should have done a great deal better, and might perhaps have taken away every portion of diseased structure. The eye was removed under circumstances not commonly met with, being quite sound. Mr. Partridge was so good as to take charge of it immediately on its removal; and, on cutting it across, to ascertain the state of the retina, I found that part quite transparent, as might have been expected. Our surprise was great, however, at not being able to perceive the yellow spot of Soemmering; and it was only after the lapse of ten minutes that it became at all observable. In a few minutes more it was very distinct, of a deep yellow brown colour, and the retina became gradually opaque. The lens and the circle around were also at first quite transparent, but the retina becoming opaque soon rendered these parts less clear. In a case of similar disease, occurring near the same time, but confined to the malar bone and its orbitar plate, I succeeded in curing the patient by taking it away, and by scraping even the periosteum, and the disease has not returned: but the periosteum cannot be scraped from the bottom of the orbit, unless there is a considerable space made to enable you to do it.

KIRBY'S BRIDGEWATER TREATISE.

STRICTURES ON THE CRITICISM IN THE MEDICO-CHIRURGICAL REVIEW.

To the Editor of the Medical Gazette.

SIR,

THAT the medical profession has often been accused of irreligion is too well known to be insisted on; and although prepared to maintain that, at the present day at least, the reflection is undeserved by the body against which it is directed, I must deeply regret that any thing should occur which might tend to countenance it. In the last number of the Medico-Chirurgical Review is a critique on the first volume of Mr. Kirby's Bridgewater Treatise, containing expressions which ought never to have been admitted into the pages of such a journal, occupying, as its editor does, a station which may give rise to the belief that the sentiments and language contained in the publication which is conducted by him are those which are standard, or at least current, in the profession of which he is a member.

The natural historian may reasonably maintain that the reverend author of the treatise has too literally rendered the prophecy of Isaiah, with respect to the harmony which shall some day prevail amongst the animal kingdom; but as the mode of subsistence not only of the first created animals, but also of those preserved during the Deluge, must be to a great extent a matter of conjecture, unless we admit the special interposition of Providence, it would have been well if the reviewer had allowed the author's supposition of a providential restraint on their instincts (supported as he is by the Mosaic record of—"to every beast of the earth, &c. have I given every green herb for meat") to have passed unnoticed, rather than have illustrated his position of the unnatural tenor of the idea, by the supposed conversion of a monkey into a man, or at least to have commented on it in language less repulsive to the feelings, and in a style of reasoning more analogically correct. Subjoined are the passages contained in pages 402 and 403 of the Review:—

"The author does not inform us at what precise period God altered the organization of the carnivorous animals, and adapted them to the digestion of vegetable food. No; he merely gives us his *ipse dixit* that God 'restrained their instincts,' and ordered the incisor teeth of the tiger to grind corn and rice, till such time as sufficient numbers of kids, lambs, and other animals, were multiplied to supply the altered gusto of the leopard, the lion, and the hyena!! Has the reverend author never reflected on the inferences which might be drawn from such doctrines as those which he has here promulgated? If animals can be thus changed in their nature, so far that the tiger may browse on the flowery lawn with the kid, why need we shudder at the idea of the monkey taking a start of growth at some remote period, and shooting up into a man?" &c. &c.

Whether Mr. Kirby has always correctly interpreted the manifestations of divine goodness and wisdom, is a consideration foreign to my purpose; for the admission

that he has not done so will afford no excuse for flippant observation, or levity of reasoning, on such serious subjects. I pass over the style of the reviewer's remarks on the coral reefs (*vide* Medico-Chirurgical Review, page 406), and those on the intestinal worms of man (page 412), with a simple expression of regret at their ever having been written; and I will direct attention to his comments on the reverend author's views of divine authority over all things; from which the reviewer complains, that the "evil principle in nature is excluded," "and all moral responsibility is taken away from man." Far better would it have been if he had construed the author in the sense which he intended (bordering as it is on the abstruse doctrines of predestination and prescience)—viz. that all things are under the superintending care of Providence. Better, likewise, if the following passages had been omitted:—

"If the Almighty guides the sword, and gives 'his commission to all his scourges, against individuals as well as against nations,' that being of whom we have heard so much, and whom we hate so heartily, has been most slanderously abused and belied! The office of Satan is a complete sinecure, and in these reforming days will doubtless be abolished. This doctrine is far worse than that of blind chance and fatalism. According to Mr. Kirby, it was the hand of the Almighty that fired the 25 muskets against Louis Philippe's cortège, and slaughtered the innocent and guilty indiscriminately! Where can be the justice of future rewards and punishments, if the sword, the dagger, the fire-damp, and the poison, were guided by Almighty, and consequently irresistible power?"—Med.-Chir. Rev. p. 412.

Your readers will scarcely believe that Mr. Kirby expressly guarded his writings against such a construction, or that the reviewer could have read the page which follows the one on which he made such comments. I subjoin it here, and leave your readers to form their own opinion on the justice of his interpretation of the author's meaning, the analogies by which he illustrates his conception of it, and the language in which he expresses himself.

"By what is here said, I by no means assert the doctrine of *inevitable fate;* for then there would be no use in the employment of means of prevention. *Sir H. Davy's safety lump would not preserve the life of the miner, nor Dr. Franklin's conductor disarm the thunder-cloud;* and all the other means that, *non sine Deo,* have been invented to render harmless the action of the physical powers under certain circumstances; but I would merely assert that constant superintendence of the Deity over the world that he has created, and *who upholdeth all things by the word of his power,* which we call Providence, by which in general, as well as individually, his will has full accomplishment; and every substance or being, whether animate or inanimate, takes the station which he has assigned to it. As God willeth not that any should perish, so he withholdeth not from any the means that, if duly used and improved, will be sufficient for his salvation; and in all his dealings with mankind he hath this great and merciful object in view*."

Dr. Johnson must be held morally responsible for the contents of his journal; and his station warrants the conclusion, that the Review conducted by him must be frequently considered as a criterion whereby to judge of the modes of thought and expression which prevail amongst the medical profession. The desire of preventing the odium of irreligion being affixed to our body, has induced me thus to extend my remarks, and to select the Medical Gazette for their diffusion. The reviewer may refer to one or two qualifying paragraphs which he has written, but your readers may judge how far they redeem his language, and justify his interpretations.

May I add, that in another part of this same number scriptural expressions are unnecessarily made use of? If, however, this letter shall remove the impression which the reviewer's comments are calculated to create,—not to say the stigma which they are likely to inflict,—if it shall prevent the repetition of similar expressions, and induce their author to reconsider his remarks, and repair the aggrievance which they must have occasioned to the feelings of an honourable divine, its writer's purpose will be fully answered.—I remain, sir,

Your obedient servant,
A Stranger to Mr. Kirby.

Oct. 31, 1835.

AN APOLOGY FOR GERMAN DIPLOMAS.

To the Editor of the Medical Gazette.

Sir,

Trusting to your impartiality and desire to act justly towards your professional brethren, you will perhaps permit me to make a few brief remarks on the subject of your well-written leading article of last week. The fact which you mention, respecting the diplomas obtained by some practitioners from the German Universities, cannot be denied; at the same time,

* Treatise, p. 362 3.

the facilities for procuring them are not quite so great as, perhaps, you have been led to believe: but that is not the point to which I would beg to draw your attention. It is well known to the profession that there are some few practitioners in this town, having the title of Doctor, who possess no other diploma than one from Germany or from Scotland, obtained from the latter before the recent regulations took place; and I think that some of the individuals alluded to are men of as high professional and moral character as their professional brethren generally. They are practitioners of many years' standing, and the cause of their being driven to the alternative of purchasing a foreign diploma is quite obvious; inasmuch as in this metropolis, where we have medical schools equal, if not superior, to any in the world, no man has an opportunity of obtaining a degree in medicine; consequently, if circumstances prevented his sojourning at a university in his youth, the doors to his obtaining high professional honours are closed against him; for I need not say, that should an established practitioner leave his practice for two years, to study at a university, he may as well abandon it altogether. Let a metropolitan university, with the power of granting degrees, be established, or let the power be delegated to any other public body, and I feel confident that you would hear no more about foreign diplomas.

I have the honour to remain, sir,
Your obedient servant,
M. D.

London, Nov. 15, 1835.

FUNCTIONS OF THE NERVES.

To the Editor of the Medical Gazette.

SIR,

IN Mr. Noble's interesting communication of last week, the condition of the *olfactory* function, in Davis's case, is not alluded to. By his being kind enough to state this, he would at once render the case more complete, and oblige

CARBONIC ACID GAS SOLIDIFIED.

THIS gas, which was some years ago reduced to a liquid form by Mr. Faraday, has been very recently rendered solid by a M. Thelorier, of Paris; and the fact vouched for by MM. Arago and Thenard, of the Academy of Sciences. It requires a temperature of nearly 100° below the freezing point of water, to solidify carbonic acid; but when reduced to this state, it is capable of remaining so, in the open air, for a few minutes. It does not expand violently, or explode, as the liquid does, but gradually disappears by a slow evaporation.

CHARLES HENRY ADAMS.

NOTICES.

With respect to the FARNHAM INQUEST, we are sorry we cannot respond to the appeal made to us. We published no report of the case; and the matter in question, we fear, would be as unintelligible, as it would certainly be uninteresting, to our readers.

The papers of Mr. Adams, Mr. Anderson, Mr. Armstrong, Mr. Bishop, Mr. Chatto, Mr. Davey, Mr. Alexander Shaw, Mr. Labatt, Dr. Clendinning, Dr. Farre, Mr. Niaarp, &c. have been received.

WILSON & SON, Printers, 57, Skinner-St. London.

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE X.

PACHYDERMATA.

WE have now arrived at the seventh order of mammals in the Cuvierian arrangement (for we obtain no remedial means from the sixth), which has been called *Pachydermata* (from παχυς, thick, and δεϱμα, skin), on account of the thickness of their hides. They are distinguished from all the preceding animals by the absence of claws or nails, and by the presence of one or more hoofs. They are totally incapable of grasping or seizing bodies by their extremities, which are only destined for the support of the body. The presence of hoofs, however, is not a character peculiar to them, being common also to that of ruminants. But the pachydermata may be readily distinguished from the latter order, by the greater simplicity of their stomachs, and the total absence of the power of ruminating or chewing the cud.

Cuvier makes three families of this order—namely,

Family the 1st, the *Pachydermata proboscidiana*, or those bearing a proboscis—as the elephant.

Family 2d, the *Pachydermata ordinaria*, or those devoid of a proboscis, but which have two, three, or four toes on each foot—as the hog.

Family 3d, the *Solipedes*, or *Solidungula*; those bearing no proboscis, and which have only one apparent toe and a single hoof to each foot, although, under the skin on each side of their metatarsus and metacarpus, there are spurs, representing two lateral toes. The horse and the ass are examples.

The two first of these families constitute the order *multungula* (or many-hoofed) of Illiger, Goldfuss, and others.

The second of these three families is the only one yielding any medicinal article, and that not an important one. I allude to the well-known hog's lard, which, being officinal, it is my duty to examine.

Sus Scrofa.

History.—The hog is an animal very anciently known. By the Levitical law, the Jews were forbidden to eat its flesh; some say on account of the filthy character of the animal, others because it was supposed to produce cutaneous and other diseases (more especially the leprosy), with which the Jews were much affected at the time they left Egypt. It is, perhaps, impossible now to ascertain to which of these two circumstances we ought to refer this prohibition, though the balance of evidence is considerably in favour of the first. The Mohammedans are also interdicted from eating it.

Etymology.—The generic name of the animal is from the Greek, συς: its specific name, *scrofa*, probably arises from *scrobs*, a ditch or slough, and refers to its dirty habits, " quod gaudeat *scrobes* facere."

Description.—The animal is so well known as to require but little description.

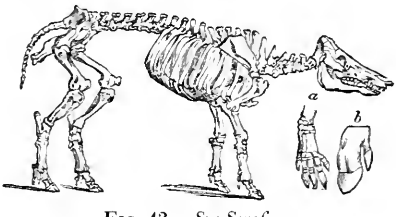

FIG. 43.—*Sus Scrofa.*

The teeth are from 42 to 44 in number—namely, 10 or 12 incisors; 4 triangular canines, long, and bent upwards and inwards; and 28 molars, the posterior ones having tuberculated crowns, while the anterior ones are more or less compressed. There are usually four (though sometimes five, fig. 43, *a*) toes, which are hoofed, the two middle ones only touching the ground. The snout is truncated, elongated, and cartilaginous; the body is covered with bristles; the colour is various.

Varieties.—There are an immense number of varieties of this animal; which, however, are most conveniently reduced to the three following:—

Variety 1.—*Sus scrofa ferus;* the *wild hog*, or *wild boar*.

Variety 2.—*Sus scrofa domestica*, the *domestic hog;* which again varies in regard to form and colour: compare, in this respect, the Chinese hog (fig. 44) with the Suffolk (fig. 45) and Herefordshire (fig. 46) breeds.

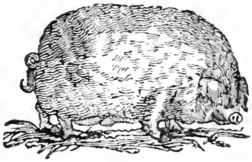

Fig. 44.

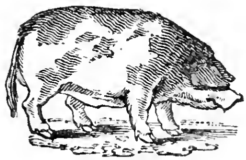

Fig. 45.

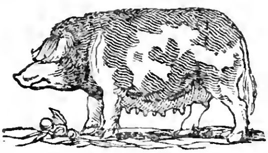

Fig. 46.

Variety 3.—*Sus scrofa pedibus monungulis*, that is, having solid or undivided hoofs; a variety noticed by Aristotle, Pliny, Linnæus, and others (fig. 43, *b*).

Geography.—It is a native of the temperate parts of Europe and Asia; of the northern parts of Africa, of America, of the Islands of the South Sea, &c. It was formerly a native of this country, and we are told that the forests on the north side of London were retreats for them.

Officinal parts.—As in other animals (man and the ox, for example), the fat about the loins has greater firmness and density than that of other parts, and is, therefore, preferred for medicinal use, and for domestic purposes, under the name of hog's lard (*adeps suillus; adeps porci*), or axunge (*axungia*) from the use anciently made of it—namely, greasing the axle of a wheel (*unguendi axem*).

Preparation.—In order to separate the lard from the membranous parts in which it is contained, the fat is melted over a slow fire, and then strained (through flannel or linen); and, in order to keep it, it is poured, in the melted state, into bladders. Sometimes salt is added, but this is highly objectionable for medical purposes. We may, however, readily remove it by melting in boiling water. When cooling, lard should be kept stirred, in order to prevent the separation of the stearine and elaine.

Properties.—At ordinary temperatures, it is a white or yellowish-white solid. Its melting point varies from 78° 5′ to 87° 5′. In the liquid form it should be perfectly clear and transparent, though when intermixed with water, it acquires a whitish or milky appearance. It should have very little or no taste and odour.

Composition.—Its ultimate constituents are carbon, hydrogen, and oxygen, with perhaps a minute portion of nitrogen.

	Chevreul.	Saussure.	Berard.
Carbon ..	79·098	78·843	60·5
Hydrogen	11·146	12·182	15·4
Oxygen ..	9·756	8·502	24·1
Nitrogen	0·0	0·473	0·0

But lard, like most other fatty bodies, is made up of three substances (called its proximate principles)—namely, one called *stearine* (from στεαρ, tallow, or suet), because it is solid at ordinary temperatures; a second termed *margarine* (from *margarita*, a pearl); and the third denominated *elaine*, or *olein* (from ελαιον, or *oleum*, oil), because it is liquid at common temperatures. Each of these requires to be noticed.

1. *Stearine.* — Here is some stearine, which I have obtained thus:—Lard, folded in blotting-paper and laid between two boards, was compressed in a vice, or press; by which means a considerable portion of the elaine was got rid of. The residue was dissolved in boiling alcohol; as the liquid cooled, the stearine deposited in a crystalline form. Or you may procure it by melting lard in sulphuric æther: when cold, compress the insoluble part (the stearine) first in a cloth, and then between folds of blotting-paper.

Stearine has the following properties: it is a white, easily pulverised solid; fusible at about 129°; soluble in boiling

alcohol, but separating by cooling; very soluble in boiling æther, but cold æther retains only $\frac{1}{225}$ of its weight in solution; saponifiable by alkalies, being converted by the assistance of water into stearic acid and glycerine (so called from γλυκυς, sweet, on account of its flavor). The following table shows the changes it undergoes in this process:—

Results of Saponification.

	Carbon.	Hydrogen.	Oxygen.		Carbon.	Hydrogen.	Oxygen.
1 Stearine	73	70	7	1 Anhydrous Stearic Acid	70	67	5
1 Water..	0	1	1	1 Glycerine	3	4	3
	73	71	8		73	71	8

All the figures refer to the number of atoms.

2. *Margarine* is solid at common temperatures; it fuses at 117° 5′ Far. Its solubility in alcohol is similar to that of stearine, but it is more soluble in cold æther; and hence it is obtained in the preparation of stearine, by allowing the ætherial solution to evaporate spontaneously after the stearine has been deposited. It saponifies by an alkali, producing glycerine and an acid. Query, is it margaric or stearic acid? Dr. Turner says it is stearic acid.

3. *Oleine*, or *elaine*, is distinguished from the stearine and margarine by liquidity at ordinary temperatures; its congealing point being, according to Chevreul, 44°. It is very soluble in cold æther and cold alcohol. Its specific gravity is 0·915. It is saponified by alkalies, probably producing glycerine and oleic acid, and perhaps also margaric acid.

	Stearine.	Oleine.	Stearic acid.	Margaric acid.	Oleic acid.
Carbon ..	78 02, or 73 atoms = 438	79·030	80·145, or 70 = 420	79·053, or 70 = 420	80·972, or 70 = 420
Hydrogen	12·2, or 70 atoms = 70	11·422	12.478, or 67 = 67	12·01, or 65 = 65	11·359, or 58 = 58
Oxygen..	9·78, or 7 atoms = 56	9·548	7·377, or 5 = 40	8·937, or 6 = 48	7·699, or 5 = 40
	100 564	100·000	100·00 527	100 533	518

The relative quantities of stearine, margarine, and oleine, in lard, have not been accurately ascertained. Braconnot obtained,

Stearine (but it was mixed with margarine)	38
Oleine	62
Lard	100

Now Dumas says that stearine constitutes about 25 per cent of lard; hence probably the relative proportions will be about the following:—

Stearine	25
Margarine	13
Oleine	62
Lard	100

Rancidity of Lard.—It is well known that when lard is exposed to the air for some time, it acquires an unpleasant odour, and is then said to be *rancid*. What is the nature and cause of this change? The first fact easily ascertained, is that rancid lard has become acid, since it reddens the tincture of litmus. This rancid condition is brought about by the agency of the air, part of the oxygen of which is absorbed, while a little carbonic acid is evolved. As stearine does not become rancid in the air, while elaine does, the rancidity of lard is referred to the latter. However, it has been found that the purer the elaine, the less easily does this process take place; so that it has been suspected there is some foreign substance in the elaine, which is the cause of the rancidity, either by undergoing decomposition or by acting on the elaine. Chevereul, whose elaborate experiments on fatty substances during ten years are so well known, analysed some rancid lard, and found in it the following substances:—

1. Unchanged stearine and elaine.
2. A volatile non-acid matter, having a rancid odour.
3. An acid analogous to caproic acid (an acid so called from *Capra*, a goat, because it is found in goat's milk).
4. Another volatile acid.

5. Oleic, margaric, and perhaps stearic acids.
6. An apple-yellow colouring matter.
7. A non-acid, non-volatile matter, soluble in water.

Physiological effects. — Like other fatty substances, the local action of lard is emollient, that is, it relaxes the tissues of parts. This effect has been by some compared to the power which all emollients possess of diminishing friction between the particles of inorganic bodies,—a comparison, however, which only holds good when applied to inorganized parts, as the nails, &c. By its sheathing properties it becomes a good demulcent. Its remote action is that of a nutrient.

The power of assimilation of fatty bodies varies considerably in different individuals, but, in most, a large quantity of fat cannot be easily digested. This is proved by the experience of persons whose digestive powers are weak, and by the experiments of Mr. Beaumont, an American surgeon, on a Canadian, who, in consequence of a gun-shot wound, had a permanent aperture in his stomach. From the experiments and observations on this man, one of the inferences drawn by Mr. Beaumont is, that "oily food is difficult of digestion, though it contains a large proportion of the nutrient principles." When digested, it appears, however, to be powerfully nutritive; and when mixed with other nutrient substances, its assimilation is promoted: and Dr. Cullen states the flesh of quadrupeds is nutritious in proportion to the quantity of oily matter it contains. Barbier says, that persons who take habitually much animal fat, are of a soft complexion, have lax muscular organs, and are subject to hernia and incontinence of urine. He assigns, also, as a reason, that some of the oleaginous particles, escaping the digestive process, get into the circulation, and thus exercise a local emollient action on the different tissues. But the whole account is, I believe, more imaginary than real. My observation does not bear out this statement, even in natives of this country. I have been acquainted with several persons who, although very fond of, and consuming large quantities of fatty substances, yet were not of a relaxed habit; and we all know that a great part of the animal food of a considerable portion of our hard-working country labourers is fat bacon; yet we see no symptoms in them of lax muscular organs. Most undoubtedly Barbier's assertion will not apply to the natives of the Arctic regions, who live in a great measure on fat and oil. It is certainly true that all persons do not possess the power of digesting much fat, but those that do I have for the most part found to be individuals of a strong constitution; and I am disposed to think, with Dr. Cullen, that when it can be digested, the more fatty the diet, the more nutritious. Sir John Ross considers that the natives of cold countries seem to require a more fatty diet than the inhabitants of tropical regions, in order to promote the production of animal heat. "All experience," says he, "has shown that the large use of oil and fat meats is the true secret of life in these frozen countries, and that the natives cannot subsist without it, becoming diseased and dying under a more meagre diet." And he goes on to say, "I have little doubt, indeed, that many of the unhappy men who have perished from wintering in these climates, and whose histories are well known, might have been saved if they had been aware of these facts, and had conformed, as is so generally prudent, to the usages and experience of the natives." I am acquainted with one instance that strikingly confirms Sir John Ross's views, namely, that more heat is generated in those who consume much fat. It is the case of a person exceedingly fond of fat, and who, although in the enjoyment of good health, has a remarkably hot skin, almost that of fever.

You may ask, in what respect does hog's-lard differ from other fatty bodies in its effects? It is a very old notion, that both the flesh and fat of the hog dispose to cutaneous diseases; but it is difficult either to prove or disprove this statement. As, however, it is undeniable that in some instances particular kinds of food do cause eruptions, thereby proving a close relation between the digestive and cutaneous system, I would advise you so far to conform to this notion, as to prohibit a diet of pork in all chronic diseases of the skin, by which you will be adopting the most prudent course.

The particles of fatty bodies are not easily absorbed, probably because they are not readily miscible with the blood, but the occasional detection of them in the secretions proves that they must have existed in that fluid.

Use.—In medicine we employ lard principally as a basis for various unguents; for example, mercurial ointment. It has been used as an emollient by friction; but this practice is rare. When employed instead of spermaceti ointment to dress blisters, I have frequently seen it excite considerable irritation.

RUMINANTIA.

We now come to the eighth order of Mammals, called *Ruminantia*, from the power which these animals possess of returning the food which they have already

swallowed into their mouth, to be remasticated at their leisure or while reposing. They are characterized by having incisor teeth (usually eight, but sometimes only six in number) in the lower jaw only; the two metatarsal or metacarpal bones are consolidated into one, called the *canon bone;* the feet are terminated by two fingers and two hoofs, which seem, by their flattened face, to have the appearance of one cloven hoof; and hence these animals have been called *cloven-footed*, or the *Bisulca*. But that which more particularly distinguishes them from all other animals, is the number and structure of their stomachs, and their faculty of ruminating. To these, therefore, I must in the first place direct your attention.

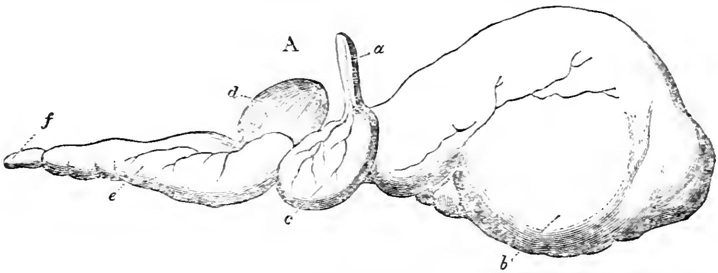

FIG. 47.

a, The gullet.
b, The paunch.
c, The honeycomb.
d, The manyplies.
e, The reed.

There are four stomachs—the paunch, the honeycomb, the manyplies, and the reed.

1. The first stomach, called *paunch, venter, rumen*, or *ingluvies*, receives the food

FIG. 48.

from the gullet after it has been roughly broken by the first mastication, and transmits it to the second stomach. It is often divided into pouches by transverse contractions, and is lined by a thick membrane, beset with numerous papillæ. (Fig. 48.) In this stomach the food undergoes little change, and it seems only to be kept here until the second is fit for its reception.

2. The second stomach, called *honeycomb, bonnet, king's hood*, or *reticulum*, receives the food from the paunch, rolls it up into balls, and projects it into the œsophagus, from whence it is transmitted into the mouth by the second mastication. The internal lining of this stomach is thrown into a number of folds, forming the sides of polygonal cells, (fig. 49) like

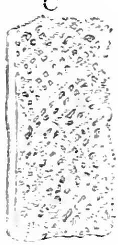

FIG. 49.

those of the honeycomb; and hence one of its names.

3. The third stomach, called the *manyplies, tripe, feck*, or *omasum*, receives the

FIG. 50.

food after it has been properly masticated. It also receives liquids direct from the œsophagus. This coat is remarkable for the number of longitudinal folds of its internal coat, and from which one of its names (manyplies) has been taken. (Fig. 50.) These folds have been compared to the leaves of a book; and hence the French call this stomach *Feuillet*.

4. The fourth stomach, called the *reed*, or *red*, or *abomasum*, receives the food from the manyplies. Here the gastric juice is secreted, and, therefore, here the process of digestion goes on. Its internal surface is irregularly folded. (Fig. 51.) An infusion of this stomach is used, under the name of rennet, to coagulate milk.

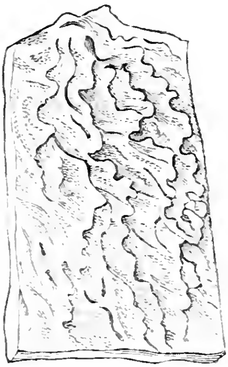

FIG. 51.

As the œsophagus is connected with three of these stomachs, you may ask how is it that the food passes into the paunch after the first mastication, but into the manyplies after the second? Some have supposed that it was effected by the voluntary act of the animal; but Flourens has explained it without reference to volition. He thinks it is the condition of the food, and the anatomical structure of the parts, which determines its passage into the first or into the third stomach.

The œsophagus opens at first almost equally into the paunch and honeycomb, and is continued afterwards, in the form of a gutter or semi-canal, into the upper part of the manyplies. Drinks and finely-divided semifluid food (as that which results from the second mastication) pass down the œsophagus and along this semi-canal into the manyplies, from thence to the reed. But when food is swallowed in large masses (as after the first mastication) it separates mechanically the edges of the semi-canal, and thus falls into the paunch.

Division of Ruminants.

We may arrange them thus:

1. *Ruminants without horns*, and having canine teeth in both jaws. This division includes two genera—*Camelus* and *Moschus*.

2. *Ruminants with horns* in the male animal. Of these we make subdivisions, thus:

(*a*). The horns caducous annually, branching: no canine teeth. Here we have the genus *Cervus*.

(*b*). The horns conical prominences, persistent, and covered with a velvety skin: the *Giraffe*.

(*c*). The horns hollow, persistent, elastic, growing by layers in osseous prominences: as the *Bos* or Ox.

For convenience, I shall commence with the ruminants with horns.

Cervus Elaphus.

History and etymology.—The genus Cervus has received its name, probably, from κερας, *horn*. It contains several species, which may be thus arranged:—

Cervus, or Deer	Horns entirely or partially flat ..	C. Alces, or Elk. C. Tarandus, or Rein Deer. C. Dama, or Fallow Deer.
	Horns rounded ..	C. Elaphus, or Red Deer. C. Canadensis. C. Virginianus. C. Axis.
	Horns small	C. Capreolus, or Roebuck. C. Pygargus. C. Muntjac. C. Porcinus. C. Mexicanus.

a, Cervus Elaphus. *b*, C. Capreolus. *c*, C. Dama.
FIG. 52.

The officinal animal, the C. Elaphus, has been known for a very long period. It is noticed by Hippocrates, Aristotle, Galen, Avicenna, and Pliny.

Description.—This animal has usually 34, though sometimes only 32 teeth; namely, 8 incisors in the lower jaw, two canines in the upper, but which are sometimes absent, and 24 molars. In the summer its colour is reddish-brown; in the winter greyish. The rump and tail are always of a pale yellow. The horns of the male animal (called the Stag) are, in fact, osseous prominences of the frontal bone, and are called *antlers*. They are long and much branched. These are the officinal parts, and I must therefore give you some account of their annual productions and shedding.

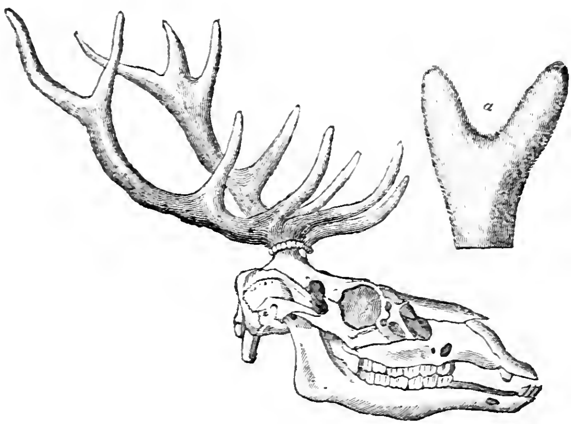

FIG. 53.

Growth and fall of the Antlers.—The stag usually begins to shed his antlers in February or March, immediately after which their reproduction begins, and by July he has completely renewed them. The first sensible phenomenon of the formation of these parts is the vascular excitement about the frontal bone. The arteries are observed to be enlarged, and to pulsate more strongly than usual; the heat is increased, and, in fact, all the symptoms of active inflammation come on. Very soon we perceive two cartilaginous tubercles, one on each side; these enlarge and elevate the skin, by which they acquire, from the distention of the latter, a velvety covering fig. 53, *a*) These tubercles are soon converted into real bone; but the deposit of ossific matter does not stop here; it continues around the base of the antlers, thus giving rise to what has usually been termed the *burr*. Now, consider for a moment the probable effect of this. These osseous prominences, the antlers,

are supplied with two sets of vessels—an external or cutaneous, which is the most efficient, and an internal. By the pressure made on the former by the burr, they are obliterated: the covering of the antlers no longer receiving a supply of blood, soon ceases to live, dries up, and falls off. The internal vessels continue to keep up the life of the bone for a few months longer, when death takes place. This occurrence may be in part owing to the imperfect nutrition, and partly, perhaps, to the exposure of the bone to the air without any envelope; but it arises principally from some unknown changes in the vital actions. The antlers being now dead, nature soon sets about their separation. To effect this, the living parts at the base are rapidly absorbed, so that the antlers, being left but very slightly adherent to the frontal bone, readily fall off by a gentle knock. A few hours only elapse before the irregularity on the surface of the os frontis is covered by a thin pellicle, and shortly afterwards the formation of a fresh pair of antlers is commenced.

Chemical properties.—*True horns*, such as those of the ox and sheep, consist principally of a substance analogous to *coagulated albumen* or *modified fibrine*; whereas the antlers of the stag (called *hartshorn*) have the same composition as bone; that is, they consist of an organized cartilage composed of *gelatine*, and, therefore, soluble in boiling water (more so than the cartilage of bones) and of *phosphate of lime*. The following are the proportions given by Merat Guillot:—

Soluble cartilage	270
Phosphate of lime	575
Carbonate of lime	10
Water (and loss)	145
	1000

The presence of the *gelatinous matter* is readily shown by boiling hartshorn shavings in water; and adding the infusion of galls. You observe there a copious precipitate (tannate of gelatine.) The *phosphate of lime* has the same composition as that found in bones, and therefore consists of—

3 Phosphoric acid	(72×3)	$= 216$
8 Lime	(28×8)	$= 224$
		440

so that it is, in fact, a subsalt. We readily obtain it by burning the antlers in a crucible, and thereby destroying all the organised or cartilaginous matter. But the *cornu ustum*, or *burnt hartshorn* of the shops, is usually bone ashes, the two being identical in composition. I have digested some hartshorn shavings in muriatic acid, and have thereby dissolved the phosphate of lime; you observe that on the addition of ammonia to the liquid, a white precipitate (of phosphate of lime) is thrown down.

Medical uses.—The decoction of hartshorn, like isinglass, is nutritive and emollient, and may be employed in intestinal or pulmonary irritation. Decoction of hartshorn is used by brewers, &c. for the purpose of fining. It is preferred to isinglass on account of its cheapness. The gelatinous matter of bones being less soluble than that of the antlers, shavings of bone will not answer so well as those of hartshorn.

The agency of the gelatine in this process will be readily comprehended. Some of the constituents of the liquor to be fined (the colouring matter, for example) coagulate the gelatine, which, in precipitating, envelopes within its parts the matters rendering the liquor turbid.

Hartshorn shavings are employed in the manufacture of antimonial powder.

Burnt hartshorn (that is, phosphate of lime) has been exhibited in those affections of the bones in which there is a deficiency of earthy matter, on the false notion that there was a want of this substance in the system; but the truth is, the deficiency of phosphate of lime in bones arises from an altered action of the vessels which ought to deposit this ossific matter, and not from a deficiency of material.

The liquor called *spirit of hartshorn* is in fact a solution of carbonate of ammonia in water, with a little empyreumatic oil. It is generally obtained by the distillation of bone, and hence it is called in commerce *bone spirit*; it will be described hereafter. The London College have superseded it by a solution of carbonate of ammonia.

I have now finished that family of ruminants having osseous and caducous horns, and proceed to notice another in which the horns are hollow, persistent, and elastic. First of the

Ovis Aries.

History.—The sheep is one of the anciently known animals, and is mentioned by Moses, Aristotle, and other old writers. The immense number of races of this animal in cultivation are well known; and it is now perhaps impossible to determine its native condition. Modern zoologists, however, refer our domesticated sheep either to the *ovis ammon*, called the *argali* of Siberia (fig. 54), or the *ovis musimon*, the *moufton* or *mufon* of Sardinia (fig. 55.)

FIG. 54.—*Ovis Ammon, or Argali.*

FIG. 55.—*Ovis Musimon.*

Description.—This animal has 32 teeth—namely, 8 incisors, and 24 molars. It is probable that in the natural state it always has horns; but a considerable number of the English breeds are hornless. When present they are hollow, thick, angular, wrinkled transversely, and curved spirally backwards and downwards, and are sometimes found in both sexes.

Varieties.—It is quite unnecessary for me to give any account of the almost innumerable races of sheep. You will find a good description, with figures of the British breeds, in Loudon's Encyclopædia of Agriculture. Here are representations of one or two varieties.

FIG. 56.—*Black-faced Sheep.*

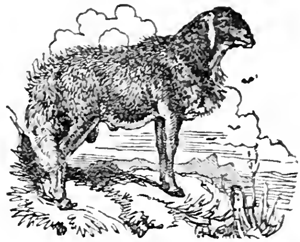

FIG. 57.—*Fat-rumped Sheep of Tartary.*

Officinal part.—The only officinal part of the animal is the fat about the kidneys and loins—the well-known mutton suet. It is prepared in the same manner as hog's lard.

Properties.—In many of its physical properties it agrees with lard. It has, however, a greater consistence, and fuses at about 98° or 100°.

Composition.—Its ultimate constituents are carbon, hydrogen, and oxygen.

	Chevreul.	Berard.
Carbon	78·996	65·0
Hydrogen	11·700	21·5
Oxygen	9·304	13·5
	100·000	100·0

It is composed of four proximate principles—namely stearine, margarine, oleine, and hircine. The three first have already been described under the head of lard.

Hircine is a fatty body, which has received its name from *hircus*, a male goat, because it has been found in the fat of this animal. Its properties, however, are very imperfectly known. It forms with oleine the liquid part of mutton suet. It is distinguished from oleine by its greater solubility in alcohol, by its goat-like odour, and by saponification yielding a volatile fatty acid, of an oily appearance, which, on account of its odour, has received the name of *hircic* acid. This acid forms with bases, salts called *hirciates.*

The relative quantities of stearine, margarine, and hircine, have not been ascertained.

The *effects* and *uses* of mutton suet are analogous to those of lard. In some cases it is preferred, on account of its greater consistence, as in the manufacture of certain plaisters and unguents. It is a constituent of the emplastrum cantharidis of the London Pharmacopœia, and of the unguentum sambuci of the Dublin.

I now proceed to notice the

Bos Taurus.

History and description.—Here is another animal very anciently known, and now so familiarized amongst us, as to require little or no description. It has no upper incisor nor canine teeth; the limbs are large and unwieldy; the forehead is longer than it is broad, and the horns are placed at the extremities of a prominent line, which divides the forehead from the occiput.

Geography.—It is found wild in Poland, the Carpathian Mountains, Lithuania, &c.

Parts used in medicine.—Although no part of the animal is officinal, yet I cannot pass it by without noticing one or two of its products useful to us in a therapeutical and dietetical point of view.

The milk is the first of these which I think it necessary to examine: it is secreted by two mammary glands which lie close together, and constitute the *udder.* Each gland consists of a number of *lobes*, made up of *yellowish* or *reddish soft granules.* These granules consist of very fine blood-vessels, nerves, and the commencement of the *milk* or *lactiferous ducts* (*ductus galactophori*, so called from γαλα, *milk*, and φέρω, *to bear*), which unite so as to form eight or ten principal ducts, which open into the large *duct* or *tube of the teat.* This tube is conical, and has a number of folds on its internal surface.

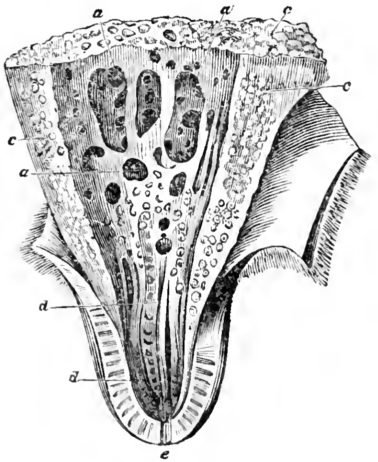

Fig. 58.

Many of the physical properties of milk are so well known, that it would be a waste of time to recapitulate them. Some of them, however, deserve notice. If you submit milk to examination by the microscope, you will observe that it consists of a number of *globular particles*, which float in a serous liquid. Raspail says they appear strongly coloured, and black on the edges, on account of their minuteness. They are not more than half the size of the globules of human blood; their diameters, therefore, will be about one-ten-thousandth of an inch. As I shall afterwards show, they are composed of a *fatty matter* (the well-known *butter*), and a coagulable substance of the nature of albumen, but which differs in some properties from the albumen of the egg, or of blood, and has been called *caseum*, or *caseous matter*, because it constitutes the basis of cheese.

These globules being specifically lighter than the liquor in which they are suspended, easily separate by standing. They therefore rise to the surface, carrying with them some caseum, and retaining some of the serum; thus forming what is called *cream.*

By agitation, as in the process called *churning*, the fatty globules unite into one mass (*butter*), leaving what is called *butter milk*, composed of caseum and serum.

The *skim milk* contains a considerable quantity of coagulable or *caseous matter;* but it is not quite clear that this is identical in its nature with that found in the cream. If an acid be added to skim milk, a white clot (called *curd*) is immediately formed by the coagulation of this caseous matter, while a thin liquid is left behind, called *whey.* To form this curd it is usual to employ the liquid called *rennet*, which is an infusion of the fourth stomach (*abomasum*) of the calf. Tiedemann and Gmelin have found in this stomach acetic and butyric acids, traces of acetate of ammonia, albumen, some other animal matter, besides acetate, phosphate, and muriate of soda and potash, and phosphate of lime. After all the curd has been formed by rennet, a fresh quantity of coagulum may be obtained by the addition of acetic acid. The substance which is thus coagulated has been by Schübler supposed to hold an intermediate place between caseum and albumen; and it has been called by the Germans *zieger*, by the French *serai.* Berzelius, however, thinks it is merely a combination of the uncoagulated caseum with acetic acid.

The *whey* which is left by the separation of the curd and serai yields on evaporation *sugar of milk*, one or more *azotized substances*, the nature of which is not well known (*osmazome ?*), *lactic acid*, and some *salts.*

The following table shews the composition of milk, and of some of the products used in domestic economy (as cream, &c.): —

- MILK
  - Cream ....
    - Butter ....
      - Fatty Matter solid at ordinary temperatures .. *Stearine.*
      - Liquid Fatty Matter....
        - By saponification yielding Butyric, Caproic, Capric, Margaric, and Oleic Acids, and Glycerine .... *Butyrine.*
        - By saponification yielding no Butyric, Caproic, nor Capric Acids .... *Oleine.*
    - Butter-milk ....
      - Caseum.
      - Serum.
  - Skim-milk
    - Matters which are coagulable
      - by Rennet .... *Caseum*, or *Curd.*
      - not by Rennet, but by Acetic Acid.................... *Zieger*, or *Serai.*
    - Serum, or Whey ....
      - .... *Sugar of Milk.*
      - Azotised Matter .... *Osmazome?*
      - .... *Lactic Acid.*
      - Salts ..
        - Soluble in Alcohol
          - *Lactates* of Potash (principally), Soda, Ammonia, Lime, and Magnesia.
          - *Chlorides* of Potassium and Sodium.
        - Soluble in Water, not in Alcohol
          - *Sulphate* of Potash.
          - *Phosphate* of Potash and Soda.
        - Insoluble in Water
          - *Phosphates* of Lime, Magnesia and Iron.

In this table I have taken no notice of the existence of a little butter in butter-milk and skim-milk.

We cannot help being struck with the remarkable analogy which exists between milk and an emulsion (as that made with almonds.) Both have a whitish appearance and a sweetish taste; both, on examination by the microscope, are found to contain an immense number of oily globules, held in suspension by an albuminous matter and sugar; and both are intended for the nourishment of young living beings.

Of the constituents of milk there are only about three which require a separate notice. I shall first examine *caseum*, or the *coagulable matter of milk*, including under this head *zieger*, or *serai*, which I cannot regard as being essentially different from caseum. Caseum must, I think, be considered as agreeing in many of its properties with liquid albumen, from which, however, it is distinguished by its non-coagulability by the agency of heat, and by the products of its spontaneous decomposition. It is, however, easily coagulated by acids, as I have already mentioned. In all probability the coagulated caseum is a compound of the acid and caseum.

In the manufacture of cheese (of which caseum is the base) rennet is commonly employed to coagulate the caseous matter; but I understand that in the manufacture of Dutch cheese, muriatic acid is employed; to which, we are told, its pungency and freedom from mites are to be referred. Various salts also coagulate caseum: I shall only shew you examples of a few of these—namely, perchloride of tin, sulphate of copper, nitrate of silver, and perchloride of quicksilver (corrosive sublimate). [The experiments were shown.] What may be the exact nature of the change in these cases I will not pretend to offer an opinion, further than that in all probability the caseum combines both with the acid and the basic constituents of the salt employed. Putting theory aside, these facts and experiments are of considerable practical importance. The salts employed lose, by their combination with, or alteration by, the caseum, a great part of their activity; so that milk (as containing caseum) becomes a valuable agent to us in the treatment of poisoning.

I have already mentioned that the products of the spontaneous decomposition of caseum distinguish it from albumen; but they connect it with the gluten of vegetables, which undergoes a series of analogous changes by exposure to the air in the moist state, constituting a remarkable kind of fermentation. Braconnot, who is the latest experimenter on this subject, says that *curd* (obtained from spontaneously coagulated skim-milk), covered with water, completely putrified in the space of a month; and that he obtained two classes of results: the one *soluble* in water, having an unpleasant odour, and containing *free acetic acid*, much *acetate of ammonia*, a little *acetate* and *muriate of pot-*

ash, *ammoniacal phosphate of soda*, a yellow acrid *oil* (the cause of the pungent taste of old cheese), resin, *caseous oxide* (called by Braconnot *aposépédine*, from απο, *from*, and σηπεδων, *putrefaction*, because it is a product of putrefaction), *two substances* analogous to osmazome, and *phosphate of lime*. The other class of results obtained by Braconnot was *insoluble* in water, and contained a *brown animal matter*, *margarate of lime* (the base of which came from the lime in the caseum), and *margaric* and *oleic acids*.

Butter is another constituent of milk deserving a short examination. Its physical characters are known to all of you. It is composed of three fatty bodies, one a solid (stearine), and two liquids—viz. oleine and *butyrine*; the characteristic distinction of the latter being, that by saponification it yields butyric, caproic, and capric acids, all of which are volatile and odoriferous, and therefore readily distinguished from stearic, margaric, or oleic acids, which are fixed. If to a solution of a soap made with potash and butter we add tartaric acid, and distil, the volatile acids pass over; the fixed ones remain behind. This distilled liquid, therefore, will contain butyric, caproic, and capric acids.

Sugar of milk is obtained by the evaporation of whey. That which is met with in commerce is made in Switzerland, from the whey left behind in the manufacture of cheese. The specimens which are before you were received from Paris. They occur in cylindrical masses, in the middle of which you observe the stick or thread which serves as a nucleus for the crystals. This kind of sugar differs from common sugar in several peculiarities, the most marked of which are the following:—It is incapable of undergoing the vinous fermentation (a vinous liquor called *koumiss* is, however, made from mare's milk by the Tartars)—is very slightly soluble in alcohol—is less soluble in water than common sugar, and by the action of nitric acid yields, amongst other products, saccholactic or mucic acid; so that this kind of sugar forms, as it were, a connecting link between common sugar and gum; and, like starch, it is converted into common sugar by boiling in very dilute sulphuric acid. Berzelius states its composition to be—

5 Carbon	30
4 Hydrogen	4
4 Oxygen	24
Atomic weight,	58

If this statement be correct, its composition differs from common sugar.

Lactic acid is a substance highly interesting in a chemical point of view, but is of secondary importance in reference to pharmacology. Gmelin contends that the so called lactic acid is merely a compound of acetic acid and animal matter; but the opinion seems disproved by the elaborate experiments of Berzelius. The *nanceic acid* of Braconnot, or the *zumic acid* of Thomson, is merely a mixture of lactic and acetic acids.

Physiological effects of milk.—I need hardly tell you that milk is a powerfully nutritive substance, since we all know it is the principal or only aliment of mammals during the first periods of their existence. The essentially nutritive parts are the butter, the caseum, and the sugar. But we must not pass over the phosphate of lime and lactic acid. The bones of young animals are imperfectly formed; they consist principally of cartilage, and contain a less quantity of phosphate of lime than is found in the bones of an adult. It is evident, therefore, that at this period of life phosphate of lime, or its constituents, is an essential substance for the perfect development of these beings. Nature, ever provident, and careful not to give wants without accompanying them with the means of satisfaction, has placed phosphate of lime in the milk. But it will be immediately said, how is it held in solution? In all probability by lactic acid; for this substance has been found to dissolve it readily out of the body, and therefore we see one use, at least, which this peculiar acid has in the milk.

The quantity of nutritive matter in milk varies, not only with the species of animal from which the milk has been obtained, but even in the same species—nay, in the same individual under different circumstances.

The following table has been drawn up from the best analyses of milk which have been published:—

100 Parts of the Milk of the	Cream.	Butter, or Fatty Matter.	Caseum.	Sugar of Milk.	Total Butter, Caseum, and Sugar of Milk.
Ewe (Stiprian Luiscius, and Bondt)	11·5	5·8	15·3	4·2	25·3
Goat (ditto)	7 5	4·56	9·12	4·38	18·06
—— (Payen)	(not stated)	4·08	4·52 including insoluble salts.	5·86 including soluble salts.	14·46
Cow (Stiprian Luiscius, and Bondt)	4·6	2 68	8 95	3·60	15·23
—— (Berzelius)	(not stated)	4·5	6·10	3·5	14·10
Woman (Payen) 1st case	(not stated)	5·16	0·180	7·62	12·96
Woman (Payen) 2d case	(not stated)	5·2	0·250	7·930	13 38
Woman (Payen) 3d case	(not stated)	5·18	0 240	7 86	13·28
Ass (Stiprian Luiscius, and Bondt)	2·9	..	2·3	4·5	6·8
Mare (ditto)	0·8	..	1·62	8·75 only 3 7 according to Young.	10·37

By reference to the fifth column of this table, you will see what very unequal quantities of nutritive matter these different kinds of milk contain. However, the discrepancies among authors is so great on this subject, that I have no great faith in the correctness of the above table, though I have drawn it up from the best data we possess.

The milk of the same species is also liable to considerable variation, depending on numerous causes; for example, the quality of the food modifies the quality of the milk. Dr. Young found that a bitch fed on vegetable aliment yielded an acescent and spontaneously coagulable milk; but when animal food was employed, the milk was alkaline, and did not spontaneously coagulate.

Dr. Cullen says, "I allege it to be a matter of experience, that supposing the quantity of liquid to be the same, nurses living entirely, or for the greater part, upon vegetable aliment, afford a greater quantity of milk, and of a more proper quality, than nurses living upon much animal food. This I venture to assert, from the observations of fifty years."

The influence which many medicines taken by the mother have over the suckling infant, is a circumstance known to every nurse, though Cullen denies it. We can modify the *colour* of the milk by mixing saffron or madder with the food; the *odour* may be affected by various cruciferous and alliaceous plants; the *taste* may be altered by the use of bitters, as wormwood; and lastly, the *medicinal effect* may also be influenced. Children may be salivated by suckling nurses under the influence of mercury, or purged by the exhibition of drastics to the nurse. Mental emotions also affect the quality of the milk. I have frequently seen the bowels of the child disordered in consequence of some sudden mental emotion on the part of the mother. It is also not improbable that diseased conditions of the parent may render the milk unhealthy. Labillardiere states that the milk of a cow, affected with a kind of tuberculous phthisis (*pommelière*) contained seven times more phosphate of lime than usual. Now this is a circumstance of the greatest moment, not only in reference to the frequency of this affection in cows, and, therefore, to the possible morbific character of such milk, but it is of considerable importance in reference to the milk of the human subject. I think, with this statement before us, it is highly improper to allow a female with any trace or suspicion of tuberculous disease to suckle. Not that a few grains, more or less, of phosphate of lime in the milk can probably do any injury to the child, but the fact once established, that the milk may be thus altered by disease, leads to the suspicion that some other substances not yet recognised by their physical or chemical characters, may be in the milk of diseased nurses, and which may have an injurious influence on the child; and the suspicion

does not confine itself to those affected with tuberculous diseases: other hereditary or constitutional affections may also be attended with altered conditions of the milk. This suspicion is strengthened by the common observation that the milk of nurses will not equally suit children. A child quite healthy, and in good condition, will sometimes, without any evident disease, fall off, and get into what is commonly called a bad condition, apparently from a change of the nurse. I am aware that we cannot always refer this to any positively hurtful matter in the milk. The quantity of nutritive matter in the same quantity of milk of two nurses, may be very different: according to Payen, milk with too much nutritive matter in it may disagree with the child. Another point worthy of attention, is the quantity of milk yielded in a given time. Payen says it varies in different women as much as from 1 to 10½. Climate, age, and period after delivery, are among the circumstances influencing the quantity of milk secreted.

Medicinal uses of milk.—We take advantage of the nutritive qualities of milk either as an article of diet, or as a ready means of introducing a large quantity of nourishment into the system in a short period of time. For example, after violent hæmorrhages, as those from the uterus, milk is one of the best nutrients we can employ. In these cases the most nutritive milk (as that of the goat, ewe, or cow) will be the best. A milk diet has been strongly recommended in consumptive cases, and sometimes with benefit. It has also been recommended in gout. Probably we ought to regard it as a negative means—that is, it is nutritive without being exciting. In these cases, woman's or ass's milk is the best.

We employ milk also as a demulcent. Thus it is used in the form of lotion or cataplasm, mixed with crumb of bread: it quickly undergoes decomposition, and then acts as an acrid substance. Internally, milk is an exceedingly useful demulcent in irritation, or chronic disease of the digestive organs. In poisoning by all acrid poisons it is useful, and in some cases acts as an antidote—as in poisoning by corrosive sublimate, perchloride of tin, sulphate of copper, &c.

The whey of milk is a mild refrigerant; but when taken warm with a stimulant (as wine), is a powerful diaphoretic.

Gelatine is another product from the ox which has been used in medicine. It is obtained by boiling bones in water. In Paris a nutritious soup is prepared, for hospitals and other pauper habitations, from bones; which are first digested in hydrochloric acid, to dissolve out the phosphate of lime, and then boiled in water. Soup has even been prepared from the fossil bones of the great mastodon, by a Prefet of one of the departments of France. Seguin employed gelatine as a tonic in agues. He thought that the active principle of cinchona bark was gelatine, since it precipitated the infusion of galls like the latter substance.

An extract of *ox bile* was formerly employed in medicine as a tonic, in doses of a few grains in the form of pills. This extract consists (according to Berzelius) of

Biliary matter (considered by Thenard and Gmelin as a compound of several proximate principles).
Mucus of the gall-bladder.
Alimentary extract.
Muriate and lactate of soda.
Soda.
Phosphate soda, and lime.

REPORT OF THE DISEASES OF MARYLEBONE,

AS OBSERVED IN THE PRACTICE OF THE ST. MARYLEBONE INFIRMARY,

From July 24, 1835, to November 13, following.

TABLE *of Admissions, Discharges, and Deaths, from July 24th, to November 13th,* 1835.

	In Patients.	Out Patients.
Under treatment on the 24th July, 1835	169	50
Admitted to 13th November	572	724
	741	774
Discharges from 24th July to 13th November	430	602
Deaths	91	48
Out-Patients admitted into Infirmary	—	80
Under treatment on 13th Nov.	220	44
	741	774

Observations on the Table of Cases.

From July 24th to September 9th, the decline of seasons appears to have had little effect on the health of the poor of the district of Marylebone. The admissions into the Infirmary during that period varied little. From July 24th to 31st, thirty-four persons were admitted as in-door patients, and fifty-one as out-door. At the middle of the period, viz. Sept. 25th, the admissions were—in-patients, thirty-six; out-patients, thirty-nine; but within a few weeks after, an increase became sensible. At the close—namely, Nov. 13th, the admissions of the preceding week were—in-patients, forty-nine, out-patients, fifty-two.

With respect to the cases of ophthalmia, psora, and porrigo, an observation formerly made may here, without impropriety, be repeated. From the columns of in-patients, compared with those of out-patients, there appears a singular preponderance for an hospital of such cases which are as well or better suited to the resources of a dispensary. The reason is, that all cases occurring amongst the hundreds of children in the Workhouse Schools, have instant admission into the Infirmary.

Grand total for Infirmary and Workhouse	112	

Observations on the Table of Deaths.

From even a cursory glance at the above table of deaths, it will be observed that the mortality is considerable when compared with that of some other hospitals. One principal reason of the mortality will appear from the following table, containing the ages of the dead, given in periods of ten years:—

	Males.	Females.
To age of 10 inclusive	5	10
.. 20 ..	1	2
.. 30 ..	4	8
.. 40 ..	6	10
.. 50 ..	7	8
.. 60 ..	6	2
.. 70 ..	6	10
.. 80 ..	6	11
.. 90 ..	2	5
.. 100 ..	0	1
	43	67 = 110

In the British Medical Almanack, the editor of which seems much versed in statistical inquiry in general, also to have taken considerable trouble in collecting information respecting London hospitals, the mortalities of eight

principal hospitals are stated [B. M. A. 1836, p. 122] to vary from 7·6 per cent. (Bartholomew's) to 10·6 (St. George's) on the totals of admitted in-patients. From private information I can depend on, I am inclined to think that statement substantially or in the main correct. Yet those hospitals are authorized to refuse, and often do refuse, admission to hopeless cases, especially phthisis; to all infants, &c.

From the preceding table, it appears that more than one-third had passed 60 years of age, and considerably more than one-eighth were young children—several, in fact, infants. Another reason, also, is prominent in the table—namely, the large proportion of diseases of the organic kind, admitting of palliation only, and ultimately fatal, under whatsoever treatment or circumstances. Phthisis, and disease of the heart alone, give 42 of the 112.

I have instituted some inquiries respecting the mortalities of other parochial charities, and from such answers as I have already been favoured with, I consider the St. Marylebone mortality rather below than above the average of such institutions; as most assuredly, from its airy site and superior internal arrangements and resources, I should have expected. In an adjoining parish, to give an example, which has a large workhouse and well ordered sick wards, and good professional attendance, I learn, from a statement in my possession, that, from July 24, 1835, to November 13th, the mortality was to the admissions, including those under cure July 24th, as one to five; one-half nearly, or about one-sixth (to use a round number), greater than the St. Marylebone mortality.

The mortality table includes three deaths from old age; but of the 112 deaths it records, 21 occurred in the Workhouse, in which, independently of the sick-house, the old name for the Infirmary, there are wards for lying-in women, for idiots and epileptics, and for infirm and bed-ridden persons; altogether fourteen wards, which are under the charge of the resident assistant surgeon-apothecaries, superintended in the accouchement department by my distinguished friend Dr. Robert Lee.

Cholera.—The cases of cholera noted in the table of deaths, occurred all in August and September, and were the only cases fatal in a total of 16.

Owing to my absence in Dublin during the meeting of the British Association, and elsewhere on business afterwards, the whole of the cases, with one exception, were under the care of my able colleague and friend, Dr. Sims, so that I cannot speak of them from personal observation: they were of all ages, and, as the table shows, of both sexes—five were under 20 years of age, seven were above 60. In more than half, the characteristic symptoms—viz. rice-water evacuations, vox cholerica, ghastly expression, cramps, blueness, coldness, and attenuated and nearly insensible pulse—were present on their introduction into the Infirmary. In the others, the coldness and lividity, cramps, &c. were less intense, and the pulse could always be easily counted; but in a general aspect, they agreed with the former, and were no doubt of the same family. The practice was in nearly all the same, viz. calomel and opium at short intervals, with effervescing draught, for the first day and night, followed on the second day by mild aperients. The hot air bath also was used, nothwithstanding strong aversion to the heat, and to the fixed position it required in several instances, and with apparently very good effect. The most striking advantages arising from it were suppression of the cramps, and a return of warmth to the chilled extremities. The use of calomel and opium was generally followed by bile in the stools on the second day of treatment, and by immediate or speedy relief, to a greater or less extent, of gastric irritation.

One body was examined, and presented the usual choleric appearances, viz. parenchymatous congestion in every cavity, pasty coating of the mucous membrane of the small intestines, gruel, rice-water, &c. in the cavities of the latter, and black coloration of the tissue of the former; the heart charged with black blood.

In one case, I understand, in which there were symptoms of cerebral oppression, bleeding to 8 oz. was used, and with much advantage.

Aneurism of the Aorta.—The lamented death of Sir David Barry, occasioned by rupture of an aneurism of the aorta, has given a transitory additional interest to cases of that class. There have been several instances of the disease very lately in the Infirmary, the remains of some of which have been inspected. The most nearly resembling that of Sir D. B. was that of

a female, of 65, who died suddenly on the 10th ult. She was of short stature and plethoric habit, and was an inmate of the Workhouse until just before her death. It was not suspected that any disease of that kind had existed. Shortly before her admission, she had had some uneasy sensations, for which she had recourse to smoking, but was speedily seized with faintness and syncope, and soon died. Next day her remains were examined, when the heart was found floating in blood, of which probably half a pint at least was poured out from the sac of the pericardium after a free incision; there was aneurism of the aorta ascendens, from the cavity of which the blood had escaped through an elongated irregularly-shaped opening in the wall of the artery into the cavity of the pericardium.

Aneurism and Hypertrophy. — Two days after, we inspected the remains of a patient of mine, a man of 48, long ill of hypertrophy of the left side of the heart. In the summer of 1833, he had undertaken a pedestrian contest with another man to Brighton, for a wager. In something more than eleven hours, he stated that he had completed his journey less by two miles, when he felt himself unwell, shortly became faint, sat down on the road-side, and of course lost his wager; ever since he has been suffering from heart-beat and other symptoms referable to organic lesion, and on the 13th of October was admitted under my care. Nothing availed to give him permanent relief, and in a month he sank. During his stay in the Infirmary, the bellows sound was always very conspicuous in front, and sometimes behind and at the side; the first, or ventricular sound of the heart, was well marked, but the second, or short sound, was missing, obscured, apparently, by the *bruit de soufflet.* The inference was, in addition to hypertrophy of the left ventricle, defective action of the systemic semilunar valves. We found, accordingly, in addition to hypertrophy of the systemic ventricle, whose walls were thick and massive, and cavity probably double the normal size, considerable deficiency of the valves of the aorta: one was puckered, and a second was attenuated and curved outwards, so that the free edge must have extended beyond the line of traction, and yielded to some extent to every impulse from either side. But the principal source of defective valvular action seemed to be the expansion of the cavities each side of the valves: for, in consequence of the aneurisms of the heart and aorta, the communicating opening was itself expanded, the valves removed from each other, and free influx secured to a large portion of the aortic contents. The aorta was, through the greater part of its length, expanded, and every where more or less charged with atheromatous deposit. In the abdomen, at the root of the cœliac axis, was found a small aneurismal sac, which, had the patient not been cut off by one of the syncopes to which such subjects are liable, must ere long have destroyed him. In such a state of permanent patency to a greater extent of the outlet of the left ventricle, it is obvious that the signs of defective valvular action must be well marked, whether we suppose, with perhaps a majority of pathologists of this country, that the bellows sound depends simply on reflux, or that it is caused by divergency or eddies in the refluent current, as maintained by Dr. Corrigan, in an able address to the medical section, at the late meeting of the British Scientific Association.

Poisoning with Sulphuric Acid. — The case marked in the table "Poisoning," was that of a woman of 28, who, from some disappointment in love, swallowed $1\frac{1}{2}$ oz. of sulphuric acid, and was immediately seized with the symptoms of irritant poison. Magnesia was administered speedily and freely, by a neighbouring practitioner, and a stomach-pump was used, I imagine to effect the introduction of the antidote; and next morning, fifteen hours after the rash act she was admitted into the Infirmary (September 5th). The symptoms observed at her admission were the usual signs of the most acute gastritic irritation. There was no hæmatemesis; the bowels were confined; the pulse quick and feeble. Energetic measures were immediately taken, under the direction of my colleague, Dr. Sims, who kindly acted for me during my absence from town. From the 6th to the 16th, blood-letting by lancet and leeches was repeatedly employed, and the gastritic symptoms were so far subdued that, with the exception of a blister applied to the præcordia, to be dressed with savine, no important antiphlogistic means were considered necessary until the 20th of October, when recourse was again had to leeching. On the 16th I saw her, for the first time, and found

her greatly relieved, but thought it advisable to add prussic acid to her gum mixture. Under these she, in two or three days, so far improved, that, what with the mitigation of the symptoms on the one hand, and the wasting of the patient, and loss of power in the circulation, and calorific function, on the other, I was induced to venture on a little solid food and port wine. But in a day or two the gastritic symptoms (leeching, prussic acid, &c. notwithstanding) got ahead again, and never receded. On the 21st I had occasion to visit a distant part of Kent, and she died on the day of my return. On the 25th her remains were inspected. The principal morbid appearances were in the gullet and stomach; the tongue was shortened, and, as it were, humped, but without sloughs; from the tongue down to two inches from the rima glottidis, all was entire and pale, but a very little farther down there was sensible puckering of the mucous membrane, with opacity of the cuticle; about three inches below the rima were observed the first traces of ulceration, beginning at several different points in the circumference of the gullet, and extending downwards and laterally, so that somewhat lower down traces merely of the mucous and cellular linings were observable, in the form of elevated specks, in colour and hardness like cartilage; lower down still, viz. five to six inches from the rima, the muscular coat seemed quite bare. In the stomach there was ulceration and loss of substance at both the cardiac and pyloric extremities, with thickening and contraction of the apertures; the pylorus was thick and firm, and too narrow to give passage to an average-sized little finger; and in its immediate vicinity was an excavated spot, probably two lines in depth, and, as I conceived, the effect of the poisoning. The stomach was all over much injected and swollen, but the mucous lining had, with the exceptions already mentioned, suffered in texture little, save a spot at the great end, where there was softening and erosion. The patient had vomited almost immediately after swallowing the acid, and antacids had been administered with very little delay. This case, a notice of which was read to the Harveian Society (at a meeting at which I had the pleasure of seeing Sir David Barry in apparently the best health, though but a day or two before his loss to the profession), excited some discussion, which turned a good deal on a point to which I have not yet particularly adverted—viz. the use of purgatives in the after-treatment of this as a case of irritant poisoning. In this instance, as in the majority of such, there was obstinate constipation: enemata produced no satisfactory effect, and active purgatives were administered by the mouth. Croton oil was administered in two-minim doses six or eight times in the course of the first five weeks of treatment, and with due effect on the bowels, and without apparent countervailing disadvantage. Now the propriety of including purgatives in the remedial plan was disputed by several speakers, and amongst the number by the distinguished Editor of the Medico-Chirurgical Review, who favoured the society on that occasion by taking part in its proceedings.

The argument against the use of purgatives by the mouth was, as it appeared to me, conceived much in the speculative spirit of the French school, while the defence was conducted on the empirical principles of British practice. It was maintained that the introduction of acrid substances, such as croton oil, in cases of corrosive or irritant poisoning, is an application of irritants to parts already much injured, and highly irritable, &c. and not only unnecessary in point of fact, but dangerous in tendency; and that the natural efforts, aided by enemata, should be sufficient for all the defecation required. "Autant les purgatifs sont en général utiles dans ces maladies (engorgemens du foie), autant ils sont dangereux dans presque toutes les inflammations intestinales aigues et chroniques, particulièrement dans les gastro-enterites et les gastro-enterites, et les entero-colites ordinaires."—*Guersent, Dict. de Médecine, art. Purgatifs*; and the only other authority at hand, viz. Barbier, who writes the analogous article in the *Dict. des Sciences Méd.*, disapproves of purgatives in inflammatory fever (synocha, I presume), in inflammations of parenchymatous parts (as pneumonia, hepatitis), of serous membranes, &c. But it is not necessary to seek for authorities for the fact that the great physicians of France are generally indisposed to the use of purgatives, and but, as I should say, imperfectly acquainted with their value.

I have myself seen, I conceive, enough of the practice of the Hôtel

Dieu and La Charité, in the services of Laennec, Chomel, and Cayol, at the latter, and of Recamier at the former, to be able to affirm it of my own knowledge. Now none will deny that the opinions and practices of such men are to be viewed with deep respect; nor should I venture to refuse to the opinions of the clever but rash exclusive, the founder of the *soi-disant* physiological medicine, considerable weight; yet I cannot admit the high claims put forth by Gallic authorities for the *potion gommeuse* and *diete absolue*, as compared with the British substitutes of light or low diet, evacuation more or less free by purgatives and diaphoretics, and counter-irritation.

The French method, so far as mucilage and famine are concerned, is, in my opinion, at the utmost to leave nature to her own resources, to suffer the injured organs to right themselves if they can; while the British plan is, if I may so express myself, to endeavour to help them to do so.

1. Pungent lotions, gargles, ointments, &c., are in general use as applications to inflamed parts, and with success, on both sides of the channel. The principle of practice on which the objection to purgatives seems to be founded, and which is, I believe, briefly expressed by *contraria contrariis medentur*, does not, when rightly interpreted, mean that to parts in a state of irritation, or inflammation, no substance should be applied which is capable of irritating or inflaming healthy parts. The antagonism referred to by the ancient is not of a simply physiological character, and its laws and conditions are not best investigated chemically or physiologically, but by clinical trial and experience; and the aphorism may be translated or paraphrased for this occasion—"Irritation and inflammation should be treated with such agents only (irritants, excitants, stimulants, &c. included), as are known to subdue the species of irritation under treatment, and not at all with such as appear from experiment to aggravate it;" so that the admission of the truth of the aphorism to its fullest extent by no means implies the exclusion of purgatives from the treatment of cases of irritant poisoning.

2. British experience proves that purgatives are, in one state or other of combination, valuable remedies in many diseases in which gastric and intestinal irritation is in one degree or another undoubtedly present; *ex. gr.* every form almost of fever, enteritis, peritonitis, dysentery, recent diarrhœas, cholera, colics of every kind, &c. &c.

In addition to the security against the gastric and intestinal distention and irritation, so often arising from foul and fermenting excretions, it may be urged in favour of the British practice, that purgatives, when judiciously administered, not only neutralize the irritation they themselves have excited by the copious exhalations they occasion, but that their operation extends further, and that they diminish and remove preexisting irritations of the alimentary tube. How, in fact, should saline, oily, and other active purgative substances, simple or combined, prove useful, as they unquestionably do in intestinal irritations of most kinds, if it were not that exhalation, when judiciously excited, counterbalances the irritation of the stimulant applied to the exhaling tissues, while it at the same time roots up the morbid actions constituting the original disease?

On the whole I am disposed to think that purgatives by the mouth should have place in the armoury of the physician as one of many remedies for the after-treatment of cases of irritant poisoning; while I readily admit that, in several combinations of circumstances, it may be advisable to prefer the method of stimulating the bowels per anum.

STRUCTURE AND USES OF THE INTERVERTEBRAL SUBSTANCE.

To the Editor of the Medical Gazette.

Sir,

You will oblige me by giving the following remarks a place in your widely-circulated journal, should you deem them of sufficient importance.

I am, sir,
Your obedient servant,
Hamilton Labatt, A.B.
Demonstrator of Anatomy, Medical School, Marlborough-street.

Dublin, 1, Rutland Square,
Nov. 16, 1835.

Between the bodies of those irregular bones which constitute the spine, and form the connecting chain between the superior and inferior divisions of the human frame, we observe a remarkable fibro-cartilaginous substance interposed, which not only serves to protect the brain and spinal marrow from the effects of jars and concussions, but also, by enduing the whole column with a marked degree of springy flexibility, enables it to react on every motion of the body. So great, indeed, is the perfection and power of this great central spring, that we find, when the trunk has been thrown suddenly in the lateral direction, and the muscles commence their action to recover and restore it to a straight and steady position, a distinct vibratory or oscillatory motion is carried on in the lumbar region, before the contractile organs succeed in mastering and reducing the whole to a state of quiescence.

In examining the nature of the intervertebral substance, we find it composed of two distinct portions, differing both in their consistence and internal arrangement. The first we shall describe occupies the centre, and has been ingeniously compared to a central pivot for facilitating the motions of the vertebræ on each other. It is of a whitish colour, presents the appearance of a homogeneous and almost gelatinous mass, and possesses a considerable degree of elasticity, as is proved by its starting up and rendering the whole surface convex when a knife has been passed transversely between two vertebræ, and the pressure of the superimposed bones removed. I am aware that this portion of the intervertebral material is considered by some anatomists as quite inelastic; for the reason assigned, however, I must dissent from such an opinion.

Surrounding the central part, and confining it within its proper limits, we find the second or external portion. This is evidently of a fibrous structure, rather of a darker shade than that just described, and possessing a much greater degree of firmness and strength.

With respect to the fibres of this external division, which is likewise elastic, they are concentrically arranged, and assume a crucial direction with regard to each other. This is best displayed by taking a portion of the lumbar region of the column, and dissecting off the anterior common ligament; when, by slicing away a part of the intervertebral substance in front, we bring into view the substance alluded to.

The general opinion as to the above crucial arrangement, is that it serves to give a greater degree of elasticity and spring to the spine. This end I allow it answers. On considering the subject further, however, and on examining this peculiar provision in connexion with the motions which the column enjoys, I was led to a second important use; not as yet, I believe, proposed by any writer, and which I would therefore suggest as worthy of investigation. I mean, a power possessed by the crucial fibres of the external portion of the intervertebral substance, of limiting twisting motion; and, by their elasticity, of restoring the whole to its original position when the twisting effort is over.

With the view of following up this inquiry, I separated two lumbar vertebræ from the spinal column, preserving their articulations, &c. I then sawed off the posterior circles, in order to avoid, as much as possible, any interference with the free and independent motions of the bodies on each other; and having dissected away the anterior common ligament, I brought into view (in the manner already directed) the crucial fibres of the intervertebral material. By twisting the bodies on each other, I was now enabled to observe very distinctly the two orders of fibres, alternately relaxed and stretched. On the parts being left free, there was a spring back to their regular position. I may here remark, that so evident were the crucial fibres made by the above motions, that I would recommend the student who may wish to see them to adopt the course pursued by me.

Having so far established my position, the next point to be considered was, whether the crucial arrangement is as evident in those regions of the spine which do not admit of twisting motion, as in that which enjoys it in a very appreciable degree. To elucidate this, I applied my attention to the cervical division, where we know, from the peculiar mode in which the bodies of the vertebræ are locked into each other, no twisting can be effected. Here I found the crucial fibres, comparatively speaking, very indistinct indeed, and the substance becoming more homogeneous. Again, in the dorsal region, although

they were much more distinct than in the cervical, still they were not so well marked as in the lumbar, where twisting is principally enjoyed.

Between the atlas and vertebra dentata, we do not find any provision analogous to the intervertebral substance. The rotatory motion here is limited by check ligaments, which pass from the summit of the odontoid process of the dentata to be attached to the inner edges of the occipital condyles.

Before I dismiss the consideration of this important structure, I shall offer a remark on an opinion which is advanced in an article on Animal Mechanics, published in one of the numbers of the Library of Useful Knowledge. It is there asserted, that "when a weight is on the body, this gristly material is squeezed out from between the bones." From such an opinion I must certainly dissent; it bespeaks a degree of yielding and laxity which would by no means be compatible with the necessary safety and solidity of the whole; and moreover, the substance alluded to is confined by dense unyielding ligamentous bands, stretching along the bodies of the vertebræ, that I cannot conceive how such an occurrence could take place.

In conclusion, I would observe, that if the view which I have now put forth as to the use of the crucial fibres of the intervertebral substance be correct, we can readily see how we possess, in such a material, a provision which, whether we twist or bend the body, will always tend to restore it to the straight and upright position.

CASE OF INFANTILE AFFECTION OF THE SENSORIUM, SUCCESSFULLY TREATED.

To the Editor of the Medical Gazette.

Sir,

I trust you will consider the following brief outline of a case, which I have had recently under my care, of sufficient interest to receive a place in your valuable journal.—I am, sir,

Your obedient servant,

John Armstrong.

Gravesend, Nov. 10, 1835.

L. B., aged 2 years, of delicate make and complexion, with rather a large head, and possessing considerable vivacity and sensibility, was seized, whilst under the care of a relative at Chatham, with a convulsive fit, on the 7th of last August, from which she soon recovered, and no medical assistance was deemed necessary. On the 10th she was much frightened by a horse coming close to her; next day she had a much more severe fit, for which, finding she did not recover her senses, medical aid was obtained. The medical gentleman recommended leeches and blisters, to which the persons in charge would not consent. Some mild aperients were then prescribed, without benefit. On the 14th, finding no improvement, the child was taken home, and I was requested to visit her. The face is pale; she lies on her back; the skin cool; the eye-lids half cover the eyes, which seem to roll about in vacancy; the pupils act sluggishly, and a candle may be brought very close to the eye without any apparent consciousness; the pupils are rather dilated; there is equal insensibility to sounds, and pinching seems to give no pain; no voice nor sound has been uttered since the fit; there seems a total suspension of all the senses—not even the sense of taste seems to exist, as all substances, whether bitter or sweet, are swallowed indiscriminately; the pulse is feeble, and there is very little increased activity in the vessels of the head. From the known constitutional delicacy of the child, and the want of power in the circulation, I omitted bleeding, and incised the gums freely. The head was shaved, and covered with evaporating lotion. Blisters were applied behind the ears, and two grains of the hyd. sub. mur. were directed every four hours.

August 15th.—The bowels have not been relieved; blisters have acted slightly, without any apparent benefit. Powders of scammony and calomel were directed. In the evening she was seen by Mr. Park, of whose skill and experience I gladly availed myself. He concurred with me in the propriety of avoiding blood-letting, and recommended blistering the occiput, and keeping it discharging with the ungt. sabinæ, and to continue the calomel and scammony.

17th.—Bowels have acted freely; fæces exceedingly dark and offensive;

sensorium the same; pupils more staring; pulse feeble and intermitting. When the child is raised for any purpose, the head rolls as if all power of support was lost; total insensibility to light, sounds, or pinching; swallows any fluids pretty well. It was observed that there are periods of distinct easy sleep, which may be distinguished from the waking moments, if a state of insensibility to surrounding objects can be so called.

I shall not trespass on your columns by detailing all the particulars of this case; suffice it to say that an extensive discharge was kept up from the back and sides of the head; the calomel was steadily persisted in without producing any thing like ptyalism, until the 28th, when I ordered the following:—

> R Sol. Hyd. Oxymur. ℥iij.; Sp. Æth. Nit. ʒj.; Tr. Digit. gtt. xij.; Syrup., ʒij.; Aq. Cin. ℥iss. M. st. coch. j. med. 4tis horis.

This evidently increased the secretion of urine, but there was no apparent benefit; on the contrary, the powers of life seemed failing. I therefore ordered good beef tea, broths, and arrow root, with wine, keeping the bowels free with calomel and castor oil.

Sept. 3d.—Much the same, except that the left hand is observed frequently raised to the head; exceedingly low and weak, with a pulse scarcely perceptible.

> Quinine in small doses, and a larger allowance of wine, was ordered.

5th.—The motion of the hand seems somewhat like that of a person labouring under chorea; pulse more developed.

> Coch. Ferri was ordered in addition to the quinine.

From this period the child began to mend, and it was truly astonishing how rapidly she improved.

It was exceedingly interesting to observe the various stages of improvement. The sense of taste seemed first in order, as was evinced by her grimaces after the quinine. Sight next; the hand passed across the eyes caused winking. She began also to follow objects with the eyes for a short distance; and a faint smile was occasionally observed to alter the fearful and long-continued composure of the countenance. I now ventured, in answer to the anxious inquiries of the parents, to assure them that voice would also soon return, and that the intellectual faculties would be restored. She could, however, run about the room, play, smile, &c., but no voice was uttered to relieve our anxiety.

27th.—Sounds have been attempted, which have gradually become more determinate; and the vacuity of countenance has greatly diminished.

Oct. 20th.—rapidly improving. The only complaint is that the child seems disposed "to run about too much, and stuffs every thing into the mouth," probably owing to dental irritation; but speech, taste, feeling, hearing, &c. are restored.

The above case was to me and the friends one of the most intense interest, and the pleasing issue of no small gratification. It has appeared to me to have some points very similar to a case reported in the Gazette a short time back, from Professor Badham, though obviously attributable to a very different cause. I feel persuaded that depletion in my case would have been attended with bad consequences, as I have no doubt it was the cause in his; yet I must say, I think the severity with which he has visited his brother's error (and who is not liable to err?) is by no means commendable.

REPORT OF FRACTURES

TREATED IN THE LONDON HOSPITAL DURING OCTOBER.

To the Editor of the Medical Gazette.

Sir,

I inclose you the report of fractures admitted into the London Hospital during the month of October.

I have selected one case for especial notice. It occurs under the head of fractured fibula; this was complicated with a compound dislocation of the tibia inwards.

I am, sir,
Your obedient servant,
John Adams.

New Broad-Street,
Nov. 1835.

		Right.	Left.	Unknown.
Cranium	2	0	0	0
Spine	1	0	0	0
Sternum	1	0	0	0
Ribs	7	3	3	1
Scapula	1	0	1	0
Clavicle	6	1	5	0
Humerus	10	4	6	0
Fore-arm (both bones)	1	0	1	0
Ulna	4	1	3	0
Radius	2	2	0	0
Hand	4	4	0	0
Femur	4	2	2	0
Leg (both bones)	2	1	1	0
Tibia	2	0	2	0
Fibula	5	4	1	0
Toe	1	1	0	0
	53	23	25	1

Oct. 12th.—Joseph Dark, æt. 45, a groom in a gentleman's family, whilst carrying a load up a ladder, his foot slipping, was precipitated, and fell upon the inner side of the right foot. It was twisted up, and the tibia passing off the upper surface of the astragalus, the inner malleolus protruded through the skin for the distance of at least an inch and a half. The fibula was fractured at about the distance of three inches above the outer malleolus. No very serious injury of the soft parts adjacent was visible. The minutest fragment of bone was felt in the wound, but this eluded my attempts to extract it. Shreds of the internal lateral ligament were adherent to the lower end of the tibia. The foot was in the position common to such accidents. By flexing the knee-joint, and forcibly drawing down the foot, it was speedily and easily reduced. The leg was laid upon the outside, with a splint with a foot-piece beneath it; and the wound was accurately brought together. Cold lotion was applied, and at night forty drops of laudanum were given.

13th.—The leg is painful, and there is a slight oozing of bloody discharge from the wound. Some febrile excitement is visible.

Ordered saline mixture, with ten drops of laudanum every six hours.

From this period an erysipelatous inflammation commenced in the leg, and extended up the thigh; this was attended with considerable fever, and a dusky red appearance of the skin about the knee. He lost a small quantity of blood, and the same medicinal treatment was pursued, with attention to the condition of the bowels. He appeared mending, but suddenly sank on the 19th.

Sectio cadaveris.—Suppuration within and around the joint. The tendons in its vicinity were all entire. Evident marks of diffuse cellular inflammation were seen along the leg, the cellular substance being infiltrated with pus. The whole limb exhibited signs of diffuse inflammation. A slight slough was observed on the outside of the leg, and the skin in the vicinity of the nates appeared to be approaching to a gangrenous condition.

The abdomen contained a quantity of bloody serum; and in the vicinity of the liver the intestines were covered with a semifluid substance like coffee-grounds. The intestines were distended with flatus, the peritoneal covering exhibiting marks of preternatural injection. The brain much more vascular than usual; its veins distended. The arachnoid opaque; considerable quantity of fluid beneath this membrane, and especially at the basis.

I scarcely think it fair to bring this case forward to militate against the position laid down by Sir Astley Cooper, of the propriety of attempting to save the limb under circumstances like the present, but I am bound to say that the results of the generality of cases that I

have witnessed in hospital practice, have induced me to form a very guarded opinion as to the ultimate success of such an attempt.

In the present instance, so far as the joint itself was concerned, nothing of a very untoward nature had arisen; but the patient seemed to have sunk from the effects of diffuse cellular inflammation, occurring in a constitution not of the most vigorous description.

ON THE

NERVOUS INFLUENCE AND ANIMAL HEAT;

IN REPLY TO DR. WILSON PHILIP'S LAST LETTER.

To the Editor of the Medical Gazette.

SIR,

DR. WILSON PHILIP is mistaken in supposing that by referring to the writings of others I meant to reply conclusively against his position, or to "determine the point by a majority of voices." The opinions of others were quoted to show that, from the facts hitherto known, opposing conclusions were drawn by different physiologists, and that the "legitimate inference" of Dr. Philip is denied to be such by other writers. These writers have stated the grounds of their dissent; in their works, and in those of Dr. Philip, the reader may study the facts and arguments on either side. There, in my opinion, discussion has already done its utmost; and as the "legitimate inferences" of the several writers are remarkable for their diversity, I may be well excused from unprofitably occupying the pages of the Medical Gazette with the details of an unsettled controversy, which are already before the public.

Before I quit this subject, I must, however, correct the interpretation and answer which Dr. Philip gives to a statement which I had quoted from Dr. Alison. The passage is this:—"The province of the nervous system in producing the phenomena of life, which was long neglected in certain schools of medicine, has been erroneously conceived in others; by Stahl, by Cullen, and Whytt; and to a certain degree by Bichat, by Legallois, and even by Dr. Wilson Philip; and was more accurately understood by Haller than" (not, as Dr. Philip adds, "in the present day," but) "*by any of these writers**."

That Dr. Alison does not here deny, what I have stated, that the researches of Dr. Philip and other recent inquirers have greatly increased the precision and extent of our knowledge, may be inferred from his frequent reference to the *facts* obtained in those researches; and it is equally clear from the context of his remarks, that it is in regard to *general conclusions* respecting the functions of the nervous system that Dr. Alison asserts the superior accuracy of Haller.

As the legitimacy of Dr. Philip's inference, adverted to in the first part of his letter, thus appears to be, to say the most of it, a matter of opinion opposed to opinion, so in his following observations we find his statement of a fact opposed to a fact described by a later observer. Dr. Philip states, on the authority of his own experiments and those of Legallois, that the gradual destruction or simple removal of a part, or even of the whole of the brain and spinal marrow, produces no effect whatever on the circulation. Dr. Marshall Hall concludes from his experiments on frogs and fishes, that the simple removal, or cautious destruction (without shock), of the brain and spinal marrow, is uniformly followed by a gradual failure in the capillary circulation, this failure beginning in parts most distant from the heart†. Between these conflicting statements I do not pretend to decide, for neither of them materially affect my view of the causes of animal temperature; but I may remark that in the experiments of Dr. Philip, to which he refers, it does not appear that the capillary circulation was examined so long as in those of Dr. Hall.

Dr. Philip next shortly adverts to the experiments which I had cited from Chossat, and remarks, that it could easily have been foretold that bruising the semilunar ganglion, or tying the aorta, would greatly impair the temperature, "because the one deprives the

---

* Dr. Alison's Outlines of Physiology, &c. 2d edition, 1833. Preface.

† Essay on the Circulation, &c. 1831. Page 118 and seq. In my last communication these experiments were by mistake said to associate injuries of the spinal marrow only, with failure of the capillary circulation. The removal of both brain and spinal marrow was necessary; and then, within half an hour, the circulation in a frog's web ceased entirely, although the heart still continued to contract.

blood of a great part of the nervous influence, by the action of which on this fluid animal temperature is maintained, and the other prevents the due supply of the blood itself." Dr. Philip forgets that the effect of these operations, as described by Chossat, was not such a slow dimiuution of heat as that which results from destroying even large portions of the spinal marrow, but as rapid a cooling as that caused by the removal of the brain itself. Bruising the semilunar ganglion produced a more speedy cooling than the division of the spinal marrow at the upper dorsal vertebræ; and tying the aorta below the diaphragm made the animal cool as fast as when the brain and medulla oblongata are removed; and this cooling was equal in the œsophagus, which was still supplied with blood and nervous influence, and in the rectum, which, according to Dr. Philip's views, ought to have been exclusively or chiefly affected.

Now bruising the semilunar ganglion cannot destroy the functions of the brain and spinal marrow, which Dr. Philip says are "the only active parts of the nervous system;" nor, in his view, can it act by intercepting the influence, for he tells us that "the maintenance of animal temperature depending on functions which take place in every part of the system, and these being, like the other assimilating processes, functions of the central parts of the nervous system, can only be generally influenced by causes which influence the functions of these parts, *not by causes which prevent their influence from reaching particular parts of the body**."

So also, according to these views, tying the abdominal aorta ought to affect the temperature only as much as dividing the spinal marrow at a corresponding point, the part below which it can only incapacitate; whereas Chossat found its effect to be as great as that of the destruction of the brain and medulla oblongata, and greater than the effect of destroying the whole spinal marrow. These experiments, then, are signally opposed to Dr. Philip's views, whilst they strikingly illustrate the connexion of animal heat with secreting organs which receive their blood from the artery which was tied, and are remarkably influenced by the ganglionic system which was injured.

The fact which I adduced in my last communication, that heat is evolved in oxygenated blood out of the body, is ascribed by Dr. Philip to *nervous influence remaining in the blood*. Now this notion, and that of the influence remaining in nerves separated from the cerebro-spinal axis, must be judged by the view which Dr. Philip holds of the nature of this influence. He considers it to be voltaic electricity.

Now I may venture to affirm that there is no known property of voltaic electricity which could enable it to act in a nerve or in blood after its source of supply is cut off. The chemical properties of voltaic electricity exist only in its currents; and unless electricity be excited anew in the separated nerve or blood, there can be no currents in them. Electricity is not a ponderable agent, that can be stored up in a nerve, or retained in an active state in a cup of blood. We can, it is true, accumulate it in bodies by means of insulation and of induction; but there are no such means in the nerves or in the blood, in which an equal diffusion of electricity, and, therefore, a cessation of its activity, must ensue the moment that the current ceases. It is, I repeat, by unequal distribution, and by the currents which ensue to restore its equality, *and by these alone*, that voltaic electricity can heighten, control, or modify chemical action; and unless there be a source of such currents, there can be no disturbing electrical force. For the truth of these positions, I need only refer to the latest and best authority, in the masterly series of researches of Professor Faraday, contained in the Philosophical Transactions.

If, then, the nervous influence is voltaic electricity, it cannot be concerned in producing the heat evolved in blood out of the body. I have shewn that this evolution of heat may be fairly referred to the chemical changes that are known to accompany it. That *electricity is* NOT *the cause* of the heat in question, is thus proved by a reference to the known laws of electricity. That *chemical action* is *the cause*, is supported by what we know of the laws which regulate chemical action.

But in the next paragraph which I

* Med. Gaz. Nov. 7, p. 173.

have to notice, Dr. Philip assumes a position which, if it have any strength, is quite at variance with his preceding arguments, and totally destroys their force. The passage is too long to be repeated, but I would beg the reader to turn to it. (See the last paragraph of page 272, in Med. Gaz. Nov. 21.) Dr. Philip there argues thus: The chemical changes of inanimate nature depend on electric action; the same changes take place in the living body: to suppose the principle of action in these identical cases to be different, is absurd; *therefore* the chemistry of the living animal must depend on electric action, *which is the nervous influence.*

Your readers are aware that the electrical theory of chemical action very generally prevails among the chemists of the present day; and no fact has tended to support it more than the beautiful discovery of Professor Faraday, that there is an exact relation between the forces of electricity and those of chemical attraction. But this theory obviously supposes the electricity of chemical agents to be within themselves; and although chemical change is necessarily attended with a change in the relation of this electricity, it is still according to chemical laws, and independent of external agency.

In appealing to the electro-chemical doctrine, therefore, Dr. Philip adduces the electricity of inanimate chemistry, and thus supersedes the necessity of the electric power which he attributes to the nerves. To take his own example: carbon and oxygen (he intimates) unite in the blood on the same principle as in the laboratory of the chemist—that is, on the principle of electric attraction; but in the laboratory of the chemist this attraction depends on the intrinsic electricity of the uniting matters, which, being sufficient in this case, are sufficient, without the supposed nervous electricity, in the other.

To attribute to electricity all the phenomena in which its presence may be detected, is about as logical as to attribute to gravitation all the phenomena which ponderable bodies exhibit. An explanation in physiology, as in physical science in general, is the reference of a fact to known laws; and until voltaic electricity be proved to possess more properties than those by which it is at present known,—until some new laws be traced in its operation,—the view of Dr. Philip, which identifies voltaic electricity with the nervous influence, can be regarded only as an ingenious hypothesis. It is, perhaps, estimating it beyond its value, to compare it with the relation of magnetism to electricity in the time of Œrsted's first discovery; but the comparison will illustrate its position, and may stimulate the minds of future inquirers.

Œrsted found that an electric current affected a magnetic needle in a definite manner; but until, by further study, the laws of the relation of electricity to magnetism were made known, and until electricity was made to exhibit all the properties of magnetism, and magnetism to evolve electricity in its distinctive characters, no philosopher admitted that their identity was proved.

So Dr. Philip and others have shown that electricity affects certain vital functions in a definite manner, and that the living nerves in a single point resemble conductors of electricity. But until it be shown that these relations are not secondary,—until the distinctive properties of electricity be detected in the influence conveyed by the nerves, and the nervous function be not only imitated, but effectually performed by electricity, —the identity of the powers cannot be considered as established.

In these last remarks I may have somewhat exceeded the limits which I had prescribed to myself, and entered on a subject not essentially connected with my views on animal heat; but the observations in Dr. Philip's last letter have unavoidably led me to these observations, and I trust that they are sufficient to substantiate the opinion which I gave on this subject in my first letter.

I am, sir,
Your obedient servant,
C. J. B. Williams.

Half-moon-Street,

TREATMENT OF NÆVUS.

To the Editor of the Medical Gazette.

Sir,

Having read the report, in last week's Gazette, of three cases of nævus, treated by M. Lallemand, I beg to give you a

case treated by me, with complete success, upon the plan laid down some time ago, in your journal, by Dr. Marshall Hall.

Miss W——, 3 years of age, had, from her birth, a nævus occupying the apex and septum of the nose, which produced a very unpleasant appearance: its surface projected, and had the resemblance of a ripe raspberry.

On the 14th of May last, I punctured the nævus in every part with needles, and repeated the operation on the 28th.

At the end of a fortnight I observed a manifest diminution of the vascularity.

On the 24th of June I again punctured it as before. From this time it has been gradually diminishing in vascularity and elevation of surface, and at the present time there is not the least appearance of nævus remaining, the part resembling, with regard to vascularity, any other part of the face.

By inserting this brief account in your next number, you will oblige,

Sir, yours truly,
RICHARD WALLACE,
Surgeon.

Hackney Road, Nov. 30, 1835.

P.S.—It will be remarked that the seat of this nævus was such as to render the knife, the ligature, or the caustics, altogether inapplicable; the scar induced would have been a greater deformity than raspberry-like nævus itself.

The progress of the cure was extremely slow. Not having seen the case recently, I told Dr. Marshall Hall, yesterday, that I believed a point still remained of the original hue; but having visited my little patient this morning, I find that since my last visit that spot also has gradually and entirely lost its vascularity. It is important to remember this slow progress of the cure, in order to prevent undue expectations, and consequent disappointments. It is now more than six months since the first acupuncturations were performed.

I must admit that I know not what other plan of cure *could* have been adopted in this instance. This mode of cure must therefore be deemed of great value; and not the less, because it is attended with scarcely any pain, hæmorrhage, or other inconvenience.

ON THE SMALL SIZE OF THE PELVIS IN RICKETS.

To the Editor of the Medical Gazette.

SIR,

THROUGH the kindness of Mr. Sweatman, I have had the opportunity of making the accompanying drawing of a pelvis affected by rickets (fig. 2), with the view of contrasting it with the natural pelvis. It was taken, within these few days, from a female, æt. 28, who died from peritoneal inflammation, after having been delivered by the crotchet. She had the common appearances of being deformed by rickets; her shin-bones were curved forwards; yet the distortion was not very great. She had gone her full time, and had been three days in labour before she was seen by Mr. Sweatman. The head of the child had not descended into the true pelvis, and nearly an hour was occupied in completing the delivery, although the child was rather below the average size of a full-grown fœtus. Her death occurred nine days after delivery; and on dissection, besides the peritoneal inflammation, the inner surface of the uterus and that of the bladder were found to have suffered severely from the bruising of the child's head, so as to be in a state approaching to gangrene.

My object in presenting these drawings to the notice of your readers, is to point out a circumstance which I do not find touched upon by writers on midwifery in treating of rickets, and which yet appears of great importance: I mean, the smallness of the pelvis that results from the imperfect development of the bones which compose it. These authors, as well as the best writers on the pathology of the bones, confine their observations on the condition of the pelvis to the distortion which is consequent on the softness of the bones, and the pressure of the superincumbent weight; and attribute all the dangers met with in such cases, in parturition, to that cause alone.

Now in the pelvis (fig. 2) which is here represented, it is apparent that there is very little distortion of the bones. The promontory of the sacrum, it is true, has been thrust forwards to a slight degree, so as to destroy the pro-

Fig. 1.

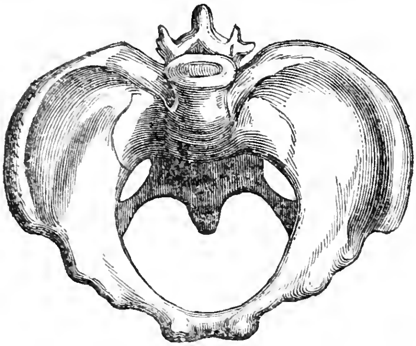

Fig. 2.

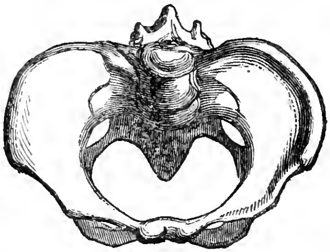

per oval form of the inlet; but this has only taken place to a trifling extent. Yet, when we contrast this pelvis with the pelvis of the natural size, placed beside it (fig. 1), we cannot but be struck with the remarkable smallness of the brim of the former, and how impossible it must have been for a full-sized fœtus to have passed through such a pelvis in a natural manner: and it is not only the antero-posterior diameter that is diminutive — which we might expect, from the sacrum projecting forwards; but the oblique and transverse diameters, which it might be supposed would be enlarged by the change in the form of the bones, are likewise diminished. In short, looking to the remarkable difference in the size of the two pelves, we cannot doubt that, in this case, it was the small size of the bones composing the pelvis, and not the deformity occasioned by the softening of their textures, that was the cause of the death both of the parent and child.

With the view of showing that the present case is not merely a singular instance of a small-sized pelvis occurring in a rickety person, but that this smallness of the pelvis is a common character in those who have been affected with this disease, I may be allowed to refer to a paper* which you did me the favour to insert in a former number of your journal, on the same subject. In that paper I gave a table containing the measurements of numerous rickety skeletons and pelves, obtained from different museums, and contrasted them with corresponding measurements of the natural bones. By such a comparison, it was shown that the disease in question, at the same time that it gave rise to softening of the textures of the bones and distortion, had the effect of arresting the growth of the whole skeleton. And another interesting circumstance was made evident. It was proved that in this stoppage of the growth, certain parts of the skeleton suffered to a greater extent than others. The several divisions of the skeleton having each an appropriate rate of growth, some undergoing a more remarkable change in their dimensions, during the period of growth, than the rest, it was found that those bones which naturally acquire the greatest increase of size were the most visibly affected by the development being arrested.

It will be acknowledged that there is no part of the skeleton that, in natural circumstances, exhibits a more extraordinary difference in its size, at birth and at adolescence, than the pelvis; especially in the female. Accordingly it was proved, from the measurements referred to, which included twenty-nine specimens of rickety pelvis, that this circle of bones suffered more extensively in its dimensions, from the effects of the disease, than any of the other parts of the skeleton. And the estimate which I made, by taking the average of the measurements, and comparing this with the natural measurements, marks how important it is to take this subject into consideration, for I was brought to the conclusion, that the diseased pelvis was defective in its growth, within a small fraction, to the extent of a quarter of the natural size of the pelvis.

This calculation corresponds with

* See the last volume of the Medical Gazette, p. 45. See also a paper in the Medico-Chirurgical Transactions, vol. xvii.

the difference of size in the rickety pelvis and the natural one which are here represented in contrast: as may be seen by consulting the table below *. The average of the measurements of the diseased pelvis, taken in six different directions, is $5\frac{1}{2}$ inches, while that of the natural pelvis is 7 inches: and $1\frac{1}{2}$, which marks the difference between them, is between a fourth and a fifth of the number representing the natural dimensions.

I am unwilling to encroach further upon the valuable space of your journal, or I might have touched upon the peculiarities to be remarked in the relative proportions of the skeleton affected with rickets, and contrasted with these the effects produced by an acceleration of the growth, in persons who are overgrown, instead of being thus stunted in their growth; and such questions might have illustrated what has been stated concerning the pelvis. It is also apparent how important it is to determine the period of life when rickets prevails; and to be able to distinguish between the distortion which it gives rise to, and the common lateral distortion of the spine; for the latter kind of distortion occurs before the growth of the pelvis is completed, and with greatest frequency in females, and has, moreover, been attributed by numerous writers to the influence of rickets. I may be allowed to state that these points are discussed in my former communication on this subject, in the last volume of the Gazette, and in the paper in the Medico-Chirurgical Transactions.

Every one knows that in a natural delivery the child's head undergoes a series of changes in its position upon its own axis; and that these are caused by the peculiar form of the head, and the points and surfaces of the pelvis being in succession opposed to its descent. Distortion of the pelvis alone will, therefore, derange the natural stages of labour, delay the descent of the head, and consequently exhaust the mother. In this way, a distorted pelvis, even if the diameters were very considerable, would call for the assistance of the accoucheur. But in the rickety pelvis there is an additional cause of protracted labour, depending on the diameters and whole cavity of the pelvis being deficient in size, from imperfect development; and that which I have drawn proves, from the fatal effects that it gave rise to, what a formidable source of danger there is in this smallness of the bones, even although the deformity be so slight as scarcely to be perceptible.

I have the honour to be, sir,
Your obedient servant,
ALEXANDER SHAW.

Middlesex Hospital School,
Nov. 23, 1835.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Médecine légale, théorique et pratique. Par ALPH. DEVERGIE, D.M.P., Professeur Agrégé, &c.; *avec le Texte et l'Interprétation des Lois relatives à la Médecine legale, revus et annotés* par M. DEHAUSSY DE ROBECOURT. Tome premier. 8vo. pp. 724. Baillière.

A GRAND fault fallen into by most authors who have hitherto produced works on legal medicine, has been, to dogmatize immoderately; to lay down as positive what can only be determined with probable exactness. Forgetting but too frequently the serious—we might say the awful, responsibility attaching to medico-legal research, when applied

in aid of the administration of justice, they assert, where they should only indicate with reserve. Of this class was the late Professor Foderé, the great object of whose life seems to have been to sift out the truths which he thought were to be found among the chaffy masses of *facts* (so called) and opinions gathered into the garners of medical science. His *Traité de Médecine légale* was unquestionably at the time it was written, and for many years after, considered to be a masterly performance: estimated in point of learning and comprehensiveness of plan, it is still a highly valuable work: but it has the besetting sin of attempting to *fix* every disputed question—to leave nothing unsettled.

Almost in the other extreme we find M. Orfila: he saw, perhaps, the too easy confidence displayed by his elder contemporary, and determined to avoid that sort of feeling altogether. In consequence, he may be observed, in his anxiety to set a proper value on each isolated fact, neglecting to state what he conceives to be the combined value of the whole; and thus, by directing all his attention to the errors which medical men in their medico-legal capacity may possibly commit, by laying before them chiefly a chart of the bearings which they are *not* to follow, he leaves the mind in a sad state of uncertainty—unfavourable in a marked degree to the promotion of any description of knowledge.

The author of the work before us, M. Devergie, has rightly chosen to take the middle course. There are facts, he says, in legal medicine, as well as in practical medicine, and resting upon as sure a foundation. The diagnosis of a disease is never founded on a single symptom, but on a sufficient group of morbid manifestations: such also is the legitimate mode of arriving at results in forensic medicine.

In his introduction, M. Devergie pursues the analogy still further between the two kindred arts of medicine, properly so called, and forensic medicine; and in his practical way wishes to know why, when the importance of the study is unhesitatingly admitted by all who direct their attention to the subject—why there are not at least equal facilities afforded for the cultivation of each? "The student," he says, "who aims at being a mere practitioner, has the course clear before him: he repairs to the hospitals, where he sees with his own eyes, obtains experience through personal observation, and avails himself also of the experience of his masters: and thus he at length proceeds, equipped for practice on his own account. But this is not the case with the student of forensic medicine; all the instruction he receives in this department, as at present conducted in France, is by theory alone. He learns nothing practically: toxicology perhaps he may—that is to say, he witnesses a series of precipitations and chemical changes which pass rapidly in review before him; but when or where is he permitted to make a single actual experiment in chemistry, or to examine a person found drowned, or hanged, or asphyxiated? We assert that there is nothing so grievously wanted in the French schools as a medico-legal arrangement similar to that for teaching clinical medicine—where the student may obtain that *practical* knowledge without which he is unfitted for the due fulfilment of his mission."

How aptly does all this apply to the state of things among ourselves! How much more deplorably off, however, we are, even in respect to the theoretical opportunities alluded to by M. Devergie, we need not describe: we shall have some time to wait, we imagine, before we arrive even at the imperfect condition of medico-legal instruction complained of by our French friends.

But let us direct our attention to the volume. We are struck, in the first place, by the order of subjects adopted by M. Devergie. He affects, we perceive, in his Preface, to think order, in a work on forensic medicine, of no great consequence—of none, in fact; but we must here beg leave to differ with him: principles are to be taught in this study as well as in others belonging to the extensive range of medical science; and if age and sex, for example, constitute elements in determining identity, why should not the peculiarities of sex and age be treated of previously to entering on the consideration of identity? The peculiarities of sex, too, we presume, should precede the exposition of the doctrines respecting violation and pregnancy; and so with numerous other instances which might be adduced. But M. Devergie himself, it seems to us, *has* followed a certain natural order, at least after his first two chapters.

These relate to reports and formalities connected with French law, which are disposed of in the opening chapter; the second, which, by the way, is enormously long, occupying more than a third of the volume, contains all that relates to the dead—changes undergone in the dead body, the art of opening bodies, and the methods adopted in juridical exhumations. After this, rather abruptly, the scene changes to violation; but marriage follows; then pregnancy, parturition, and births. Infanticide comes next; then abortion, viability, and paternity, close in the rear; so that, perhaps, so far there is no objection to be made to M. Devergie's order.

In a work of this kind it would be unreasonable to expect an author to be wholly, or for the greater part, original. M. Devergie does not aim at it; he judiciously selects, for the most part, from every available French source. We have rarely met with any reference to an English authority; this, however, we can scarcely quarrel with; but that the many valuable German writers on the subject are not freely consulted is a fault—one, however, with which M. Devergie is not singularly chargeable; his countrymen generally seem to entertain a sort of national jealousy of their neighbours beyond the Rhine, if, indeed, their want of acquaintance with the German language be not at the heart of the mystery.

We should be glad to offer a specimen of the author's mode of treating his subjects, could we find any thing to extract of a moderately reasonable length. But probably we have said enough to give the reader a general idea of the production: we may return to it again when the second and concluding volume makes its appearance. That the second *will be* the concluding volume we almost have our doubts, when we recollect all the subjects that remain to be treated in it: unsoundness of mind, feigned and concealed diseases, wounds, and, above all, medico-legal toxicology. We shall not complain, however, if, at whatever length, these subjects be only discussed with the same ability displayed in the present volume.

Those who are curious about French law, as relates to all those questions on which medical evidence is given or required in courts of justice, will find it here fully set forth and clearly expounded.

Genera Plantarum Floræ Germanicæ iconibus et descriptionibus illustrata. Auctore TH. F. L. NEES AB ESENBECK. Fasc. I. ad VII. Bailliere.

THIS elaborate and elegant production we look upon as quite a boon for the botanist, it is published at so extremely moderate a price—each fasciculus containing twenty beautifully-executed plates, and forty pages of letter-press! The author's name is a sufficient guarantee for the accuracy and fidelity of the representations; and we are sure no votary of botanical science will be without the work. Among the minute and splendid dissections here figured, we may particularly notice those of nine genera of coniferæ, admirably illustrating Mr. Brown's view of the structure of the female flower. The anatomy of orchideæ (a most difficult though very interesting family) is delineated in seventeen plates, and comprehends dissections of no less than seventeen genera. Besides these two, the seven fasciculi now published contain other families, namely, betulaceæ, cupuliferæ, plantanaceæ, salicinæ, typhaceæ, acroideæ, aroideæ, junceæ, juncagineæ, veratreæ, sarmentaceæ, miricaceæ, juglandeæ, ulmaceæ, artocarpeæ, urticeæ, euphorbiaceæ, empetraceæ, eleagneæ, sontalaceæ, junceæ, siliaceæ, irideæ, amaryllideæ, colchicaceæ, lemnaceæ, fluviales, hydrocharideæ, alimaceæ, butomeæ, thymelaceæ, laureæ, chenopodiaceæ, and amarontbaceæ.

We strongly recommend the work on the ground of its exceeding merits: it is, moreover, adapted for the patronage and purchase of every class of botanical students — not only the tyro, but the adept and proficient.

MEDICAL GAZETTE.

Saturday, December 5, 1835.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

THE METROPOLITAN UNIVERSITY.

WE are glad to announce that every thing is now arranged for the establish-

ment of the long-desired central University in the metropolis. It will of course be styled the University of London; an appellation which, though usurped and grossly misapplied for some years back, through the interested and selfish eagerness of the managers of a proprietary school, will soon be restored to its right use.

Of the details of the charter we have before us an authorized statement, as well as a communication from the Chancellor of the Exchequer, explaining some minor particulars, regarding which it might be satisfactory to the public to have fuller information. Scruple about laying before our readers as much of these documents as we please, there can be none; for although the right hon. Chancellor only consented to have his letter *privately* circulated, one of the ministerial papers (the *Globe*) was the first to disregard the restriction, and it has since made its way into other public journals.

The following are the principal points worthy of notice in the official paper alluded to:—

"The school hitherto calling itself the University of London, is to receive a charter of incorporation, with the style and title of 'London University *College*.' Similar charters are to be granted to other institutions of the same kind.

"Another charter will be granted to persons eminent in literature and science, to act as a Board of Examiners, and to perform all the functions of the Examiners of the Senate House of Cambridge;—this body to be termed the 'University of London.'

"Pupils from University and King's College, and from any other bodies, whether corporated or uncorporated, hereafter to be named by the Crown, are to be admitted to examination for degrees on certificates of having gone through a course of study at those establishments, and having obtained a proficiency for a degree; the said pupils to be examined and classed according to their relative merits.

"The same conditions to be applied to degrees in Medicine.

"The degrees to be granted by *the* University are those of A.B., A.M., B.L., D.L., B.M., and D.M.

"The Crown to have the power of appointing new and additional Examiners from time to time.

"The Secretary of State to have the chief control in the formation of all bye-laws and regulations for the government of the University.

"The King to be visitor.

"Fees to be charged on degrees, for the remuneration of the Examiners; the amount to be regulated by the Treasury."

From Mr. Spring Rice's letter of November 22, we select the following passages:—

"It should always be kept in mind, that what is sought on the present occasion is an equality in all respects with the ancient Universities, freed from those exclusions and religious distinctions which abridge the usefulness of Oxford and Cambridge.

"These points (relative to the *subjects* of examination) cannot be included in the charter, as in that case great difficulties might arise in their future modification from time to time, as circumstances may require. But they will necessarily form part of those laws and regulations which would be framed by the University, with the approval and sanction of the Secretary of State, and be thus made subject to the parliamentary responsibility of that officer of the crown. The principle of the absence of all religious tests and distinctions must, however, be set forth distinctly in the charter, so as to preclude any possible doubt or alteration hereafter.

"It cannot but be expedient that Parliament should hereafter, when legislative authority is required, and the intentions of the donors do not preclude such a step, extend to these metropolitan degrees all the privileges and advantages (not of an ecclesiastical character) which are connected with degrees at Oxford and Cambridge. This, of course, applies to civil rights and professions, and not to private endowments.

"It is not proposed, at least at present, to connect with degrees any rewards beyond the classification for

honours of the pupils examined; but a provision will be made by charter for receiving endowments, the subjects for which such endowments are made being first approved of by the University.

"It will be most desirable, according to my views, that wherever collegiate or other institutions are found to exist, *whether in London or elsewhere,* that if such establishments afford to the public adequate security for good education, they should be included within the system created previously for the metropolis."

Such are the chief particulars relative to the new foundation which we think most deserving of notice: others of a minor nature we are obliged, in our limited space, to omit: they relate merely to the number (as yet unlimited) of the Examiners,—the possibility of assistant-Examiners, "for the techinal purposes of examination," being occasionally called in,—and the propriety of adopting a written form of examination, as far as it may be practicable. We have no hesitation in saying that on the whole we consider the arrangements to be at once conceived in a spirit of strict impartiality, and likely to afford a high degree of satisfaction to the public.

All the existing respectable establishments—the general schools and schools of medicine, both in London and the provinces—as it seems to us, will be materially benefitted by the new arrangement. One alone must feel peculiarly situated—must feel sorer than it pretends. The Gower-Street school, in fact, in two or three respects, can scarcely be accounted a gainer by the change. In the first place, it is obliged to resign, however reluctantly, what Mr. Tooke calls "the vanity of its title:" the self-imposed and tenaciously maintained appellation of University of London is henceforth to be appropriated to the legitimate body which it is to designate. So far the school in question loses the opportunity of flourish and puffery, which is carried on to so very considerable an extent—with what success, remains to be seen. Then, again, by the settlement of the question—of providing a Metropolitan University, to accommodate the Dissenters, and persons of every religious persuasion—the struggle being now over—the public can no longer be importuned by the ever-obtruded claims of a joint-stock proprietary, keeping up an eternal jangle of discord, and contending for the possession of rights to which they were as much entitled as any of the islanders in the South seas. In addition to this, the said joint-stock establishment—having henceforward, *perforce,* to settle itself down in the same rank with other similar metropolitan institutions—will have to rest its pretensions to the favour of the public solely on its merits and its good behaviour. Upon all these several grounds we think the friends of order may congratulate themselves on the change that has taken place.

It is rather amusing to observe the tone and manner in which the new order of things has been received in Gower-Street. First, in the course of the summer, or rather just in the advertising season, out comes Mr. Tooke with his blustering appeal, in high dudgeon, upon hearing from the Attorney-General that the *proper* charters were ready. The ludicrous production of the learned solicitor we had occasion to examine some time since, and to appreciate at its due value. Next forth comes the *Senate* (save the mark) with an address to the *Council,* smoothing down all difficulties, reconciling, or attempting to reconcile, inconsistencies, and, in short, proving to the *satisfaction* of the proprietors (for whom the address was evidently principally intended), that the projected metropolitan Univer-

sity was just the thing wanted, and that it would have been a most foolish measure to grant to such a school as *theirs* the exclusive power of granting degrees in London.

Finally, a special meeting of the proprietors (on Wednesday last) takes place, when, after much speech-making, —Lord Brougham in the chair—a resolution is adopted to this effect:—" That his Majesty's Ministers, *having discovered a plan* for conferring academical degrees more comprehensive and efficient than that originally contemplated, by extending to all qualified colleges for education equal facilities for obtaining degrees, this meeting, &c. recommends the Council to *accept the collegiate charter* offered." Thus, with a *good* grace (and same time knowingly enough), have the parties determined to make a virtue of necessity; they have struck the bargain, intending, no doubt, to make the best of it; and so, of course, ends the history of that once famous establishment, " The *Gower-street* University of London."

The above-mentioned " Address of the Senate to the Council," we looked through with much curiosity—a feeling which its perusal scarcely served to allay. The authors of it must be allowed much credit for the skilful manner of its composition; it has been successful, too, it seems, in making converts. Lord Brougham himself said that *he* was converted by it; but for our part, its principal effect upon us was to augment rather than to allay surprise. A flood of new light, we found, had burst upon the Senate; the mist was taken from their eyes; they now saw what they could never see before; the whole system, as now laid down by government, they find to be the best that could possibly be devised; a central body conferring degrees under the crown is a thousand times preferable to having the show of such a power entrusted to their own exclusive possession; the degrees themselves will be far more valuable, and the Professors will be all the better for having an independent examining body to deal with their pupils. In fine, the burthen of their song is congratulatory; they now discern the advantage of being subordinate to a body under the control of government; and seeing all this, they cannot but wish the Council and the proprietors joy that they did not succeed in that plan of exclusiveness and monopoly which they so long and so ardently yearned for.

The sum of all this would be very amusing and satisfactory, were it not somewhat marred with a strange attempt to prove that there is no inconsistency whatever in the present proceeding; that neither they, the Senate, nor even the body of proprietors themselves, in taking what is now offered them, compromise any principle formerly advocated: the amount of which is, that they hold the same doctrines now that ever they did. How curious, then, that they have never had the faculty of speaking out their mind intelligibly before! But it is too absurd to waste a word of argument with such wayward opponents,—opponents, besides, they can hardly be considered now, when they have just adopted all the opinions we have been endeavouring to impress upon them for some years past. One only question we will put to them ere we lay aside our pen: if they always thought as they do now, what, in the name of wonder, could have seduced them into the expenditure of hundreds and hundreds of pounds—which of late they could ill spare—to fee lawyers and functionaries usually employed in the procuring of charters? What was the burthen of all Dr. Lushington's arguments last year

before the Privy Council, when the self-styled University sought to make good its claims to certain privileges, in the teeth of all the combined colleges and schools of England?

LIBERAL ENCOURAGEMENT OF MEDICAL REFORM.

It would appear from sundry announcements, bearing the signature "John Epps, M.D., Hon. Sec.,", that there exists in London, or elsewhere, a medical reform association—so called.

We express ourselves thus doubtingly about the matter, because no one of whom we have inquired every heard of the society, or knows any thing about it. However, about a year ago, an advertisement was inserted in the *liberal* journals, offering 100l. for the best essay on medical reform; competitors being directed to forward their papers by a particular day, after which the "Committee" were to enter upon their duty of awarding the premium to the successful essayist. The time accordingly arrived, and all—that is, all who had sent papers—were curious to know the result. Time, however, passed on, and no announcement of the proceedings of the Committee was made. At last (about a fortnight ago) there was given to the world, through the same respectable channel, a notice from "John Epps, M.D., Hon. Sec.," informing all whom it might concern, that the Committee had decided that none of the essays were good enough to deserve the reward. The hundred pounds is therefore to remain—where it was! The names of the committee of humbug who have thus juggled the competitors have not been published, but the Treasurer is said to be no other than Joseph Hume, M.P.; in which case the prize-money (if such there really be), is obviously in very safe keeping.

KING'S COLLEGE.

CHAIR OF MATERIA MEDICA.

About three weeks ago we stated that Dr. Paris had been duly appointed to the chair of Materia Medica in King's College, but that Dr. Webster, who was lecturing for his friend, Dr. Bisset Hawkins, was for the present to continue his duties. On the same day that this information was given to our readers, the Lancet very wisely announced that Dr. Paris had declined the chair, and intimated that Dr. Webster was to be the new Professor. But having become aware of his mistake, by what appeared in the Gazette, he proceeds last week to correct it accordingly; instead, however, of limiting himself to the simple truth, he instinctively *embellishes*, and adds as facts certain inferences of his own, deduced from our account of the matter. Thus, speaking of King's College, he says, "Dr. Webster has been used very ill at this institution. We are authorized [*qu.* by whom?] to state that he has received sudden notice to quit the chair," &c. Now we *are authorized by* Dr. Webster *to state*, not only that such announcement was made without his authority, but that there is not one syllable of truth in it. He has received no "notice to quit," suddenly or otherwise, but is to lecture till the end of January, so as to complete the first course of Lectures, just as originally proposed. He did not offer himself as a candidate, in opposition to Dr. Paris, and has nothing whatever, in the shape of being "ill used," with which to charge King's College. So much for the Editor of the Lancet being "*authorized!*"

DEATH FROM QUACK MEDICINE.

MORISON'S PILLS.

Another exposure has been made of the dangerous consequences of taking those pills. Were it not for the occasional inquests which are held on the bodies of per-

sons who are tempted to use them, the public generally would know little or nothing of their deleterious effects. Probably many a death from the same cause occurs in private families—even under the eye of the regular practitioner, called in when too late—but the matter is hushed up from a dread of publicity. There is, however, no other way of ridding the world of quackery than by exposing its criminal ignorance and wickedness. We would suggest that it is the duty of practitioners to publish every case of the kind that falls in their way, whether publicly investigated or not. The names of the victims need not be divulged, yet the cases may be perfectly authenticated.

On Friday evening, last week, an inquest was held at the Sovereign, Munster-street, Regent's-park, before Mr. Stirling, on view of the body of Mrs. Sarah Porter, aged 35, of Clarence-gardens, Regent's-park.

The first witness was Dr. J. Johnson, who deposed that he attended the *post-mortem* examination of the body, and was of opinion that death was occasioned by inflammation of the intestines, brought on by some irritant substance taken internally.

Mr. Beale, surgeon, of Long-acre, deposed that he had attended the deceased several times. She was a very delicate woman. On the evening of the 20th inst. witness was requested to attend her. On his arrival he found that she was in a state of delirium, and incapable of articulation. On inquiry, witness ascertained that the deceased had taken several doses of "Morison's pills." She continued to get worse, being violently affected; on the 22d she became somewhat sensible, complaining of violent pains in the bowels; on the 23d all the symptoms became aggravated, and she died on the evening of the same day. Witness concurs in the opinion of Dr. Johnson, that the death of the deceased was caused by inflammation of the intestines, brought on by the administration of some violent medicine.

Sarah Paine, servant to the deceased, proved having purchased three separate boxes of "Morison's pills," at No. 43, Munster-street, which were taken by her mistress in doses of 14 and 16 at a time.

Other relatives of the deceased were examined, who stated that the deceased was advised to take the pills by a Mrs. Robinson, a neighbour; but she (deceased) becoming worse, they advised her not to take more.

The jury severely animadverted on the sale of the pills in question, and, after some discussion, returned a verdict, "That the deceased died from inflammation of the intestines, caused by taking Morison's pills."—*Times* (Nov. 28.)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, November 24, 1835.

HENRY EARLE, ESQ., F.R.S., PRESIDENT, IN THE CHAIR.

WE take this opportunity of laying before our readers an abstract of Mr. Perry's paper, to which we were only able to allude in our last report.

History of a remarkable Case of Varicose Aneurism, with Observations, by J. G. Perry, Esq. Surgeon to the Foundling Hospital, and to the St. Marylebone Infirmary.

The author begins by referring to M. Breschet's researches on the subject (Mem. de l'Ac. de Med. iii.) and to Dr. W. Hunter and others, who seem to think that a communication by an artery and adjacent vein can only take place in consequence of a penetrating wound. Veins are not readily affected by the ulcerative process even of all the parts around them; and it would naturally seem unlikely that an opening could be made in their coats by the ordinary causes of absorption. Aneurisms have absorbed all the structures in their vicinity excepting their accompanying veins; but the case here related will show that the general law (if it be one) is not without some exception.

Jon. Allum, æt. 47, had been a dragoon early in life, but left the army in 1819, discharged for ill health. The only accident he could recollect having happened him was his having once been knocked down along with his horse by the fall of a heavy piece of timber. His left knee was hurt, and ever afterwards was weak and sometimes painful. In 1831 he first perceived a small swelling below the knee, but it gave him no pain, and he disregarded it. It increased in size slowly, but latterly was at times so painful as to oblige him to discontinue his labour, which was that of drawing a truck. The swelling had existed for two years, when his wife perceived a palpitation in the middle of the left thigh, resembling one of the heart to which he was also subject. It was, however, disregarded, but went on increasing simultaneously with the swelling below the knee.

On the 6th February, 1834, he applied

at the Infirmary for relief, and was admitted. An aneurism was then found to exist at the upper and inner side of the calf of the left leg, apparently occupying the lower end of the popliteal, or commencement of the posterior tibial artery. The pulsation in the thigh, along the course of the femoral artery and vein, could be distinctly *seen* as the patient lay in bed: it was about two inches below the crural arch: it was attended with a *purring* or *whizzing*, distinct from the beat of the artery, for the peculiar purr continued without intermission. Various opinions were given of the phenomenon by different observers: ligature was thought inexpedient, as the vessel was considered to be unsound even within the abdomen.

From some observations which he made, the author fancied he detected a communication between the artery and vein. The recumbent posture was enjoined, and a bandage from the foot to the groin, for the purpose of pressure, was tried, but discontinued in consequence of the uneasiness it occasioned. A sort of truss was found most likely to do good.

After nine months' residence in the hospital, he was permitted to go home, at his own urgent request. He was there visited, and the disease made no remarkable progress until September last (1835), when he applied for re-admission. In three days the tumor in the ham had increased to three or four times its former size, with an appearance of sloughing on its most prominent part. Operation was the only chance, and it was accordingly performed in the usual way. Upon opening the sheath of the vessels, the artery was found nearly as large as the abdominal aorta, and its coats so thin (and fragile also) as rather to resemble a vein than an artery. The ligature was accordingly very cautiously applied, with just sufficient tightness to stop the pulsation in the sac and lower part of the artery.

On the 5th day after the operation hæmorrhage suddenly took place from the wound, inducing syncope. This was temporarily remedied; but the patient sunk exhausted on the 6th day.

Dissection showed the left ventricle of the heart hypertrophied. The abdominal aorta was rather thin in its coats. The external iliac arteries (the left particularly) were singularly tortuous, and reflected on themselves in their passage to the crural arch. Immediately below the origin of the profunda the femoral artery appeared to have been affected with considerable aneurism; there was an opening observed in the sac from which the fatal hæmorrhage came.

At the point where a communication between the artery and vein had been suspected, an aneurismal sac was found, firmly ossified within, and which, by pressure, had formed an opening in the adjacent vein, into which the aneurism had burst. Below the aperture the vein was obliterated at a single point, but below that was again pervious. The aneurism at the ham was also examined, and a preparation made of all the diseased parts.

The author concludes with some remarks on the extreme infrequency of sloughing of the veins from pressure, or surrounding ulceration. He also observes, that the case just detailed confirms Breschet's remark, that the thinning of the arterial coats, and the dilated state of the vessel above the opening of communication, are consequences of the long duration of the varicose aneurism.

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

By M. Andral.

*** The portion of M. Andral's Lectures which treats of Diseases of the Nervous System, is in course of publication in Paris, with the approbation of the learned Professor. Should they prove of a nature to interest our readers, we shall give them in some of our ensuing numbers, stripped however of all redundant phraseology: meantime we subjoin the Introductory discourse, which contains some good general remarks upon the subject.

General Observations—Sources of Difficulty in the study — Insufficiency of our means of Investigation — Imperfect assistance derived from Post-mortem Examinations — Idiosyncrasy and particular Conditions of the Nervous System — Effects of Imagination — Elucidations afforded by Comparative Anatomy—Plan of the Course.

The study of diseases of the nervous system is rendered difficult, owing to the multitude of facts which it is necessary to collect being scattered through various books and periodical publications. We have not as yet any work which has embraced all the diseases of this system considered as a whole; and the difficulty of the study is still further increased by the diversity of the opinions which have been deduced by each observer from the facts which he has witnessed, and between which it is necessary for us to make our choice. In devoting ourselves to this laborious study we are led to the conclusion, that the science is, in truth, still in a state altogether initiatory: it as yet falls

far short of that which relates to the diseases of the other systems.

I shall enter upon some details which will make you better appreciate the truth of this remark. In every disease we have necessarily to study the causes, the symptoms, the anatomical lesions (of which the symptoms are often the effect), and, lastly, the treatment. But when we turn our attention to the affections of the nervous system, we find various circumstances which make the study of their causes, their symptoms, their anatomical characters, and their treatment, present difficulties which are not met with in the diseases of other parts. Let us pass in review those different orders of difficulties, and first let us take the causes.

Here, as in all other diseases, the causes are to be found, 1st, in the external world; 2ndly, in the reciprocal action of the organs upon each other; 3rdly, in the nature of the functions of the diseased organ, and in their modes of performance.

The nervous system is not influenced in a very remarkable manner by external agents; there is no comparison, for instance, in this respect between it and the systems of respiration, digestion, &c.

The second order of causes exhibits a very powerful influence on the production of diseases of the nervous system. Every organ which is deranged in its mode of action—reacts upon the nerves. There can be no disease in which they are not of some account, sometimes in a secondary manner, but often to such extent as to deserve to be placed in the first rank. It is thus that certain primary conditions of the liver, the lungs, or the intestines, in their progress become accompanied by nervous affections, which give them a specific character.

With regard to the third order of causes, every organ derives a source of disease from the nature and mode of action of its functions; but to the nervous system belong the intellectual and moral phenomena which constitute a cause of numerous diseases proper to this system; and as these phenomena of intellect and morals are not accomplished in the same manner in different individuals, but are modified by the diversities of position in society, by different ages, by professions, by religious opinions, &c. it follows that we have corresponding differences in the aspect of the same disease. For example, in private and hospital practice we observe that individuals have the nervous system affected in a different manner. And as the ideas of each cycle have their particular impress, (religion, for example, which was carried to excess in the middle ages, has given place by degrees to ideas of a different kind,) we ought not to be astonished that certain maladies which were developed under the influence of fanatical excitement, are no longer to be met with in our day, such as the epidemics of St. Vitus's dance, religious ecstacy, &c.; whilst, on the other hand, there are some now prevalent which were not formerly observed.

Next, of the symptoms; and here we encounter serious difficulties, which, for the most part, do not present themselves in the diseases of other organs:—1st, There are some which depend on the insufficiency of our means of investigation. Our senses cannot be made use of here in the same manner as in the diseases of the thorax or abdomen, for example, the diagnosis of which has attained so great a degree of precision. For the most part we only recognize diseases of the nervous system by induction; the difficulty is therefore immense, as compared to the others. 2nd. Other difficulties originate in the effect of premature theories which have embarrassed the study of these maladies. The theory which would attribute all the affections of this system to an increase or diminution of excitability, is inadmissible. There is something more than this, for assuredly numerous and varied disorders may be the result of a simple perversion or aberration of action. 3rd. Different lesions may give rise to similar symptoms: thus the same phenomena will often be manifested in two individuals, the one attacked with congestion, the other with anemia of the brain; so that under such circumstances it is less by the symptoms themselves than by the previous history that a diagnosis can be established. On the other hand there are lesions identical in their nature which may produce different symptoms, and this may depend on difference of situation, the gradual or rapid formation of the lesion, its extent, &c.: thus the derangement varies according as the cerebellum or brain is affected.

The brain ought to be considered as a complex organ formed by an aggregation of parts having different functions; but the localizations which have been attempted to be made are premature. We do not know the precise seats of the different faculties: these are questions for the future: and even were this diversity of organs to be admitted, it must ever be kept in mind that there is a connecting bond which establishes an unity in the vital principle. As to the rest, all these difficulties may be appreciated and subjected to certain laws; but there is one which is unknown, and which must not be left out in the account,—for it is a matter of fact: I speak of *idiosyncrasy*, in virtue of which the same action sometimes produces in two individuals phenomena so very different. Now

this idiosyncrasy plays an important part, particularly in the diseases of the nervous system.

Nor is this all. The sympathetic reactions become the source of prodigious difficulty, in the study to which I now allude. Sometimes we do not know whether the symptoms which we observe have their starting point in the nervous system, or some other organ; as in the cerebral fever of infants, &c. The symptoms of the diseases of the nervous centres present remarkable differences according to the period of life; so that two accurate observers, one placed in an hospital for adults, and another in an hospital for children, would give totally different descriptions of disease, and yet their facts might be perfectly accurate,—only they would have observed individuals of different ages. Here, then, are difficulties of the greatest magnitude, and which are not met with in the diseases of other parts.

But to continue. When we have determined the nature and seat of a disease, we have not yet done all; we must next inquire into the anatomical lesions. Undoubtedly pathological anatomy has within the last few years discovered some alterations of the nervous centres which were not known to us before. Thus *softening*, scarcely admitted by Morgagni, has been the object of valuable researches by Lallemand, Rostan, and others.

The cases in which some appreciable change is discovered by the anatomist after death are the most common with respect to other organs, while it is just the reverse with the nervous system: the cases wherein lesions are discovered are by much the most rare. This fact would appear a paradox if we only directed attention to the three or four diseases of the nervous system observed in hospitals; but it is by hundreds that we count nervous affections, and to cite only the principal of the neuroses implicating the powers of motion, sensibility, intellect, &c. where, let me ask, are situated the lesions in them? either we find none, or those we do find have no relation to the phenomena previously observed. Are we therefore to say that none exist? We *see* nothing certainly, but it is probable that there is organic lesion nevertheless, because there is lesion of action. However, we are not yet at the end of our anatomical discoveries: let us wait in hope. It has been said of late years that disturbances of the intellect are connected with alterations of the grey cortical substance. The fact has been disputed, but may, perhaps, at a future period be definitively ascertained. There are other researches, however, besides those which belong to the knife. Thus certain disturbances may be connected with changes in chemical composition resulting from various circumstances. Accordingly, of late it has been found that from infancy to old age, there is a progressive diminution of the watery elements, and increase of the albuminous. Phosphorus is at its maximum quantity in adults, &c.;—but these, again, are questions for future investigation, for the facts are not yet perfectly established.

We have thus seen the difficulties connected with the study of the causes, the symptoms, and the anatomical characters: there are others which are furnished by the treatment. In all the other organs, when we observe signs of irritation or excitement, we infer, as a necessary consequence, that there is a phlogosis, requiring the use of antiphlogistics, but with respect to the nervous system it is in many cases quite otherwise. Thus symptoms of excitement may exist; you bleed, and the symptoms become aggravated in proportion as the individual is reduced: now these morbid conditions which depletions increase, may exist along with other diseases which would require the abstraction of blood, but which is here contra-indicated; for the state of the brain after the bleeding would be more formidable than an inflammation of the lungs, of the intestines, or even of the peritoneum. And by a remarkable coincidence, this state, which is so intolerant of bleeding, is sometimes produced by the loss of too large quantities of blood: under the influence of preparations of iron and antispasmodic remedies it disappears, and harmony is restored by those means in cases where depletions would certainly augment the disturbance.

There yet are other means from which we can derive prodigious assistance; namely, those which act on the imagination. Certain diseases are produced in those subjected to the influence of strong passion, or religious enthusiasm;—and such maladies may be cured by means analogous to those by which they have been produced. It may be remarked, too, that it is not simply nervous affections, but various other diseases, which have a tendency to become organic, which admit of being thus removed. Thus it is the effects produced by a lively faith in the *baquet* of Mesmer, and the various trickeries of magnetism, as well as the infinitessimal fractions of homœopathy, all of which have a great effect on the imagination, are among the sources whence great assistance has been derived.

It has been said that in proportion as the sciences have advanced they have always become associated at a certain elevation; and, accordingly, when we study the maladies of the nervous system, the possibility of having light thrown upon the subject by other branches of knowledge becomes apparent to us. Dissections con-

nected with this investigation require to be of the finest and most minute description: for instance, there are certain diseases of the cerebellum which produce blindness in infants; and the point to be investigated in such cases becomes—what is the relation between this part and the optic nerves? There is a connexion, in truth, with the tubercula quadrigemina by the processus cerebelli ad testes, from whence the second pair of nerves derives some of its roots. In certain cases the power of motion has been seen to continue in the lower extremities notwithstanding that the spinal marrow was almost entirely interrupted, a small shred of the slenderest kind being the only medium of communication between the upper and lower portions; or even there may have been nothing but a little fluid interposed, and then it has been a question how it came to pass that the functions were not entirely suspended? Comparative anatomy has stepped in to our assistance, and has shown us that in those cases where the spinal cord is no longer an organ of sensation, it has but a very small volume. It has further shewn that in certain fishes, the nerves, though separated from the cord by a liquid, are nevertheless fitted for transmitting the power of motion. To these beautiful results experimental physiology has added its facts, and has rendered immense service to pathology. It is thus that certain kinds of paralysis of the face, where sensation remains entire, and *vice versâ*, have been so well explained since the discoveries of Sir Charles Bell; and that M. Magendie in particular has placed it beyond a doubt that lesions of the posterior portions of the spinal marrow give rise to disordered states of sensation, and those of the anterior portions to disturbance of the powers of motion. There are cases in which an individual has been known to become blind, and deaf, and to lose the sense of smell, without any alteration in the corresponding organs—the eye, the ear, and nostrils, or in the optic, acoustic, or olfactory nerves; and such facts were placed among the number of those on which pathological anatomy had thrown no light. However, it has been very recently proved that in man the fifth pair is accessory to these very functions—sight, smell, taste; while in certain species of animals, comparative anatomy has demonstrated this same pair to be the principal nerve of those senses. Guided by this knowledge we have been led to inquire whether in certain cases of deprivation of sight, hearing, &c. there were not some lesion of the fifth pair, and sometimes such lesion has been found there, and there alone.

But pathology returns what it borrows: if it receives the light of the sciences above mentioned, it becomes in its turn a fertile source on which the anatomist and physiologist may draw for aid in elucidating many points. It is therefore not without reason that it has been said, that the sciences, in proportion as they advance, tend at a certain elevation to the improvement of each other.

The order I shall follow on the present occasion is the same I usually adopt: we shall consider—

1st, The diseases of the nervous centres;
2nd, Those of the cords;
3rd, Those of the great sympathetic.

The other subdivisions will also be the same, and will comprise—

Lesions of circulation.
—— of certain secretions (cerebral œdema.)
—— of nutrition (*a.* augmented; *b.* diminished; *c.* perverted.)
—— of inervation; that is to say, of functions (intelligence, sensation, movement.)
—— of inervation of the organic functions (digestion, generation, secretion.)
—— of the forces which direct and regulate the laws of organization, and which constitute the vital powers (the sthenic, asthenic, and ataxic conditions.)

In this course we shall have to study facts, some of which are demonstrated, and some which, though not demonstrated, are yet probable: we shall find others which are reputed false and inaccurate, but which we shall not reject without investigation; for certain facts which have been reputed false at first, have after a time been established, while the favourite theories which had led to their rejection, have themselves been overturned.

We shall also consider certain theories, because theories connect facts together, and on that account become interesting, however unstable and short-lived in themselves. We shall be careful in rejecting hypotheses too, because what was hypothetical yesterday has sometimes become matter of demonstration to-day.

There are some questions which I shall content myself with merely stating: choosing the middle course between that exaggerated scepticism which annihilates every thing, and a too easy credulity which inclines to believe every thing: the kind of doubt which I recommend is not scepticism, but is one essential to science, and to those who cultivate it.

——

LECTURES

ON

SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

Auscultatory Symptoms—Crepitations, or Moist Sounds, that attend the Act of Breathing—Large and Small Crepitations—The Distinction obvious and useful in its main Characteristics; uncertain and useless in its lesser degrees—Crepitations the most frequent of all Auscultatory Signs—What they can, and what they cannot, teach—How they need other and more general Symptoms to interpret their meaning—Acute Inflammation of the larger Bronchi; of the smaller—That Inflammation of the Bronchi which accompanies Diseases of the Heart—That which simulates Phthisis—That which is called Peripneumonia Notha—How much in each can be inferred from the kind and extent of the Crepitations—The Crepitation characteristic of Pneumonia.

THE sounds produced by the meeting and mingling of air with fluid in the bronchial tubes during the act of respiration, I have called Crepitations; and of Crepitations I have made one distinction only, large and small.

Between the largest of the large and the smallest of the small there are many intermediate degrees; and some of these may perhaps seem to deserve a name. But, for my own part, I always have had a sort of nervous horror of multiplying names, especially where things are essentially the same, and differ only in being greater or less; therefore I cannot bring myself to invent several names to designate different degrees in the present instance.

But though the extremes are far apart, yet in the midway large and small Crepitation will so nearly meet, that there must often be a doubt which is which; and what one man calls large, another will call small. Language, however, will afford no remedy where the difficulty is in the thing itself. You can only accurately distinguish things when they are some way apart, and not when they lie close upon the confines of each other. You can distinguish between light and darkness, but you cannot put a mark upon the boundary between day and night.

Large Crepitation arises from air meeting and mingling with fluid in the larger bronchi; small Crepitation from the same conditions in the smaller bronchi and the vesicles of the lungs. This is an important distinction, and I desire to make much of it;—important, however, in its main and prominent characteristics, but useless if it be refined into many degrees.

Without wishing to enter upon a criticism of nomenclature, I would further remark that, in giving names to auscultatory signs, we should take especial care that the names themselves do not imply any thing that is erroneous; and that they do not go beyond the truth, in pretending to designate that which they *certainly cannot* designate.

What I call "large Crepitation" is called by most French writers "râle muqueux," and by most English writers "mucous rattle." Call it râle, or rattle, or Crepitation, or what you will; but pray do not add "mucous" to it by way of specific difference; for this term must always seem to imply that the sound is produced by air passing through *mucus;* whereas it is produced equally by air passing through mucus, or pus, or blood, or any fluid whatever. Besides, it is beyond the truth to say that the *quality* of the fluid through which the air passes *can* be distinguished by the quality of the sound that results. The sound will indicate the *situation* and quantity of the fluid, and no more.

Therefore, by whatever name you choose to designate the moist sounds arising from the bronchial passages during respiration, be it Crepitation, râle, or rattle, you cannot distinguish it by any other epithets of more precise meaning than "large or small," without implying more than you intend, and that, too, something erroneous, or something beyond the truth.

Crepitation, or the sound which shows that the moisture of the bronchial passages is in excess, is the commonest of all auscultatory signs. Go round this hospital, and, out of the five hundred and more patients which it contains, you will probably find Crepitation in above fifty. And in all these it arises immediately from one and the same condition—viz. from excess of fluid in the bronchial tubes or vesicular structure.

But the fifty patients cannot, in any just sense, be said to have the same disease, because a single pathological condition is the same in all. Neither, on that account, will all be found to demand the same treatment.

I speak of disease and treatment in the largest and most comprehensive sense.

Now the fifty patients, who have all Crepitation of their lungs, are not suffering alike in *other respects.* And *these other* respects in which they differ, include the

great characteristics of their diseases, and the special indications of their treatment.

At present I am speaking only of *direct symptoms*, immediately referable to the part affected. When I come hereafter to speak of *indirect* symptoms, or those which, originating in one part, declare themselves through the medium of another; and of general or constitutional symptoms, the signs of the pulse, and of febrile and nervous affections in their various kinds and degrees; then I will endeavour to show that many diseases, apparently local, have a much larger range throughout the body, and that the treatment which is to compass their cure must be alike comprehensive in its influence.

Learn, however, all that is capable of being known concerning the *mere* part. Let the patient tell you how it feels amiss, and ascertain for yourselves how it acts amiss; and if it be a part within reach of the sight, the hearing, or the touch, make out what changes of structure it has undergone. Still its sensations, its functions, and its structure, will only half inform you what are the essentials of the disease it suffers.

Remember, there is a pathology of diseases *beyond* the part, as well as a pathology of diseases *within* the part; and that the things beyond it are really and practically the great interpreters of the things within it.

Remember, there is a great vascular system and a great nervous system, and that these, according to the manner in which they are actuated, assign a character to the local disease, and determine its treatment accordingly. Concerning the disease, they tell us what is its force of action, and what its rate of progress; and, concerning its treatment, they teach us to choose the remedies, and so to regulate their impression as to counteract this force of action, and to keep pace with this rate of progress.

Bearing these considerations in mind, you will be able to comprehend what I mean by saying, that the many patients in this hospital who have Crepitation as a common auscultatory sign, and redundant fluid in the bronchi or vesicles as a common pathological condition, may nevertheless have different diseases. And, still bearing them in mind, you will now be able to follow me as I run over a few prominent distinctions.

Among the many who have this auscultatory sign, in some it has endured for weeks or for months, and in some it has sprung up since yesterday. In some it is accompanied by much fever and great vascular action, and life itself seems already in peril, although it has existed but for a few days.

In some it is accompanied by less fever and less vascular action, and there is yet no peril of life, although it has existed for many weeks.

This crepitation is present in Rheums and Catarrhs, and Chronic Coughs, which cleave to old people, from the end of autumn to the beginning of spring, with little or no fever.

And it is seldom absent in Chronic Diseases of the Heart; and here it is found sometimes with and sometimes without fever, or any signs of inflammation; as if the bronchial surface had the power of *simply* increasing its secretions for the relief of a burdened and baffled circulation through the lungs.

Crepitation also is a frequent accompaniment of pulmonary hæmoptysis, with or without fever.

Now, while the great constitutional symptoms are our paramount guides to the knowledge and treatment of the disease as a whole, it is to *this Crepitation* that we are to look, in each particular case, for the knowledge of what the disease is in the lungs; its exact seat, its extent, and the stage of its progress.

The case is one, perhaps, in which there is much fever and great vascular action; while cough and dyspnœa, and some expectoration, denote the lungs to be the part upon which the inflammation has specially fallen.

We auscult, and discover Crepitation: and the Crepitation has one main and prominent characteristic; that it is large. It is *large*, and *large* exclusively; while through it, wherever it is heard, the respiratory murmur is also heard in every part of the lungs.

Such auscultatory signs denote the mingling of air with the matter of morbid secretion in the larger bronchial tubes, and in them exclusively; the lesser tubes and the vesicular structure of the lungs, the seat of the respiratory murmur, being entirely free.

But the much fever, and the great vascular action, declare this condition of the bronchi to be the work of the severest inflammation, and of inflammation that is still going on. Yet, while auscultation continues to show that such is exclusively the seat and limit of the inflammation, severe as it is, we are warranted in expecting a favourable result; provided always that we pursue a just treatment. For even the acutest inflammation of the larger bronchi is unapt to extend itself to other textures, or involve the structure of the lungs beyond those bronchi themselves.

But the case is one, perhaps, in which

there are the same constitutional symptoms bespeaking the disease to be inflammation, and the same local symptoms, fixing that inflammation upon the lungs. But withal, the Crepitation heard during breathing is *small*, and *small* exclusively; and this small Crepitation, wherever it is found, has entirely obliterated the respiratory murmur.

Such auscultatory signs denote the mingling of air with the matter of morbid secretion in the lesser bronchial tubes, or the vesicles of the lungs.

In the former case, the disease was acute inflammation, and it is no more than acute inflammation in this. We have the same means of subduing inflammation in this which we had in that, and the same plain indications to direct our treatment; and the disease, *in its own nature*, is as amenable to remedies *here* as it was there. Yet are we *not* warranted in forming the same expectation of a favourable result. Because inflammation of the lesser bronchi, unlike that of the larger, is ever ready to pass beyond them to other textures, and to involve the whole structure of the lungs.

Where you have small Crepitation one day, you may find that it has entirely ceased the next; and ceased, not to be replaced by the respiratory murmur, but by absolute dulness and total obliteration of sound.

And what is implied by this rapid change from small Crepitation to total obliteration of sound? Even this; that the bronchial ramifications and vesicular structure are so pressed upon, from within and from without, by the effused products of inflammation, by serum, or lymph, or pus, or blood, or a mixture of all, that air cannot enter, and the lung has become solid at that part, and may possibly have undergone irreparable disorganization.

Let it not, then, be esteemed a small thing, that, upon rational grounds, and by tokens which we can justify and explain, we are able to arrive at this diagnosis; that, in the severest inflammation of such an organ as the lungs, we can mark the cases which are within the probability of a perfect cure, and those which are beset with the most perilous hazards.

To distinguish between inflammation of the larger bronchi and inflammation of the smaller, or of the vesicular structure, is still important in all its degrees, and whether it be chronic or acute; and auscultation will always enable us to do so.

Chronic inflammation of the larger bronchi, after months and years, is still reluctant to extend itself to other structures; whereas, chronic inflammation of the lesser bronchi is alway ready to spread beyond its original seat.

The most frequent instances that I meet with, of inflammation, slight in degree and chronic in duration, affecting the lesser bronchial tubes and producing effusion into them, are those in which it accompanies chronic disease or disorganization of the heart. It is evidenced by small Crepitation proceeding from a considerable space at the lower part of one or both lungs, and often continuing to be heard for months and months together. Thus, even for months and months, the lung may remain quite pervious, but crepitating. Yet there is no security, in the meantime, that what is pervious and crepitating to-day, may not be absolutely impervious and dull to-morrow. In point of fact, I have known, by the test of auscultation, nearly a whole lung become condensed and solid in the course of a single night, when there has been nothing to give warning of such a catastrophe.

Indeed, in the dissection of those who die of diseased hearts, we are accustomed to find the lungs generally loaded with serous and sanguineous effusions, while some portions of them are solid and impervious, and sink in water.

But chronic inflammation of the larger bronchi, after months or years, is still (I have said) reluctant to extend itself to other structures. After months, or years, auscultation still finds it in its original seat; the air bubbling through a thickish, copious, puriform fluid, and producing the truest form of large Crepitation.

There is a form of Chronic Bronchitis, in which all the conceivable signs of Phthisis are present except the auscultatory: emaciation, hectic fever, cough, and a copious thick yellow globular expectoration. Yet the chest sounds well every where upon percussion, and the auscultatory sounds are *purely bronchial*, and nothing more, and proceeding from the bronchi in their first divisions, and not beyond them; large, not small Crepitation; but large Crepitation widely diffused, and permitting the respiratory murmur to be heard every where through it.

Here the *larger* bronchi alone are inflamed, and filled with the matter of morbid secretion, while the lesser and the vesicular structure are free. There is, moreover, no cavity.

It would be beyond the power of the most sagacious physician upon earth, *without the help of Auscultation*, to distinguish this case from a case of phthisis; but by *such help* we not only determine this disease, which is so like phthisis, to be no phthisis at all, but we pronounce it curable—that is, curable in its nature, although from circumstances not always cured.

Cases of this kind—cases of chronic bronchitis, in which all the conceivable

signs of phthisis are present except those which indicate vomicæ—are not common. I see a few of them in the course of the year.

They are more frequent, to my experience, in the hospital, than in private practice. The disease usually begins in a catarrh, which, from neglect or unavoidable exposure, is aggravated into a similitude of phthisis. Under this similitude it may endure even for a year or two, and becomes difficult of cure in proportion to its continuance.

But, where there is Crepitation, it need not necessarily be of one kind only. In the same patient you may hear at one part of the lungs a Crepitation like the tracheal rattle of the dying; at another, like the bursting of large bubbles on the surface of water; at another, like the crackling of salt thrown upon hot embers.

There is a disease which was first called by Sydenham *Peripneumonia Notha*, and which is still known by that name. It is, in fact, a diffused inflammation of the bronchial tubes, chiefly incident to old people. One of its peculiarities consists in the enormous secretion that is poured forth from the mucous surface; and another which I have remarked is, that the inflammatory symptoms often still remain, nay, often continue to increase, after the secretion is freely established. This latter peculiarity (if auscultation informs me aright) is derived from the fact, that inflammation does not arise at once and simultaneously upon the whole surface which it is destined to pervade, but travels over it progressively; so that various portions of the same continuous surface are in different stages of inflammation at the same time. How possible this is, every one knows, who has watched erysipelas travelling over the whole body.

Cases of Peripneumonia Notha I recommend to you as special studies for auscultation: here you will often find, in the same patient, every modification of those sounds which are produced by the matter of morbid secretion mingling with air in the bronchial ramifications of every size, from the largest to the least.

The common opinion is, that old people die of Peripneumonia Notha simply because they have not power to bring up the large accumulation of phlegm; implying, that the whole disease is limited to the first divisions of the bronchi, and that if they were freed from obstruction, there is nothing beyond them, nothing in the condition of the lungs elsewhere, capable of producing death. Doubtless, it is quite possible that accumulated secretion of any kind in this situation may be the whole and sole cause of death: it may suffocate by its very quantity. But this I know that since I have had auscultation to help my inquiries, I have never seen any one perish of Peripneumonia Notha, in whom there was not elsewhere within the lungs enough to claim a large share in producing his death.

But I find myself speaking of Auscultation too much in detail for the purpose I have in view. In these lectures I would rather wish to give you such a notion of the general bearings of this and that subject, as will help you to follow it up for yourselves in the wards of the hospital. *Here* I am not so much striving to teach, as I am encouraging you to learn.

There is a Crepitation which consists of the *smallest* conceivable cracking—a noise like the crackling of salt thrown upon burning coals. This is regarded as the characteristic Crepitation of Pneumonia, because wherever it exists, it is always for a short period only; and it is quickly followed either by the return of the natural respiratory murmur, or by the absence of all sound whatever. In the one case the passage of air through the vesicular structure of the lung has again become free, and a resolution of the disease has taken place; in the other case the passage of air is altogether precluded, and the disease has passed into its next stage, and has condensed the lung.

There is a doubt in *what* manner this particular sound is produced, and *where*. Some conceive it to proceed from the structure of the lung exterior to the bronchi or vesicles, and to result from the tearing of parts asunder that have been united by effused lymph. It may be so; but the fact would be extremely difficult to prove. To my ear the sound is the same in kind with those which I have described by the generic term Crepitation. Of these it is the smallest in degree, and probably proceeds from the same continuous surface, from the extreme vesicles and air-cells of the lungs; and is probably formed in the same manner, by the mingling of air with the morbid secretion which it finds there. This little crackling sound (so well known to those whose experience has taught them to appreciate auscultation in its practical use)—this little crackling sound, reaching the ear from a limited and circumscribed space within the chest, marks the commencement of pneumonia. It is a *direct symptom*, having immediate reference to the structure of the part. And if we consider what the part is, and what the disease—the part the lungs, and the disease inflammation—we cannot too highly value this single symptom (simple and mean as it may seem), which gives the earliest and surest

intimation that such a disease has begun as tends to disorganization and the inevitable loss of life, unless quickly arrested by its counteracting remedy.

Further, auscultation, having detected inflammation of the lungs at the point where it begins, still follows it as it spreads; and it follows not merely its progress, but its processes.

The Crepitus commencing at a small space, and gradually reaching farther and farther, gives notice of inflammation gradually passing from lobule to lobule, and effusing lymph into their vesicles as it spreads.

Then the crepitus becoming fainter and fainter, but not replaced by the respiratory murmur; and the spaces in which it was first heard becoming dull, and larger and larger spaces becoming dull in succession, until not a sound of respiration, either healthy or unhealthy, proceeds from (perhaps) half the chest; these striking phenomena give notice how the vesicular structure of a whole lung is progressively obliterated by the continually effused lymph and morbid products of the still unarrested inflammation.

Thus far the intimations of the ear keep pace with the progress and processes of an acute attack of pneumonia. Auscultation pronounces the permeable lung converted into a solid mass, and admitting no air, save what may just enter and immediately return from a bronchus or two which still remain pervious. Beyond this point auscultation cannot go. But the disease may go further.

This is a painful period of suspense in every case of pneumonia, when a whole lung, or a large part of it, has ceased to admit air, and the patient still survives.

The disease may have gone further than auscultation can follow it. Auscultation only discovers that the lung does not admit air; that it has become solid from having been permeable. But its texture may be softened; its cohesion destroyed; and it may be reduced to a state of pulp and rottenness, which is irreparable.

If its texture be *not* thus disorganized, it is yet capable of reparation; and then, the inflammation having ceased, Auscultation beautifully takes up its part again, and gives the first notice of reparation, as it gave the first notice of disease. Crepitation again begins to be heard where there was no sound. Soon it becomes more extensive, and some vesicular breathing is mixed with it; and the respiratory murmur and the Crepitation seem (as if) contending with each other for the mastery, until the respiratory murmur is predominant, and then all is well.

And what is going on all the while within the structure of the lungs? Even this. The lymph within and around the pulmonary vesicles is gradually absorbed, and the air gradually finds admission within them. At first it is impeded by the extravasated fluid it meets with in its passage; but as the permeable texture of the lungs gets disentangled and set free, it glides through them unobstructed and alone, and with the genuine murmur of health.

REMARKS ON VACCINATION.

To the Editor of the Medical Gazette.

Sir,

Should you deem the following remarks worthy of a place in your valuable journal, I shall feel obliged by your giving them insertion.

The opinion generally prevalent that vaccination may be performed with impunity at all ages, has I believe been productive of unpleasant results in many instances, where from the too great confidence in the innocuous nature of vaccination, the causes of those results have greatly perplexed the practitioner.

My observation was first attracted to this subject from the loss sustained by three of my most intimate patients, in the death of their children, all of whom were vaccinated under six months, and who were subsequently attacked with pulmonary disease within ten days from the disappearance of the eruption, which not the most active antiphlogistic treatment was able to subdue. Another case having recently occurred in which pulmonary inflammation supervened upon vaccination without any apparent cause, has again brought the subject before my notice, and I now forward you a few particulars of the cure.

On the 19th of October, 1835, Miss C. aged six months, was vaccinated, being at the time in good health. The vaccination progressed regularly in two pustules on the left arm. On the right no pustules appeared. Up to the 11th of this month the child seemed to be going on favourably, when, on that day, she manifested uneasiness about the præcordial region, attended with considerable disturbance of the system. Her bowels were open, and her motions not deficient in bile. Free incision was made on the gums, though no appearance of dental irritation presented itself, she having cut the lower incisors with ease prior to the attack. Expectorants, combined with bloodletting and blistering, were resorted to without benefit, and the child gradually grew worse, notwithstanding this treatment was persisted in, by the concurrence of two eminent practitioners, until a short time of her death.

The post-mortem examination discovered large patches of inflammation in the upper and posterior portion of the left lung, with hepatization of considerable extent in the middle lobe on the right side. At each incision of the scalpel matter oozed out in such quantities as astonished others equally with myself, and which sufficiently proved the active nature of the inflammatory symptoms. The abdominal viscera were healthy. The liver large, but free from disease. The head was not examined.

The inspection of two children, who died under similar circumstances, some time ago, gave analogous results.

Three conclusions may be drawn from the aforesaid case, emanating from the following questions:—

First—How far the introduction of a virus, generally supposed innocuous, may be productive of such irritation in the system, as to produce in an organ previously predisposed, so much functional derangement as to occasion death?

Secondly—Is the vaccine lymph capable of arousing the dormant energies of a diseased organ into action, when introduced into the system by inoculation?

And, *Thirdly*—Does not the age of the child materially modify the deleterious effects of the virus in proportion as the child advances in life?

Some of your readers will probably favour me with their conclusions on the above questions. My opinion is, that vaccination may produce disease; and that that disease may attack an important organ, destroy its function, and consequently life; and that the strength and age of the patient in a great measure prevent [illegible] surmount the attack.

It is not with a view to discourage vaccination that I make these suggestions, for of the benefit to be derived from it I am too well aware, but rather to elicit further information respecting its indiscriminate employment in reference to its safe adoption.

I remain, yours respectfully,

AN INQUIRER.

[The name of the writer has been communicated to us: we must remind all correspondents that though *opinions* may be adduced anonymously, all statements of facts ought to have the authority of the writer's name.—ED. GAZ.]

PORTRAIT OF TIEDEMANN.

WE beg to recommend to the special notice of our readers the admirable likeness of Professor Tiedemann, just published by M. Schloss. The expression is faithfully preserved, and the whole performance (for we have also seen the original sketch from which the lithograph has been taken) is highly creditable to the artist.

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XI.

THE MUSK ANIMAL.

IN my last lecture, I mentioned that the order of Ruminants was divided into those that had horns, and those without them. Having examined all the officinal horned Ruminants, I proceed now to notice the only hornless one, namely, the

Moschus Moschiferus, or Musk Animal.

FIG. 59.

History.—This animal was first described by the Arabian authors; Aristotle, Pliny, Ælian, and Oppian, make no mention of it. We are indebted to the Greek physician, Ætius, for its introduction into medicine.

Etymology.—Some derive the word μοσχος—παρὰ τοῦ ἐκ τοῦ μέσου χεῖσθαι (*because it flows from the middle of the belly*); others from μαω, *I seek*, this substance being sought after; some from μοσχος, *a calf*, on account of the supposed resemblance between the two animals. None of these derivations, however, are satisfactory; and it is far more probable that the word is of Arabic origin.

Description.—Observe, in the first place, that the animal is destitute of horns, and, therefore, is not, as some have termed it, a deer. There are 32 teeth, namely, 8 incisors in the lower jaw; 2 canines in the upper jaw, and 24 molars. The most important character, in regard to the teeth, is the projection (in the male) of the canines (fig. 60, next page) outside the mouth, in the form of tusks; in the female, however, they are not met with. The *stylocerus moschatus* (fig. 61, next page) forms the connecting link between the deer and the musks; having the horns of the one, and the canine teeth of the other. The tail of the musk is very short; the feet with hoofs; the hair coarse, varying in colour, but on the body it is for the most part dark brown. In front of the prepuce of the male is found the well-known musk bag.

Cuvier says, no other species of Moschus possesses a musk sac; but the correctness of this remark is more than doubtful. Eschscholtz has described as a distinct species, an animal under the name of *Moschus Altaïcus*, distinguished from the *M. Moschiferus* by a white stripe on the fore part of the neck. Brandt, however, regards it merely as a variety, under the name of *M. Moschiferus Altaïcus*. Two other species have been said to yield musk, namely, the *M. Napu* (the *M. Javanicus* of Pallas), and the *M. Jasanicus* or *Kanchil*. Mr. Martin, surgeon, of Islington, tells me he some years ago, when at Java, dissected one of the Javanese musks, and found a musk sac in it. He has the skin of the animal now in his possession, stuffed.

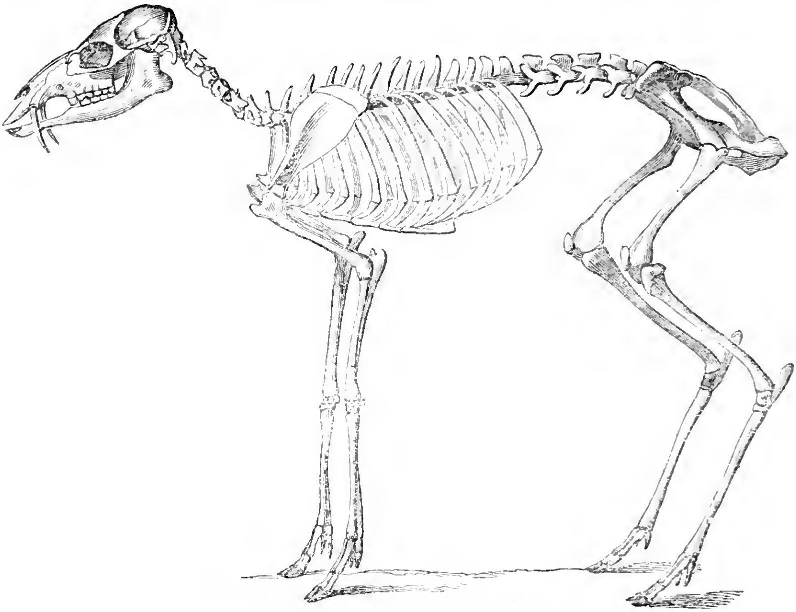

FIG. 60.—*Skeleton of the Moschus Moschiferus.*

FIG. 61.—*Stylocerus Moschatus.*

Anatomy of the musk sac.—When we examine the belly of the animal, we find in front of the preputial orifice (fig. 62, *i*, fig. 63, *d*), and behind the navel, a small aperture (fig. 62 and 63, *h*), leading into the cavity of the *musk sac.* This aperture (which I shall call the external musk aperture) is about half an inch from the umbilicus, and usually about a line or a line and a half from the preputial orifice. In this preparation, [shewing it] however, the distance from the latter is greater. The preputial orifice is somewhat more prominent, and has a number of longish hairs projecting from it, in the form of

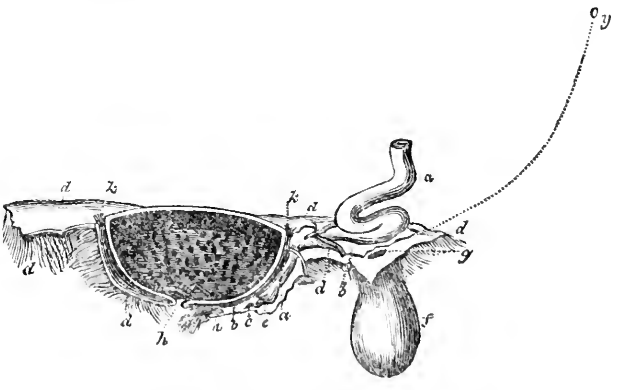

FIG. 62.—*Section of the Musk Sac in situ.*

h, Orifice of the musk sac.

a brush or hair pencil; whereas the external musk aperture is placed in a depression, and is smooth.

The musk sac is of an oval form, rather broader at the anterior than at the posterior part. It is flat and smooth above,

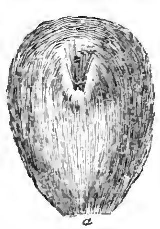

FIG. 64.

a, Penis cut off.

where it is in contact with the abdominal muscles, but convex below (supposing the animal standing.) Its breadth is from one inch and a quarter to one inch and three quarters; its length is from two to two and a half inches; its depth varies, being greatest anteriorly, where it is about half or three quarters of an inch.

I have already alluded to the external aperture in this sac. It is placed in the median line, but nearer the anterior than the posterior extremity of the sac. It is of a semilunar form, and its use is to allow of the evacuation of the musk. It leads into a small passage, which we may call the *musk canal*, the length of which is not more than a line and a half, and often not so much, the diameter being about a line. The internal orifice of this canal has a number of fine hairs placed around it, which easily coming off, are frequently found mixed with the musk of commerce.

I proceed, in the next place, to examine the structure of the musk sac. This organ is made of certain laminæ or coats, so disposed that some regard the musk sac as being formed by a fold of the skin of the animal, somewhat modified in its structure. Beginning with the most external, and proceeding inwards, they are as follows:

1. *The outer or hairy coat or skin.*—This is a continuation of the hide, and covers the convex portion of the sac — that is, it envelopes all that portion of it which is not turned towards the abdominal muscles. It is covered by a number of stiff but smooth hairs, which are so disposed as to form a kind of whorl or circular figure around the external musk orifice.

2. *Muscular coat.*—Beneath the skin we find a quantity of muscular fibre, which forms what we may term the muscular coat of the sac, consisting of two strata of fibres, between which, at the posterior part, is placed the penis. These fibres surround the sac in a circular form, as seen in fig. 65. Pallas states that they arise from the groin: anteriorly they unite with the panniculus carnosus. The same writer calls them the compressors and retractors of the follicle, and of the prepuce when the genital organ is thrust out. I have made out these fibres by soaking some of the most recent musk sacs of commerce for several days in water.

Pallas also describes and figures two muscular bands, which arise from the angle of the crura penis, and terminate at the glans. He calls them retractors of the penis.

On the inner surface of the muscular layers around the musk orifice, is a number of small oblong or roundish glands,

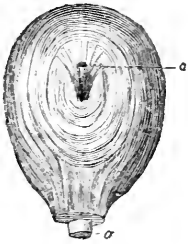

Fig. 65.

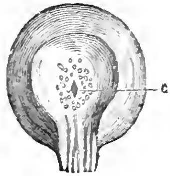

Fig. 66.

which Pallas has compared to the meibomian glands of the palpebræ. They are well shewn in this specimen. In fig. 66 is a drawing of them.

3. *Fibrous (?) coat: the most external of the proper coats of the sac.*—Beneath the muscular fibres is a lamina, which has (in the sacs of commerce) some resemblance in its firmness to the fibrous membranes; but its most remarkable character is the number of cells or depressions observed on its inner surface, and which are surrounded by ramifying folds. It is within these folds that the small vessels of the sac ramify; so that probably one use of them is that of a protection and covering to the blood-vessels. This coat is easily made out (as in the specimens before you) by soaking the musk sacs of commerce in water. It is continuous (through the musk orifice) with the corium.

4. *The second proper coat of the sac.*—Lining the fibrous (?) coat of the musk sac is a membrane, of a much softer and more delicate texture, and which generally has a shining mother-of-pearl-like appearance. It dips down into the depressions or cells of the fibrous (?) coat, and covers also the ramifying folds; so that on its internal surface it presents the same appearance of depressions and folds as the one just mentioned. It has been compared with the *rete mucosum* of the external skin.

5. *The epidermoid (?) coat: the third proper coat of the musk sac* has been compared to an epidermoid layer, though I candidly confess I do not see much analogy between them. It consists of two layers—an *outer* one, having usually a silvery white appearance—the *inner* one has a yellowish or reddish brown colour. These layers line the depressions or cells, already mentioned, of the foregoing coats, and cover the intermediate folds.

There is yet to be noticed a *glandular apparatus*, which secretes the musk. In each of the pits observed on the internal coat of the sac, there are found two or more irregular-shaped bodies, of a yellowish or reddish-brown colour. These bodies consist of a central brownish mass (supposed to be glandular), covered by a fine membrane.

Organs of generation.—Hitherto I have spoken of the genital organs in an incidental manner only; but it becomes necessary to say a few words on these parts, in consequence of their relation to the musk sac.

1. *Male genital organs.*—The *testicles* are oval, of the size of a walnut; the *vasa deferentia* are thin; the *vesiculæ seminales* small and oval; *Cowper's glands* are considerable; the *penis* is composed of one round *corpus cavernosum*, which terminates in a thin obtuse *glans*. The *urethra* is scarcely large enough to admit a straw,

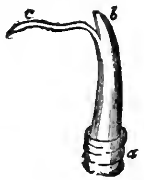

Fig. 67.—*Penis of the Moschus Moschiferus.*

a, Prepuce.
b, Glans penis.
c, Urethra.

and projects beyond the extremity of the glans (fig. 67) The *prepuce* is long, and at its mouth is furnished with a brush of hairs, as already noticed. In its usual state the penis lies rolled up within the belly. Its structure, and the form of the urethra and prepuce, may be readily made out by examining the musk bags of commerce. The preparations before you are from this source.

2. *Female genital organs.* — We are indebted to Pallas for an interesting account of them, both in the impregnated and unimpregnated state. The only remark I shall extract is, that no vestige of the musk sac can be observed. This statement does not agree with that of Valmont de Bomare, who erroneously says the

female is provided with a sac like the male, but that the contents are different.

Contents of the musk sac.—Pallas states, that in young animals he found the sac empty and contracted; in adults it contained about a drachm and a half of musk, and in old animals more than two drachms. But the weights of musk here mentioned must be below the average, since there is generally more than two drachms in each *dried* pod of Chinese musk, and frequently nearly three. Gmelin says, that in the fresh state it had the consistence of an electuary, and was of a reddish brown colour.

Function of the musk sac.—The function of the musk sac is evidently to secrete and retain musk; but what is the use of this substance? When we take into consideration the situation of the sac, its existence in male adult animals, and its analogy to other odoriferous sexual secretions, we can have but little doubt respecting its relation to the sexual functions. It is possible that, by the action of the cutaneous muscle, and by the pressure of the animal, some musk may be squeezed out, and by its local action operate as a venereal excitant. Among the Chinese, musk has long been celebrated as an aphrodisiac. Gmelin tells us that the Persian females use astringent and aphrodisiac unguents, containing alum and musk, for lascivious purposes; and Prosper Alpinus makes a similar statement of the custom of the Egyptian females. Berzelius remarks that it is supposed the physiological destination of musk is to render the search for the male more easy to the female at the rutting season, as the animal lives isolatedly. If the female only had the sac, I could easily believe it was to enable the male to find her; but as it is, I think this explanation very unsatisfactory.

One thing is certain, other animals are furnished with secretory organs more or less analogous; for example, the *antilope gutturosa*; a drawing of whose preputial gland has been given by Pallas. (Fig. 68.) The preputial sacs of some rodentia, especially of the *castor fiber*, are also analogous. One remarkable distinction, however, exists between the musk and castor sacs; which is, that the former is found only in the male, the latter in both sexes.

Geography of the musk animal.—It is exclusively a native of Asia, and is found, according to Brandt and Ratzeburg, on the mountains of this part of the world, within the 16° and 58° of north latitude, and the 92° and 155° of longitude; more especially between the Altai and Himalaya mountains. China, Cochin China, Tonkin, Tartary, and Siberia, have all

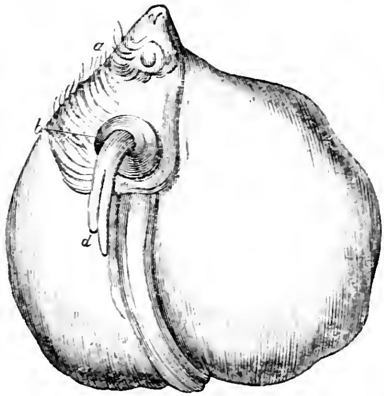

FIG. 68.—*Præputial Follicle of the Antilope Gutturosa.*

a, Orifice of the follicle.
b, Prepuce.
d, Penis.

been celebrated for it. The animal is timid, and dwells on cold mountainous districts, where coniferous plants are found.

Mode of catching the animal.—Various methods are adopted for obtaining the musk animals. Sometimes they are taken by snares or gins, sometimes by pitfalls, sometimes by shooting with the bow and arrow. The Tungouses, one of the native tribes of Siberia, employ the bow and arrow only.

Commerce and varieties of musk.—Musk bags are brought to this country principally from China and Russia, and sometimes from other parts, as Bucharia. I shall confine my description to the two first.

1. *China musk*, also called *Tonquin* or *Thibet* musk, is brought to this country in little rectangular boxes, about 7¼ inches long, 4⅝ inches broad, and 4½ deep; covered externally by silk, and lined with sheet lead and paper. These boxes contain about twenty-five sacs, or pods, each wrapped separately in paper. You observe that the box before us is marked on the outside "*Lingchong Musk*;" and on the inside of the lid is a rude Chinese representation of the musk hunters, some shooting the animal, others cutting out the musk bag.

The pods of China musk are roundish, or somewhat oval; generally broader at one end than at the other. The hairs are brownish-yellow, or greyish, or whitish, bristle-like, and stiff; arranged in a concentric manner around the orifice of the sac. The pods are about 2½ inches long, and 1¾ inches broad.

The following are the weights of six pods of musk of commerce:—

	Drachms.	Grains.
1	5	30
2	4	30
3	8	37½
4	9	47½
5	5	20
6	3	30
Total	37	15
Average ..	6	12½

The relative proportion of musk and coats of the sacs in these were as follows:—

	Drachms.	Grains.
Musk (grain)	16	15
Coats of the sacs ..	21	0
Total	37	15
Average quantity of musk in each sac	2	42½

For this information I am indebted to Mr. Noakes, druggist, of Snowhill.

The musk contained in these pods is granular, of a dark-brown colour, unctuous to the feel, of a bitter and aromatic taste, and of a well-known intense and remarkable odour. A number of anecdotes are told respecting its odorous property, which, although probably true, are almost incredible. Thus Alston says that a clean cork used as a stopper to a phial containing musk, and which it seemed never to have touched, in 1712, retained the scent more than twenty years after. It is also said that a single grain may, during many years, fill the air of a large apartment with its perfume, without its weight diminishing in any appreciable degree. These and other similar statements are sometimes instanced as proving the extreme subtilty of the particles of matter, and, therefore, the probability that matter is infinitely divisible. When mixed in small quantities with other odorous substances, it augments their smell without much imparting its own; and hence it is extensively used by perfumers. The odour of musk, which is promoted by the addition of a few drops of solution of potash, is not, however, peculiar to this substance, various other animals having the same; some vegetable also; and it has even been said some mineral solutions. As instances of other animals having a musky smell, I may quote the musk ox, (fig. 69), the musk rat, the crocodile (which

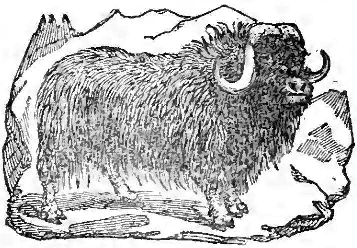

Fig. 69.—*Musk Ox.*

has a submaxillary gland, secreting an unctuous musky substance), the anas moschata, or Barbary duck, the formica rufa, &c. Some persons have declared the urine of a male cat to be similar in its smell to musk; though, I confess, I never could perceive the analogy. Among vegetables which have a musky odour, I shall only quote the erodium moschatum, malva moschata, and centaurea moschata.

The finest musk, on examination, appears to consist of dark-brown globules, usually intermixed with hairs and pieces of fine membrane.

2. The *Siberian*, *Russian*, or *Kabardine*, is considered an inferior sort. The pods are said to be more oblong or oval than the China kind; the hairs longer and whiter. But I have examined large quantities of Siberian musk, the pods of which were not distinguishable from those of China by any of these characters. The only invariable distinction I have observed is in the scent; which is remarkably different from that of the China kind: it is much less powerful, and more nauseous and disagreeable, being somewhat empyreumatic. Here are specimens. Geiger says it is sometimes accompanied by an odour similar to that of the sweat of a horse. This kind of musk is imported in wooden boxes, and all the pods that I have examined were in a good state of preservation; but frequently, I am told, this is not the case.

Chemical properties.—Musk has been analysed by Thiemann, by Guibourt and Blondeau, by Buchner, and by Geiger and Reimann. The substances which they have detected are the following:—

1. Volatile matters	Odorous matter. Water. Ammonia Volatile oil		
2. Fatty matters	Saponifiable	Solid .... Liquid	Stearine. Oleine.
	Not saponifiable	....	Cholesterine.

3. Resin.
4. Alcoholic extract (osmazome ?).
5. Aqueous extract (musk acid of Buchner).
7. Free acid (lactic ?).
8. Salts.

1. *Volatile matters.*—The first matter deserving our consideration is the *odorous principle.* It is a curious fact, that although the smell of musk is so strong and diffusive, yet the constituent of the musk which is the source of it, is not volatile. Analogy would lead you to suspect that it depended on a very volatile oily matter; but experiment seems to negative such an opinion.

Here is water distilled from musk: it has, indeed, the musky odour, but the residue in the retort retains the same. In fact, no distillation will deprive musk of its remarkable smell. What is the nature, then, of the substance in musk which is the cause of it? You will, perhaps, be surprised to hear, that hitherto it has evaded the researches of chemists. It is organic, for it is destructible by heat; it is not peculiar to musk, since so many other substances exhale an analogous odour. What, then, is it? Here is an experiment which throws some light on it: I place a little musk over a basin of sulphuric acid, and under this air-pump receiver. By exhausting the receiver, and allowing the musk to remain for some time in this position, it becomes well dried; the process being called "Leslie's method of desiccation." Now it is said that musk thus deprived of all its moisture is inodorous; but that by exposure to the air, by which it becomes damp, or by the addition of water, it regains its well-known smell.

Though I have several times performed the experiment, I cannot say that I have been able to satisfy myself that the musk becomes scentless. [The experiment was here performed; the musk, however, was not wholly deprived of its odour.] Geiger and Reimann say they have performed this experiment thirty times successively on the same portion of musk; that each time, by drying, it lost its odour, and subsequently regained it by the agency of moisture. Is it the result of putrefaction of one or more of the constituents of musk? The circumstances already mentioned, as well as some others, favour this notion; and they are easily accounted for by it. It is said that bile at a certain period of decomposition has a musky smell: if so, this is in favour of the opinion here mentioned. Robiquet has a notion that many odorous substances owe their odour to a certain quantity of ammonia, which is disengaged, and carries with it substances not otherwise volatile; but that these mask the smell of the ammonia.

In applying this hypothesis to musk, it must be admitted that it harmonizes well with several of the circumstances observed. It is true that musk emits ammonia, that water distilled from musk contains ammonia, and that liquor potassæ (which facilitates the evolution of ammonia), added to a solution of musk, heightens its odour. Neumann says, "some report that musk which has lost its smell, recovers it again on being hung in a privy; and that this is the common practice among the perfumers." If the statement be correct, it is certainly in favour of Robiquet's opinion; though, upon the whole, it is founded on very slender evidence.

Musk contains a little carbonate of ammonia and water: the quantity of these two substances appears to vary, according to the experiments of the following chemists:—

In 100 *parts of musk*—

	Water and Carbonate of Ammonia.
Thiemann found	15
Guibourt and Blondeau	47
Buchner	17·6
Geiger and Reimann	41

2. *Fatty matters.*—I have digested some musk in æther, and you observe I have obtained a slightly-coloured liquid, which has in solution a quantity of fatty matter, with some resin. I place a little of this ætherial tincture on glass, and by the evaporation of the æther a thin crust of fat and resin is obtained. The fatty substance consists of stearine, oleine, and cholesterine: the last mentioned substance has been so termed (from χολὴ, *bile*, and στεαρ,

suet or *fat*) because it is found in biliary calculi, sometimes in the pure and white state (as in this preparation), but usually mixed with other substances which colour it. This cholesterine is distinguished from the other fatty matter of musk by its not forming a soap by the agency of an alkali. Nysten says musk contains adipocire (so called from *adeps*, fat, and *cera*, wax), a substance which is formed by the spontaneous decomposition of fatty bodies, and with which cholesterine was at first confounded. It is not at all improbable that by the spontaneous decomposition of the constituents of musk, some adipocire might be formed; for this substance is an ammoniacal soap, and we have already mentioned that musk evolves ammonia, and we know that the acid (margaric) of this soap is readily obtained by the action of the ammonia on stearine. John says musk contains wax, but possibly that which he obtained was cholesterine.

3. *Resin* is a constituent of musk, to which I have already alluded. It is contained both in the etherial and alcoholic tinctures of musk. In order to show you that this alcoholic tincture contains resin, I must proceed as follows (for the addition of water to the tincture will not precipitate the resin):—Place some tincture on a capsule, and evaporate; when it has become sufficiently concentrated, add water, and you observe the white flocks of resin, which are thrown down. This resin has a bitter taste, and a musky odour.

4. *Osmazome* is a term which Thenard applied to an alcoholic extractive matter of meat, on account of its odour. It is derived from ὀσμὴ, *odour*, and ζωμὸς, *broth*. Berzelius, however, asserts it is a mixture of animal substances. Whatever its nature may be, it is a constituent of musk.

5. *Musk acid* of Buchner, or the *aqueous extract* of Berzelius, is another constituent of musk deserving notice. Its nature is imperfectly known. It exists in musk in combination with potash and ammonia; so that if it be really an acid, as Buchner fancies, we may say musk contains *muskates of potash* and of *ammonia*. Its characters are the following:—

It is insoluble in water by itself, but when combined with potash or ammonia, is soluble. Hence an aqueous infusion of musk holds it in solution, in consequence of the alkali with which it is combined. The acetic and gallic precipitate it, probably by removing the base. Here is an aqueous infusion of musk, and you observe acetic acid produces some coloured flocculi, while gallic acid causes a cloudiness. It is possible that the precipitate in these cases may be a compound of the acid employed with this aqueous extractive. Certain salts also precipitate this substance; for example, sugar of lead. [The experiments were shown on an infusion of musk.] Probably the matter here thrown down is a kind of muskate of lead, an acetate of potash and ammonia remaining in solution.

Three substances (namely, *fibrine*, *albumen*, and *gelatine*) have been stated to be in musk, the existence of which is doubted by some writers. Berzelius supposes this aqueous extract has been mistaken for them.

The *salts* present in musk are of little importance medically. The following have been detected: sal ammoniac, chloride of sodium and of calcium. Hence nitrate of silver precipitates an infusion of musk.

I shall conclude the chemistry of musk with a tabular view of two analyses:—

Guibourt and Blondeau.

1. *Volatilized by drying* — Water	46·925
Ammonia	0·325
2. *Extracted by æther*—Stearine, oleine, cholesterine, fatty acid with ammonia, traces of a volatile oil	13·000
3. *Extracted subsequently by alcohol* (alcoholic extract of Berzelius; osmazome of Thenard)—Cholesterine, fatty acid with ammonia, sal ammoniac, chloride of potassium, of sodium, and of calcium, and an undetermined acid combined with the same bases	6·000
4. *Extracted subsequently by water* (aqueous extract of Berzelius)—Gelatine, carbonaceous matter soluble in water, the preceding chlorides, and an undetermined combustible acid	19·000
5. *Extracted subsequently by ammonia*—Albumen and phosphate of lime	12·000
6. Fibrous tissue, carbonate and phosphate of lime, hairs, and sand..	2·750
	100·000

Geiger and Reimann.

1.	Peculiar volatile substance	Quantity undeterminable.
2.	Ammonia	Ditto
3.	Peculiar, fixed, uncrystallizable acid	Ditto
4.	Stearine and oleine	1·1
5.	Cholesterine (with some oleine and resin)	4·0
6.	Peculiar bitter resin	5·0
7.	Osmazome (with sal ammoniac, chlorides of sodium and calcium, and the above acid, partly free, partly combined with the bases)	7·5
8.	A mouldy-like substance, in part combined with ammonia, by which it is made soluble in water, with small quantities of phosphates of lime and magnesia, sulphate of potash, chlorides of potassium and sodium, carbonate of potash or soda, and trace of iron	36·5
9.	Sand	0·4
10.	Water, some volatile odorous matter, the above acid in part combined with ammonia, and loss	45·5
		100·0

Adulteration.—Musk being a very valuable article, we are easily prepared to admit the probability of its being extensively adulterated; and if we are to believe the statements made in books, it is difficult to procure a specimen of this substance which is absolutely pure. My own observation does not, however, coincide with these assertions; I think that at the present time, in this country, musk is not much adulterated; though sand, stones, &c. are sometimes found. It is said that the bags have been imitated by the skins of animals, or by the scrotum of the goat. I have never seen any of these; nor do I believe they are now to be met with. If ever the fraud should be attempted, it would, I presume, be easily discovered.

We are told that the musk pods are sometimes opened, and various foreign substances introduced to increase the weight; for example, pieces of lead, &c. I have frequently seen pods which, on examination, have been sewn up around the edges, or at the orifice; but it appeared in most cases as if this had been done to prevent the loss of the musk, rather than that the bag had been opened for the purpose of adulteration.

Dried blood, bile, snuff, &c. are likewise said to be mixed with musk. One of the best tests for the genuine, is that an infusion of it does not precipitate a solution of corrosive sublimate; at least the musk before me, which I believe to be genuine, gives no precipitate, as you observe; and Berzelius and Geiger both lay great stress on this test. Curiously enough, in Dr. A. T. Thomson's work on the Materia Medica, and in his London Dispensatory, we are told that a solution of corrosive sublimate precipitates infusion of genuine musk, and not the spurious; a statement which is incorrect, according to the experiments of Berzelius, Geiger, and myself. [The experiment was here tried.] Besides this test of good musk there are others: acids (especially the nitric) precipitate infusion of genuine musk; as also sugar of lead, and infusion of nutgalls. [The experiments were shown.] By combustion a grey ash is left behind; whereas dried blood leaves a reddish ash.

The *physiological effects* of musk next deserve our attention. The latest, and perhaps the best, series of experiments made on this subject are those of Jörg with the society to which I have already alluded in speaking of the effects of castoreum. The experiments were conducted on five men, two women, and two lads; and the quantity of musk taken was from two to fifteen grains, in water, or mixed with magnesia. The primitive effects were eructation, weight at the stomach, diminution or increase of appetite, dryness of the œsophagus, heaviness of the head, vertigos, and headache. The secondary effects were more marked on the encephalon than on the digestive canal: disposition to sleep, faintness, and a feeling of heaviness in the whole body. Lastly, deep and long-continued sleep. In very large doses the action on the nervous system was very marked; trembling in the limbs, and even convulsions, were observed. The pulse was rendered more rapid and fuller.

These symptoms show that musk is a cerebro-spinant or a stimulant to the nervous system, and that it also acts on the organs of digestion and circulation. In some persons the nervous

system appears to be peculiarly susceptible of the odour of musk; for it is reported that headache, vertigos, and even fainting, have been produced by it. When the digestive apparatus is previously in a state of irritation, musk increases the local disorder, giving rise to pain, nausea, vomiting, and diarrhœa. Sometimes the stimulus of musk is extended to the sexual organs, as is shewn by the increased venereal excitement, or the production of the catamenia. In persons disposed to epistaxis, the use of musk will sometimes bring on this disease. Occasionally it excites sweating; at others an increased discharge of urine.

Like all other agents which act on the nervous system, the operation of musk seems to be somewhat uncertain. While in some cases the odour of it merely will produce serious symptoms, as I have already mentioned, in others large doses have been administered internally with very little effect.

It is usually believed that musk becomes absorbed. Barbier states that the urine and the sweat of persons who have taken this substance are powerfully impregnated with its odour—now and then so strongly, that the hand applied, for the purpose of feeling the pulse, retains the odour for some time. On post-mortem examination, the brain and the cavities of the chest and abdomen, in those who have taken it during life, somtimes emit a strong smell of musk.

We have also the evidence of Tiedemann and Gmelin in favour of the opinion that it is absorbed. Their experiments (to which, on a former occasion, I directed your attention) were made with the view of determining the question of lacteal or venous absorption; and one of the odorous substances employed was musk. This medicine was given to animals, and its odour was subsequently discovered in the blood of the splenic and portal veins, but not in the contents of the lacteals. Notwithstanding this apparently positive evidence of the absorption of the odorous particles of musk, we find Professor Jörg denying the inference which has been drawn. He says that numerous experiments have satisfied him that the urine and fæces of persons who have taken musk do not acquire a musky smell, and that the mistake in this respect has arisen from the frequent musky eructations which communicate this odour to all surrounding bodies.

What is the active constituent of musk? I do not think we are prepared yet to answer this question. We are not necessarily to infer that it is the same substance which is the cause of the odour, for the odorous principle of opium and of ipecacuanha is certainly not their active principle.

Uses.—The effects of musk, already alluded to, show that it is a remedy which will be useful where we want to excite the nervous system; and, *vice versâ*, that it will be hurtful where there exists a determination of blood to the brain, and in those constitutions denominated plethoric. The cases in which experience seems to have shown musk is sometimes useful, are the following:—

1. Those diseases which are attended with convulsive movements, and which, therefore, are called spasmodic. Such, for example, as hysteria, epilepsy (especially of children, and where the disease does not depend on organic changes, or on plethora), chorea, and even in some cases of tetanus. The employment of musk here has led to its denomination of antispasmodic.

Dr. Cullen, on whose practical information I place the greatest reliance, says, "I maintain that musk (when genuine) is one of the most powerful antispasmodics that we are acquainted with. I have found it, with Dr. Wall, to be a powerful remedy in many convulsive and spasmodic affections, and in some of a very peculiar kind. I had once a gentleman affected with a spasm of the pharynx, preventing deglutition and almost respiration. This, when other remedies had failed, was relieved by the use of musk, which often shewed its power; for the disease continued to recur at times for some years after, and was only obviated or relieved by the use of musk."

As musk in large doses excites tremblings and convulsions in the healthy state, while it is beneficial in convulsive diseases, it is considered by the followers of Hahnemann to be in these cases a homœopathic remedy.

2. In *low fevers* which are accompanied with delirium, twitchings of the muscles, a small contracted pulse and convulsions, musk has been occasionally employed, and with benefit. Like opium, its use in these cases is always uncertain—in one instance relieving, in another increasing the malady, though the cases may be to all appearances parallel.

3. In *retrocedent gout*, as where gout attacks the stomach or the head, giving rise to headache or delirium, musk has been found beneficial. Cullen relates a case where immediate relief was obtained by the exhibition of fifteen grains of genuine musk.

4. Lastly, during the late severe visitation of malignant cholera, musk was one of the remedies tried. I saw it employed several times, but without obvious relief. The experience of others was various; but

the result is, that practitioners formed a very low estimate of its power in this disease.

Mode of administration.—It is best given in substance; indeed, this is the only proper way of exhibiting it. We may form it into boluses, or suspend it in water by means of some mucilaginous or saccharine fluid.

The formula of the London Pharmacopœia for "*the musk mixture*," is one drachm of musk, the same quantity of powdered gum and of sugar, and six ounces of rose water. But you will find it much better to employ twice or thrice the quantity of gum, and at least half as much again of musk, so that one fluid ounce would then be a dose; whereas a larger quantity is now required to be given.

In the Dublin Pharmacopœia a "*tincture of musk*" is ordered, consisting of two drachms of musk to a pint of rectified spirit. It is evident, however, that we must give four ounces of rectified spirit, if we wish to give fifteen grains of musk.

The "*essence of musk*" of the shops is usually prepared from the musk sacs after the musk has been extracted. They are digested in spirit; and to promote the odour a small portion of subcarbonate of potash is sometimes added. The following is a

Formula for essence of musk.—Take of grain musk, fourteen drachms (or of the membranes of the musk pods, seven ounces); boiling water, half a pint. Digest until cold; then add, rectified spirit of wine, six and a half pints; subcarbonate of potash, half a drachm. Digest.

The above was given me by a druggist, as the formula usually adopted.

REMARKS ON CERTAIN THEORIES REGARDING THE SOUNDS OF THE HEART; WITH THE SUGGESTION OF A FRESH HYPOTHESIS.

To the Editor of the Medical Gazette.

Sir,

Reading lately the third edition of the work of Dr. C. J. B. Williams on the Diseases of the Chest, I observed that he has prefaced the third part, relating to affections of the heart, by detailing a new set of experiments which he instituted for the purpose of further elucidating the cause of the sounds of that organ. From the observations which he made during the course of these experiments, he arrived at the conclusions that the first, or prolonged dull sound (which occurs at the time of the ventricular systole), is entirely caused by the muscular contraction itself, of the ventricles; and that the second short sound is owing to the shutting to of the semilunar valves by the re-action of the arterial columns of blood, at the moment of the ventricular diastole.

The idea of the first sound depending on muscular action is, I believe, originally Dr. Williams's; he mentioned it as being probable in the first edition of his work, though he then brought forward no direct evidence in proof of his opinion. Some authors, and among others M. Magendie, have supposed that Laennec believed the sounds of the heart to depend on this cause; but I think he never attempted to give any explanation of their physical origin. The view of the production of the second sound by the closing of the arterial valves, has been supported by the opinion of several writers; among others, M. Rouanet, Mr. Carlile, and M. Bouillaud, who have founded their hypotheses on various arguments.

The results of the experiments made by Dr. Williams, from which he drew his conclusions, appear very satisfactory; and on first looking over them, I thought that they afforded clear proof that his theory of the production of the sounds was correct; but on a more careful investigation of the different points in each experiment, and by considering the manner in which the various phenomena occurring in disease could be explained by these causes, I observed that different deductions might be drawn from the same observations; and that it was very difficult to account for the production of many morbid sounds by the above theories.

Thinking over these circumstances, and considering in what manner a better explanation might be afforded, I have ventured to bring forward a fresh hypothesis, stating the arguments upon which I found my own opinions, and my reasons for rejecting those of Dr. Williams.

I will commence with the latter, first briefly stating the observations upon which his theories rest.

1. During the first experiment which he has detailed, when the heart was exposed, and its action continuing by passing his finger through the mitral

orifice into the left ventricle, and pressing on the right, so as to stop, as he considered, all influx of blood, the ventricles continued to contract, and the first sound was still heard, though less clear than when the circulation was allowed to continue. 2. The same phenomena were observed when both arteries were severed from the heart.

From these facts it is inferred that the first sound depends solely on the muscular contraction of the ventricles.

With regard to the experiments on the second sound:—1. It was heard more clearly over the origin of the aorta and pulmonary artery than on any other part of the heart. 2. When pressure was made for some seconds on the origin of the aorta and pulmonary artery, the second sound ceased. 3. When the closure of the semilunar valves was mechanically prevented, by holding them back, so as to allow of regurgitation, the second sound was diminished, or stopped. It is concluded from these observations that the second sound is caused by the shutting to of the semilunar valves.

In opposition to these deductions, I must say that I think with Dr. Forbes, "that the two sounds, though characteristically different, have so great a similarity, and are so allied both in time and place, that it is unphilosophical to attribute them to different causes, but that in all probability they depend on some modification of the same;" and as I cannot exactly agree with Dr. Hope, who says that both sounds are caused by the collision of the particles of blood in the ventricles during their systole and diastole; or at all assent to the opinion of M. Bouillaud, M. Rouanet, and Mr. Bryan, who think that the first sound is produced by the shutting to of the auricular, and the second by that of the arterial, valves; I must find some other cause which will explain the production of both sounds on the same principle, without being open to the objections to which those that I have mentioned are liable.

But let me return to my reasons against the first sound being the product of muscular contraction.

In the first place, I think it far from proved that the contraction of muscles produces any appreciable sonorous vibrations. If the stethoscope is applied to a muscle in action, some sound is certainly heard both while it contracts, and also while it becomes relaxed, or returns to its original position. It is very possible that this sound altogether is only occasioned by the slight movement of the part against the end of the instrument, which is unavoidable when the muscle is in action. But granting that the sound heard is produced by the muscular movement itself, it is quite inadequate in intensity to account for the first sound of the heart. Listen, for instance, to the gluteus maximus in action, and then to the left side of the chest; where will you hear most sound? and which is the larger muscle, the one which I have mentioned, or the heart? Again, in dyspnœa from pleurodynia, where the diaphragm has to perform the whole function of inspiration, can its contractions be heard by the stethoscope applied to the chest?

Dr. Williams says, that when the layer of muscular fibre becomes thinner and more simple, as in ventricular dilatation, the sound from its contraction becomes louder and clearer than usual. If this is the case, why do not the auricles produce any sound? They certainly have muscular parietes; and if the vibrations are increased in the inverse ratio to the thickness of the walls, should give rise to a louder sound during their contraction than the ventricles; but, as has been clearly proved by the experiments of Hope and others, they do not cause any that is appreciable to the ear. As to the results of the observations on the first sound, made during the experiments of Dr. Williams, in all probability the circulation of blood was not entirely impeded through the heart by the passage of the finger into the mitral orifice, at any rate on the right side; and that therefore the sound still continued, though much diminished in intensity. As to the experiment of cutting off both the arteries, the mode in which it was conducted is mentioned very briefly, or I think that some fallacy might be detected in the result.

The most probable mode of production of the first sound is, that it is caused by the rush of blood over the arterial valves, and into the orifices of the aorta and pulmonary artery, at the time of the ventricular systole. Any alteration, from disease in the size or regularity of the openings, will modify the sound, and give rise to the different bruits which

are heard in disease of the arterial valves. In this mode the natural and unnatural sounds are referred to modifications of the same cause, which is more probable than to suppose them to have different seats; for the healthy sound does not merely seem to be accompanied by an unnatural one, but to be itself actually altered. It may be said, if that was the seat of the sound in the arterial orifices, it would be heard more intensely opposite that spot than at the apex of the heart, the reverse of which is the case. But I consider that the vibrations produced by the succession of the particles of fluid against the valves, are propagated backwards to the mass of blood in the ventricles; therefore the sound is heard over the whole surface of the heart, but more particularly at the apex, in consequence of that part being in more immediate contact (by the impulse) with the sides of the chest, at the time that the first sound is produced. In corroboration of this, morbid alterations of the first sound accompanying diseased arterial valves are always heard most intensely in the same spot (the apex), though I believe all pathologists agree in their seat being at the commencement of the arteries.

According to this theory, how can the phenomena of dilatation and hypertrophy of the ventricles be explained? Why, in the former disease the sound is rendered shorter, by the muscular walls contracting more quickly, on account of their thickness; it becomes louder and clearer, in consequence of the less thickness of muscle which the sound has to travel through; and it is heard over the larger space, from the extension of the sides of the cavity.

In hypertrophy, it has been said that the greater force with which the blood is propelled into the vessels, should increase the sound, instead of its being, as it is in that disease, diminished; but I think that there is no proof or probability of such being the case. If the quantity of fluid is not increased, nor the orifice through which it is transmitted diminished, it makes but little difference, as to sound, whether it passes rather more quickly or slowly; in fact, it will cause less noise in the former than the latter case; and in hypertrophy, the greater thickness of the walls of the ventricle, through which the sound has to be conveyed, will much diminish its intensity.

I have not yet said any thing about the second sound of the heart. Both the seat and mode of production of this phenomenon are points on which there has been much discussion and great difference of opinion; some referring it to the action of the arterial valves; others to the rush of blood against the sides of the ventricles, or the knocking of the heart against the inside of the chest, which M. Magendie most improbably supposes to be the cause of the second, as well as the first sound.

Thinking it most plausible to refer both sounds to similar causes, I consider that the second is produced by the rush of blood through the auriculo-ventricular orifice, and over the mitral and tricuspid valves, at the moment of the ventricular diastole. The difference in duration and character between the two sounds may be explained by the greater suddenness and quickness with which the blood rushes into the ventricle, than the muscular contraction can force it out again.

But from what arguments do I come to these conclusions? and upon what grounds do I reject those of Dr. Williams and others? First, is it probable that the valves close with sufficient force to produce such a loud sound, or, in fact, any at all? I think not; for they most likely act, not suddenly, but gradually. And if the arterial valves, by shutting, have such an effect, why are the auricular silent? They may as well be supposed (as is the opinion of some writers) to produce the first sound.

As to the experiments of Dr. Williams, he says that the short sound was heard more clearly over the region of the aorta and pulmonary artery, than on any other part of the heart when it was exposed. This would also be the case were its seat in the auriculo-ventricular orifice instead of the semilunar valves; for they correspond very nearly in situation. And if, as is probably the case, the vibrations are principally felt in the auricles, those cavities are so closely connected with the origin of the great arteries, that the sound will be heard most clearly over them.

With regard to the observation that pressure on the origin of the aorta and pulmonary artery stopped the second

sound, this might occur from the passage of blood being impeded from the ventricles, and therefore not a sufficient quantity rushing in with the diastole to cause perceptible sonorous vibrations. The reason of the second sound being diminished or lost, when the closure of the semilunar valves was mechanically prevented by introducing an instrument and holding them back, is sufficiently clear; the regurgitation which ensued, filling the ventricles in great part from the arteries, and not the auricles, and the hissing murmur occasioned by the backward passage of the blood over the injured valves, prevented the enfeebled sound which remained from being heard.

A further reason for my considering the seat of the second sound to be at the auriculo-ventricular orifice is, that when the mitral valves are diseased, this sound is altered, accompanied with a murmur, the first sound remaining natural, unless the morbid change is so great as to allow of regurgitation, when we have a bruit with both sounds. In lesions of the aortic valves, where much regurgitation does not take place, the second sound is unaltered—only the first changed. Now it is probable that obstructive disease of these valves would prevent them from closing with sufficient freedom to produce the clear sharp sound, if it had its seat there. And in a case described by Dr. Hope, where there was extensive disease of the aortic valves, so that they were in a state of complete rigidity, the second was heard very clearly on the left side of the heart before death.

From these and other circumstances, I have arrived at the conclusions stated above, but I must allow that fresh observations and new experiments are required to confirm these theories, particularly the mode of production of the second sound.

Since the above ideas occurred to me, I have understood that there is a committee appointed in Dublin for the purpose of investigating the sounds of the heart; and I believe that they have come to the same conclusions with myself as to the origin of the first sound, but have not decided concerning the second. Their proceedings are, I think, not yet published, and I am not acquainted with the experiments from which they suppose the first sound to be caused by the blood rushing over the semilunar valves.

I am, sir,
Your obedient servant,
R. H. Meade,
Clinical Clerk at St. Bartholomew's Hospital.

St. Bartholomew's Hospital,
Dec. 1, 1835.

P.S. If you should think these observations of any interest, and can find room for their insertion, you will oblige me by giving them a place in the Medical Gazette.

OBSERVATIONS ON THE TRICHINA SPIRALIS.

To the Editor of the Medical Gazette.

Sir,

Another instance of the trichina spiralis infesting the human body, having been recently met with in the dissecting room of St. Bartholomew's, the matter has again excited considerable interest; and as I am not aware of the occurrence of any other case since the publication of Mr. Owen's description of this entozoon in April last, I conceive that any further information upon the subject will be the more acceptable. This I feel some confidence in offering, inasmuch as I find the opinions which I previously entertained have been in almost every respect confirmed.

I take this opportunity, therefore, of communicating the result of my observations upon specimens procured from this as well as from the two former cases mentioned in Mr. Owen's paper*, read before the Zoological Society; and to which paper I refer for the general description of the animalcule, limiting myself here chiefly to those points upon which I am enabled to give additional information, or in which my observations have differed from those of Mr. Owen. In the first case, which occurred early in February, my attention was directed principally to the peculiarities of the cysts within which the worms are contained; and as the worms

* An abstract of this paper was published in the Gazette for April 25th of the present year. The whole paper will shortly appear in the 4th vol. of the Zoological Transactions.

themselves were all dead, and I had not then acquired a facility in extracting them, I do not place so much reliance in my observations upon them as upon those from the second case. This case occurring three weeks after the former, afforded me the opportunity of examining the worms alive. My attention was then, for the first time, attracted by the appearance of something like an alimentary canal, distinct from the parietes of the body, and extending from one extremity of the worm to the other. This appearance I found to be presented, more or less distinctly, by a great variety of specimens, but in consequence of the extreme delicacy and transparency of every part of the worm, this supposed structure was indicated by only a very faint outline. After examining a great number, I met with one in which the whole course of this apparent canal was clearly defined. This specimen I immediately copied by means of a camera lucida, fixed to the eye-glass of the microscope, in order to insure the accuracy of the representation. It forms fig. 3 in the annexed engraving; reference to which will render the description of this part more intelligible.

Commencing from the large end of the worm, *a*, the canal is seen bounded by two slightly irregular lines, running parallel to each other for a distance of rather more than one-fifth of the length of the body, where they terminate in a transverse line, *b*, presenting a slight concavity towards the large end, which line I have observed in almost every specimen that I have examined. From this point the canal puts on a sacculated appearance, *c c*; and these sacculi appear as if bound down by a line extending along the surface of the canal, in the direction of its axis. This sacculated appearance becomes gradually lost towards the smaller end, where the part assumes a zig-zag, or perhaps spiral course, *d*, and at length terminates at the small end *e* *.

But the lines indicating the course of this canal generally become so faint towards either extremity, that I have seldom been able to trace them so far as in the specimen figured; although the central puckered part represented at *c c* may be seen in most instances.

As I had observed these appearances in all positions of the animal, I could not attribute them to any accidental creasing of the internal parts, resulting from the curvatures of the body, nor could I explain them in any other way than by supposing that they were produced by a distinct tube contained within the external parietes, and having little or no connexion with them; this tube appearing to be considerably longer than the body of the animal, and hence the puckering would result from its being collected into a smaller space.

These suspicions were confirmed when I observed in one of the worms a distinct motion of the inner tube taking place, a large portion of it being slowly drawn backwards and forwards within the body of the animal, and the action being repeated eight or ten times, so as to leave very little doubt in my mind as to the separate existence of this part *. As, however, I might have been deceived by a motion communicated to the contents of the inner tube, and not taking place in the tube itself, I was still anxious for further proof; which was afforded me the other day, when, on cutting across one of the living specimens (from the last case), I observed the inner tube projected gradually, as if by its own elasticity, from the cut extremity of the body, until a considerable portion protruded. This operation I repeated several times, and always with the same result, the protrusion of the inner tube taking place to a considerable extent, and showing very distinctly the sacculated structure, together with the central line running along its surface.

This appearance is represented in fig. 4; where *a* is the extremity of one of the worms, *b* the point at which the section was made, *c* the length of intestine that has protruded. The granular matter with which the body is filled appears to be contained within this tube.

It may be thought, from an inspection of these engravings, that if the object is fairly represented, the existence of an alimentary canal cannot admit of doubt; but every one accustomed to the microscopic examination of minute animalcules, is aware that it is exceedingly difficult in a drawing to avoid giving too definite an idea of the object to be represented. When, more-

* To avoid confusion in the drawing, the minute granules with which the worm is filled are not here represented.

* I have witnessed this appearaance several times since, though in a less marked manner.

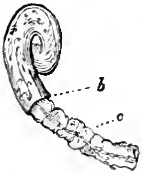

Fig. 3.

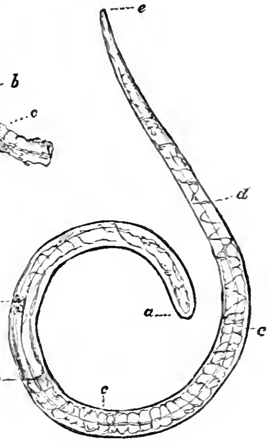

Explanation of Plate.

Fig. 1.—Portion of biceps muscle containing the trichinæ, with their cysts (natural size).
Fig. 2.—A separate cyst, with the worm coiled up in its interior, and seen through the transparent walls.
Fig. 3.—Worm extracted from cyst, shewing the alimentary canal and ovary.
Fig. 4.—Portion of worm showing the alimentary canal protruding from the cut surface.
The last three figs. as observed by powers ranging from 200 to 450 linear measurement.

over, it is remembered that the worm itself is not more than the 700th of an inch in diameter, so as to be scarcely visible to the naked eye, it will be seen at once that the determination of its structure is necessarily attended with considerable difficulty; inasmuch as it requires the aid of a very high magnifying power, which, even in the best glasses, is always accompanied by a corresponding diminution in the distinctness of the object examined. As, in such cases, therefore, great augmentation cannot be obtained except at the expense of clearness of definition, it is necessary to be guided by the constancy with which any particular appearance is presented; and as I have observed the appearances here described, more or less distinctly, in at least fifty instances, I cannot doubt but that they indicate the existence of a structure holding a very important place in the economy of the animal, and which, from its size, form, and situation, I believe to be the alimentary canal.

But the presence of an alimentary canal such as this appears to be, would lead to the supposition of the existence of a mouth and anus. Upon this point, however, I have no very satisfactory evidence to offer. In many of the specimens obtained from the second case, I observed the appearance of a linear mouth at the larger end, as it is described by Mr Owen; but in only one instance could I satisfy myself of the existence of an aperture in this situation, when, from the position of the worm, which happened to be with the large extremity towards me, I was enabled to see *into* what appeared to be an irregular rounded opening. But although I have searched diligently for this appearance in the specimens recently obtained, I have not been able to detect it in any one of them. I thought, however, that in two instances I could distinguish something like an aperture at the small end. These points, however, I leave for further investigation; and from the minuteness of the object they will probably not be determined without great difficulty; but I am anxious that my observations upon the former point should be confirmed, because, if found to be correct, they will have the tendency of approximating the trichina to the more highly organized groups of entozoa which constitute the

vers cavitaires of Cuvier, rather than to the simple parenchymatous forms among which it is now placed.

But there is another point in the organization of this animal which attracted my attention. It consists of an aggregation of small round granules, about a dozen in number, situated at about one-fifth of the length of the animal from the larger extremity, and generally close to that side of the coil which is outermost. It extends about half-way across the diameter of the body, and is composed of larger granules than those which are distributed irregularly through the body; but when viewed with a power of 1000 diameters, each appears to be made up of still smaller granules. This body is represented at *f* in fig. 3; it was present in almost all of the specimens which I examined from the second case, and in about three-fourths of those from the last case. This part I suspect, from its form and situation, to be the ovary. At any rate it cannot be considered an organ necessary to the existence of the *individual*, since many specimens may be met with in which it is entirely wanting, and those apparently of the same age, insomuch that I have met with two in the same cyst, the one having the ovary, and the other not. This latter is a curious point, if it is usually the case, but I am not aware that it is so. Although the entire absence of this organ in some instances may be considered as evidence in favour of the existence of separate sexes, yet in such cases I have not been able to detect any other difference of form or structure that would warrant this conclusion.

Another appearance which I have frequently observed in these worms, is that of a line of small dots running down the centre of the animal, and at a distance from each other of about half the diameter of the body; these dots are tolerably regular in their arrangement, and are situated apparently at the surface of the animal. I have not observed any traces of a nervous system.

With regard to the structure and mode of formation of the double cyst in which the worm is contained, and the relation which these two bear to each other, I think much yet remains to be learned. The investigation of this part of the subject is one of greater difficulty than that of the worm itself, as it will probably require for its complete elucidation that the cysts should be observed in their different stages of development. For this purpose, however, sufficient opportunities have not yet been afforded, since the greater part of the cysts that I have examined appear to have arrived at about the same period of their growth, although I have occasionally seen one of a larger size empty, and split down the middle, as if this were the last stage; whilst, on the other hand, I have met with smaller ones, opaque, and with very thick walls, and sometimes having no worm in their interior, but only a little granular matter; this is, perhaps, an early stage. But these are exceptions to the general form, which are not sufficiently numerous to enable me confidently to draw inferences from them. But although one general form of cyst has prevailed, still this has presented so many varieties in minute points, as to convince me that if these were collected and well arranged, much light might be thrown on the question.

This part of the subject, however, if pursued, would lead me to too great a length: at present, therefore, I shall content myself with selecting from a number of drawings that I have made to illustrate these points, one which shows the form of cyst that I have most frequently met with. This is seen in fig. 2, where *a* represents the outer cyst, *b b*, its two elongated extremities, *c c*, the centres of these, so opaque as to appear black when viewed by transmitted light. These appear to be attached to either extremity of the inner elliptical cyst (as represented at *e*), the walls of which are so transparent as to admit of the worm *f* being seen through them. This form, although the most frequent, is perhaps not the best calculated to show the difference between the inner and outer cysts. This is most distinct in those specimens where the whole of the extremity of the outer cyst is opaque, while the central portion enveloping the inner cyst remains sufficiently transparent to admit of the latter being seen through it.

In most of the specimens from the last case, the whole of the outer cyst was so opaque, that little either of the worm or the inner cyst could be seen, except by dissection. These cysts were much harder than in either of the former cases; and from their greater whiteness, the

speckled appearance which they produced in the muscles was very remarkable. The inner cyst can seldom be displayed by dissection; but I think there can be little doubt of its existence as a separate sac from the outer one; its structure, however, is much more delicate. Once or twice, when it was very firm, I have turned it out entire; but generally only broken portions of it can be extracted. When viewed, however, *in situ*, by transmitted light, its boundaries may be often seen well marked.

I am still doubtful whether the dark parts marked *c c*, fig. 2, belong to the inner or the outer cyst; but, for various reasons, I think to the latter.

One other circumstance I may mention before leaving this part of the subject—namely, that in the last case I found the occurrence of two worms in a single cyst to be quite as frequent as that of a single one; and from one of the former cases I have preserved a specimen containing three. I have not yet been able to gain any particulars with regard to the history of the case from which I obtained the last specimens; but the examination of the body, which was that of a middle-aged man, and emaciated, shewed that the individual had died of phthisis. Crude tubercles were thickly distributed throughout both lungs; and in the upper lobe of each were contained large tubercular cavities, together with others of smaller size in various parts of the lungs. The surfaces of the pleura pulmonalis and costalis were closely united together by firm adhesions, as were also the two surfaces of the pericardium. No other morbid appearances were noticed in the internal organs.

The muscles presented the peculiar speckled appearance produced by the presence of the minute white cysts, in a more marked degree than in the former cases. The superficial muscles were found to contain them in far greater numbers than the deep-seated ones, and especially the broad flat muscles, as the pectoralis major and latissimus dorsi. They were present, however, in a greater or less degree in all the muscles of the trunk and extremities, in those of the eye and external ear, in the tongue and soft palate, the constrictors of the pharynx, and the œsophagus, both the crura, and the radiated portion of the diaphragm, in the levator and external sphincter ani, and the muscles of the urethra. Indeed, the only muscular structures that seemed to be free from them, were the heart and muscular envelope of the stomach, intestines, and bladder, together with one or two other exceptions.

Their unequal distribution in the muscles of the body, and their total absence from certain vital organs possessing the same structure, are interesting points. It does not, however, appear that this exemption extends to all those muscles which are usually considered as involuntary.

As I am not aware that these animalcules have been noticed in any other of the numerous dissecting-rooms in London or elsewhere, except in the case mentioned by Mr. Hilton as having occurred at Guy's*, and probably that also by Mr. Wood, at Bristol†; and as the appearances which they produce have been observed occasionally for some years at St. Bartholomew's (although their nature was not then understood), I cannot help thinking that they may be still overlooked for want of sufficient attention being directed to the subject. I have subjoined, therefore, a drawing, representing the ordinary appearance of a portion of muscle beset with these animalcules (see fig. 1), which, while it may serve to convey an idea of the appearance produced by their presence, will also tend to correct any false estimate that may have been formed of their size, from the very highly magnified views with which these observations are illustrated.

To those who may meet with opportunities of pursuing the subject, the following observations as to the method which I have found best, may not be without use.

To examine the worm, a very thin slice of the muscle, containing about half a dozen cysts, should be placed upon a slip of glass with a drop of water. This being placed on the stage of the microscope, under a lens of a half or a quarter of an inch focus, one of the cysts is to be separated from its attachment to the surrounding cellular tissue, by means of a couple of needles fixed in handles, leaving it, however, adherent

* See Med. Gaz. Feb. 2, 1833.
† Ibid. May 9, 1835.

at one extremity, which serves to fix it, while the other is cut off by a cataract needle, or other fine and sharp instrument, just within the dark line *e*, fig. 2, so as to open the inner cyst, but without injuring the worm. This is the most delicate part of the operation, and requires some practice to effect it dexterously. As soon as the cyst is opened, the worm, which is free within it, generally starts out, from the pressure used during the operation; or its expulsion may be effected by a very gentle pressure upon the opposite extremity of the cyst. Every thing being then removed from the glass except the worm, this is to be covered by a very thin piece of talc, taking care that there is sufficient water between the talc and glass to prevent the worm being injured by pressure. The object may then be examined by a power ranging from 200 to 500 linear measurement, always using daylight in preference to any other. These examinations should be made, if possible, upon the living worms, at least as far as the internal parts are concerned, since the natural appearances are often entirely lost when the worms are dead, or they are replaced by others, which are likely to convey erroneous impressions. The living worms, moreover, will sometimes uncoil themselves, so as to admit of their structure being more clearly seen than when two or three coils are lying over one another, as in the usual position of the animal. The uncoiling, however, may generally be effected by means of a couple of hooked needles.

The cysts are best examined by placing the thinnest possible slice of muscle between two slips of glass, or one of talc and one of glass, and slightly pressing them, so as to distribute the muscle in a thin layer. If the edges of these are surrounded by white paint, so as to prevent evaporation, the specimens may be preserved for several months; but become at length decomposed. This method is far preferable to that of drying and placing them in Canada balsam, which renders the cysts too transparent.

I regret that my observations upon the specimens procured from the last case were cut short by an accident which deprived me for a time of the use of my right hand. This circumstance, together with want of leisure, and the fatigue which accompanies the examination of an object so minute for any length of time, has had the effect of rendering these remarks less perfect than I could wish. As the subject, however, is new, I have thought it better to give them in their present state.

I am, sir,
Your obedient servant,
ARTHUR FARRE, M.B.

Charterhouse Square,
Dec. 2, 1835.

PHYSIOLOGY OF THE FIFTH PAIR OF NERVES

ILLUSTRATED BY A CASE OF CARCINOMATOUS TUMOR DESTROYING THE WHOLE OF THE LEFT NERVUS TRIGEMINUS.

To the Editor of the Medical Gazette.

SIR,

HAVING observed in your journal a short time back some remarks by Mr. Mayo, on the researches concerning the nerves, by Professor Panizza, of Pavia, I find there still exists some difference of opinion relative to the functions of the third or lingual branch of the fifth, and the glosso-pharyngeal branch of the eighth pair of nerves. As the details of the following case, on which I based some physiological observations respecting the senses, read before the Royal Society in the year 1833, appear to furnish very decisive proofs of the functions of the whole of the fifth pair, you will perhaps oblige me by inserting it in the columns of your journal.

In the month of November, 1831, I was called to attend Miss S., aged 55, born of parents in affluent circumstances, and who lived to an advanced age, but in whose family, on the maternal side, there was a disposition to cancer, of which complaint her sister died in 1823, in the fifty-second year of her age. At my first visit to this lady she gave me the following history of her local as well as general health previously to that period. She stated that until the age of fifty years she had usually enjoyed good health, with the exception of an attack of typhus, and afterwards intermittent fever, which however, she added, did not leave behind any results.

In the year 1825 she first perceived a small tumor in the left breast, immediately under the nipple. For some time it occasioned no uneasiness, and during five years remained almost stationary, but at the end of that period it began to enlarge, and ultimately suppurated, and no doubt was entertained by many eminent medical practitioners whom she consulted, that it was decidedly of a scirrhous structure: it did not, however, appear to have excited much constitutional irritation. The loss of some near relatives shortly before this period had produced deep and lasting grief, which preyed incessantly on her mind. In August, 1830, she had an attack of acute rheumatism, from which she did not recover until the month of December following, when she came to London, thinking the change of air and scene might be beneficial to her: but in this hope she was disappointed, having from the same cause relapsed into a state of severe suffering, which during the space of six weeks prevented her returning home. It was about this time that she began to feel an unusual creeping sensation on the left side of her chin, accompanied with numbness and stiffness, and a sort of itching pain. The tip of the tongue was painful and sore, and a constant pain was felt along the whole course of the lingual nerve. The numbness and stiffness gradually extended towards the cheek and left eye, until the month of July, when having received a shock by unexpectedly hearing of the death of an intimate friend, she was greatly alarmed at finding the left eye had turned obliquely inwards, and she subsequently observed that all objects appeared double. The eye regained its natural position for a short time, after which the obliquity permanently returned, and was attended with a sense of pressure at the bottom of the orbit. Soon afterwards the whole of the left side of the head, face, nostril, mouth, and tongue, were deprived of sensation, while their muscular motion remained entire. At this time blisters placed on the temples produced considerable inflammation, but did not excite the slightest pain, and she stated that fomentations which had been applied to the face too hot, scalded it without her consciousness. The globe of the left eye, which, independently of its obliquity, appeared healthy, was quite insensible to the touch, and she felt a conviction that it might be punctured with a sharp instrument without pain. At first, any object brought within its axis of vision appeared quite natural, but for some time before her death the optic nerve had lost its faculty of distinguishing colours, persons appearing to the eye, as she expressed herself, "white as statues." The left nostril could not be stimulated by the most acrid substances. Neither snuff nor ammonia produced the slightest impression on the Schneiderian membrane, nor could any irritant excite an effort to sneeze, although the sense of smell remained unimpaired. The tongue and fauces on the affected side were also perfectly insensible to touch or taste. A little acetic acid was placed on the tongue, but she could neither detect its quality nor even perceive its presence. She always masticated her food on the healthy side. During this process she often injured unconsciously the other side with her teeth, which were likewise utterly deprived of sensation, and small particles of food frequently lodged at the left angle of the mouth, without her being aware of it. Latterly deglutition became extremely difficult; solid aliments required to be pushed over the root of the tongue, and liquids frequently returned unperceived by her from the left side of the mouth. She at length became slightly deaf in the left ear. For a long time previous to her death a wasting of the left temporal muscle was observed, producing the appearance of a protuberance in the situation of the temporal ridge of the frontal bone. A few days before her death a perceptible alteration was taking place in the structure of the diseased eye, which was probably occasioned by flies, and other foreign substances, of whose presence she was unconscious, and which caused a slight inflammation of the external membranes. The pain which attended these symptoms was exceedingly acute, and almost without intermission day or night, until, after two years of the most agonizing suffering, she died August 27, 1833

During the treatment of this case none of the remedies suggested afforded any relief, although I had the advantage of consulting, in succession, Dr. James Johnson, Dr. Roget, Sir Benjamin Brodie, and Sir Charles Bell.

Post-mortem Examination.—The head was well formed, the pia mater very vascular, and a small portion of coagulated lymph was found between this membrane and the arachnoid. The lateral ventricles were full of serous fluid. The foramen of Monro unusually large. The plexus choroides were somewhat displaced. On raising the anterior lobes of the brain, a large tumor was seen occupying the left cerebral fossa of the sphenoid and temporal bones, to which it was firmly attached, completely obliterating the foramina rotundum, ovale, and the greater part of the foramen lacerum anterius. It extended inwards to the sella turcica, pushing up the optic nerve, which it had slightly flattened. It rested posteriorly on the superior petrosal sinus and pons varolii, where ulceration had taken place. The remaining portion of the brain appeared healthy.

Remarks.—The extensive distribution of the fifth pair of nerves, its connexion with, and influence on, the senses, render its functions an object of considerable physiological interest; but the situation and primary division of its trunk within the skull, render any experiments on it difficult or impossible, without endangering life. In the case just related the whole of the fifth nerve was completely destroyed, whilst both the eye and the nostrils of that side had lost their sense of touch, retaining the faculties of vision and smelling, but in the tongue both the senses of touch and taste were extinguished. It rarely happens that this nerve is destroyed by disease, without involving the surrounding structures, of which insanity is not unfrequently the result. The intellectual powers were, however, unimpaired, and the patient was able to give very accurate descriptions of her feelings. It is probable that the obliquity of the eye was occasioned by the sixth, or abductor nerve, having been involved in the disease; the partial deafness which ultimately occurred by a similar affection of the portio mollis of the seventh pair, and the loss of sensibility to colour, by the compressed and flattened state of the optic nerve. The wasting of the temporal muscle was a natural consequence of its diminished action, mastication having been for some time performed on the opposite side. The eighth pair of nerves lying at some distance from the seat of disease, were not implicated. The senses of touch and taste, which in this case were quite abolished on the left side, cannot therefore be ascribed to the glosso-pharyngeal nerve, which was uninjured, but must depend on the trigeminal, which was obliterated.

I am, sir,
Your obedient servant,
John Bishop.

38, Bernard-Street,
Russell-Square, Nov. 25, 1835.

P.S. The above case does not appear to accord with the views of Mr. Noble, contained in a recent number of your journal, the common sensibility of the tongue having been extinguished with the senses of taste and touch.

SEQUEL OF THE EXTRAORDINARY CASE OF ABSTINENCE AT AYR.

POST-MORTEM APPEARANCES.

To the Editor of the Medical Gazette.

Sir,

In the course of the judicial investigation into the accident at Kilgramie coal works, it was found necessary to disinter and inspect the body of John Brown, whose case you were so kind as to record in your journal of the 21st instant. If you think the following report of the appearances ten days after death worthy of insertion, you will much oblige, sir,

Your obedient servant,
C. F. Sloan, M.D.

Ayr, Nov. 30, 1835.

On removing the skull, the brain and its membranes presented a healthy appearance; the former, on being cut into, was found firm and fresh, as in a subject twenty-four hours dead; there were fewer marks of blood-vessels than usual; the ventricles contained fluid, just sufficient to moisten their walls; choroid plexus pale. On opening the cavity of the abdomen, the small intestine was seen lying collapsed; the stomach and large intestine moderately distended with air. The omentum had almost disappeared; it could be extended only about two inches, and was en-

tirely destitute of fat. The stomach contained two or three ounces of a greyish fluid; mucous coat entire, and healthy. At the posterior part of the cardiac extremity there was increased redness, which, however, presented no arborescence, was confined to the muscular coat, and had all the appearance of a post-mortem change; peritoneal covering natural. Intestines in every respect normal, containing some fluid resembling that in the stomach, but darker, as if mixed with coal-dust, which he might have swallowed with the water. About three inches from the anus this fluid terminated in the dark fæces which he voided during life. There was no trace of bile before arriving at this black matter, which seemed to owe part of its colour to that secretion. Liver rather small, but natural in colour and consistence. Gall-bladder distended with bile; no mechanical obstruction. Spleen dark-coloured; easily ruptured. Kidneys healthy. Bladder containing about half a pint of urine. Heart small and pale; no trace of fat. Pericardium containing about ℨj. of serum. Lungs affected with melanosis.

The following particulars, which I have learned since my first communication, may perhaps prove interesting:—Brown never suffered from his urine becoming acrid. On being brought out of the pit he was aware of the time he had been confined, having reckoned by the working of the men in another pit. He was lying several feet above the level of the place where the lamps of the workmen were extinguished.

STARVATION IN A COAL-MINE.

EIGHT MEN AND A BOY SHUT UP FOR EIGHT DAYS.

To the Editor of the Medical Gazette.

Sir,

The remarkable case of abstinence reported by Dr. Sloan in the last number but one of your journal, brought to my recollection a similar occurrence which took place in our neighbourhood upwards of twenty years back; and as the particulars were mentioned to me by one of the sufferers, I have thought that a brief narration of them would not be uninteresting to some of your readers. Although conclusions may be deduced from it somewhat similar to those arrived at by Dr. Sloan in his case, yet I think that there is evidence sufficient to prove that the aphorism of Hippocrates is far from being true, which states that "when a person in health abstains from food for seven days, even though he received nourishment at the end of that period, he never survives."

You would oblige me by correcting a mistake which has inadvertently crept into the remarks suggested by my case of hydrophobia, as it completely perverts the idea I intended to convey. In page 269, line 27 of the first column, *instead of* "a measure would have been altogether unjustifiable," *read*, "a measure would *not* have been altogether unjustifiable."—I am, sir,

Your obedient servant,

Charles Thornhill.

Darlaston, Staffordshire, Dec. 2, 1835.

John Taylor, ætatis 45, with seventeen others, on the 10th of August, 1813, went to work as usual in one of the pits of the Moorcroft colliery, belonging to Sir Joseph Scott, Bart. They descended the shaft at about six in the morning, and had been at work little more than an hour, when a large piece of rock fell from the roof into one of the avenues leading to the gateway, and almost completely blocked up the road. The lump of rock, together with the sand which accompanied its fall, was several tons in weight; and the men experienced great difficulty in making clear the passage. They had not long returned to their wonted labour when they were again alarmed by a loud rumbling noise, after which came an immense fall of sand; and they made a general movement towards the bottom of the shaft. A rapid escape was effected by those who were nearest the gateway; but the majority were less fortunate. One person, named Keeling, being a cripple, was buried beneath the falling earth; but Taylor and nine others (viz. eight men and one boy) perceived there was no hope of safety for them, and accordingly retreated into one of the side passages, where they were shut up for the space of *eight days*.

The avenue in which they were confined was about 30 yards long, 12 feet wide, and 7 feet high; but considering it insecure, in consequence of finding here and there large stones and heaps of sand, they explored a way into one of the old openings, about eight yards square, from which they feared to proceed lest there should be a further falling in of the sand. They had two or three candles which afforded them light for a few hours; and knowing that they could not be released from their situation unless a new gateway, parallel with the old one, were driven, and feeling assured that their friends would make this effort, they commenced excavating from within in the most probable, and, as it providentially happened, in the right direction; they actually succeeded, by working alternately, in making a narrow passage through the solid rock to the distance of several yards. They were provided with no kind of food; and the only support within their reach was a little water which constantly dropped from the roof, and which they partook of by stooping down and licking up from the furrows that had been made by their feet in the sandy floor. One man had about half an ounce of tobacco, but he could not prevail upon any of his companions to join him in the use of it.

No complaint of hunger fell from the lips of any except the boy, who was heard to cry several times; but they were all troubled with a sense of sickness, and with excessive thirst. Taylor states that he made water freely and regularly, though his bowels were not acted upon at all during his confinement; but that some of the others had one or more dejections.

After the first two or three days they suffered much from cold, and having on no clothing except their breeches, shoes, and stockings, they sat in a circle close to each other, in order to keep up animal heat. Taylor was so benumbed in his lower extremities, that at length he could not raise himself up without assistance; the rest also complained of numbness, but were able to move about at pleasure. During the whole period Taylor slept but once, though the others were sleeping and snoring nearly all the latter part of the time. They were all troubled with ocular delusions, which evidently arose from their physical debility and want of sustenance.

They heard the men at work for their release a day or two before they were emancipated from their prison-house; and they made frequent signals with the pike to encourage them to proceed more briskly in their labour. By the morning of the eighth day the miners had driven a fresh gateway through the solid coal, which was upwards of 120 yards in length, and they reached the sufferers at about mid-day. The air was only allowed to enter at first by a small aperture, lest there should be any accumulation of hydrogen gas, and a consequent explosion.

A small quantity of gruel was portioned out to each, and repeated two or three times in as many hours; and having been furnished with a complete change of warm linen, they were wrapped in blankets, brought up the shaft, and conveyed to each of their homes in a close carriage. Their weakness was excessive, and they were confined to their beds for several days. They were allowed nothing but gruel for the first two days; afterwards a little light pudding and broth; and on the sixth day they were supplied with a due proportion of porter.

The whole of the sufferers are at the present time living in the enjoyment of tolerable health, with the exception of the youth, who was burnt to death in the collieries about twelve months ago.

OBSERVATIONS AND RESEARCHES

ON

A NEW METHOD OF CURING CANCER.

By Alexander Ure, M.D., M.R.C.S.

Late House-Surgeon to the Royal Infirmary at Glasgow.

The chloride of zinc has hitherto been turned to little or no account by the medical world. Very recently, however, Dr. Canquoin, of Paris, has published some interesting papers, pointing out its peculiar characteristic properties, and the manner of applying it with skill and apparent success in many cancerous affections.

His first memoir on the subject was presented to the Academy of Medicine of Paris on the 24th November, 1834. It contained a very general and some-

what enigmatic account of his method. He states, that it was as far back as the year 1824 he discovered the valuable caustic properties of the chloride of zinc, and then thought it might be applied, with safety and advantage, to the treatment of cancer.

In a supplementary memoir* just published by him, which has been forwarded to me by my kind correspondent Dr. Donnellan, of Paris, Dr. Canquoin has fully communicated the principles of his plan of treatment, and has frankly divulged his methods of preparing and applying this chemical agent in the cure of a disease which has heretofore baffled all the resources of the healing art. This publication details a great variety of cancerous cases, where the chloride of zinc has been applied with perfect success. He, however, cautions the profession that practice alone can guide the surgeon in its judicious application, and that, without minute study and discrimination, it may prove inefficacious, or even prejudical. Hence a failure in unskilful hands ought to be no reason for regarding the method with distrust.

Dr. Canquoin has shown that the chloride of zinc, by itself, is an unmanageable application, but that certain combinations of it with other substances furnish a caustic which may be advantageously employed in those cases of cancerous degeneration in which surgical operation affords no hopes of relief, and arsenic, the medicine usually employed, is fraught with no little danger.

The superiority of this phagedenic paste (for so the preparation may be justly named) over every other caustic, consists in its susceptibility of being applied over very extensive surfaces without any risk of injury from absorption, and in its being available wherever the surgeon's hand can reach. The depth to which it will corrode the morbid texture can always be estimated beforehand; its action is unfailing; the separation of the eschar is prompt; and it imparts an excellent character to the sore, and soundness to the suppuration. The favourable modification of the tissues, the rapidity with which cicatrization follows, and the mildness of the general phenomena that accompany its action, are additional recommendations.

To the reproaches urged against him, of having so long carried on, in a clandestine manner, the treatment of one of the most grievous ills that flesh is heir to, he ingenuously replies, that, as he was fully persuaded of arriving at the knowledge of a certain means of destroying cancerous tumors, which should altogether supersede the employment of arsenic, the sole remedy in which any reliance had been hitherto placed, but of whose fatal effects an example had occurred in his own practice, he deemed it his duty to determine with precision its efficiency by a sufficient variety of well-established cures, before submitting it to the tribunal of the public. Thus supported by uncontrovertible evidence, he would be able to conquer incredulity and disarm malevolence.

Such, indeed, he foresaw to be the only proper course to pursue, in order to secure to himself the honour of an invention that must be regarded as a most valuable contribution to science. He was conscious that, had he published his method in a less mature state, he would have been exposed on all hands to have had his plans cavilled at, and possibly placed in jeopardy, by individuals more actuated by jealousy than the love of professional improvement. The injudicious experiments of such persons might tend to impugn the veracity of his results, and compromise the introduction of a practice fraught with eminent service to the healing art.

The leading proposition enunciated in his first memoir, is that to cure a cancerous affection, the object is not merely to destroy the diseased part, but at the same time to modify more or less profoundly the abnormal vitality of the subjacent tissues; failing which, the cancer will be reproduced. This twofold result may be obtained by means of the arsenical preparations and the chloride of antimony; but the impossibility of foretelling, in every case, whether the former might not be productive of fatal consequences, and the violent constitutional disturbances, such as the syncope, intermittence of the pulse, vomiting, alvine dejections, &c. which the latter has frequently occasioned when applied over a wide surface, have led prudent surgeons to abandon their employment. An unobjectionable substitute for them has been found in the chloride of zinc,

* Mémoire sur un Nouveau Mode de Traitement des Affections Cancéreuses, par Dr. Canquoin. Paris, 1835.

as it fulfils the above indications, and is free from the serious inconveniences involved in their use. The rapid deliquescence of this chloride formed the main obstacle to its application. By rendering it extremely difficult to manage, and by causing its conversion into a hydrochlorate, impaired its power. When used alone, in the form of small fragments or in powder, it was equally impossible to set limits to its operation, or to define the injury which might accrue from its application. To obviate these evils, Dr. C. invented a paste, formed by mixing it with a certain portion of gum, or, what is still better, flour; a mixture perfectly adapted for the purpose, eroding the tissues from half a line to two inches in depth, according to the thickness given to the layer employed and to the prolongation of its contact with the diseased surface, and which never extends its action beyond the space it covers. Thus is its operation, both as to superficial extent and profundity, most entirely under the control of the surgeon.

Chemists offer the three following modes of preparing the chloride of zinc, which I have made the subject of comparative experiments:—

1st, The neutral solution of zinc in muriatic acid may be evaporated to dryness, and fused. Or it may be obtained, 2dly, By distilling in a retort a mixture of one part of zinc with four of corrosive sublimate. Or, 3dly, by exposing to a strong heat, in an earthen retort, a mixture of six parts of decrepitated sea-salt with seven of dry sulphate of zinc; this process requires a red heat to separate the chloride by double decomposition. The product of distillation is of a greyish-white colour, translucent like wax; it enters into fusion a little above 212° Fahr., and becomes, on cooling, at first viscous, then solid.

The only notice recorded of its habitudes with organic matter, is the single fact which Black has stated, of its forming with a concentrated solution of glue a substitute for birdlime, preferable to the ordinary birdlime, in so far as it does not dry up, and may be washed off with water. The following facts have occurred in my experiments:—

When a few drops of a strong solution of the muriate of zinc are added to the albumen of the egg, a white viscid compound is formed, which, when put into water, falls to the bottom, and remains undissolved. A layer of this substance closely resembles the eschar following the application of the phagedenic paste to an ulcerated surface; and it dries in the air into a brittle, horny mass.

The solution of muriate of zinc is a good test of albumen, though not so delicate as that of corrosive sublimate.

A single drop of it produces cloudiness in a dilute solution of gelatine.

With serum of blood it forms a viscid cream-coloured compound, analogous to that with white of egg. The liquid expressed from serum of blood coagulated by heat, becomes turbid on the addition of the muriatic solution.

A portion of the crassamentum, previously washed in distilled water, and then macerated in a solution of one part of the salt to ten of water, acquires in the course of some hours a firm coriaceous consistence and aspect, not unlike hepatized lung, or spleen that had been for a while immersed in the antiseptic saline solutions of the anatomist.

The preceding results may serve in some measure to illustrate its action on the living tissue. Chloride of zinc, either by itself or in the pasty form proposed by Dr. Canquoin, applied to an ulcerated surface or portion of the chorion, stripped of its epidermic covering, constitutes with the organic texture, replete in albumino-gelatinous matter, a white inanimate crust or eschar. The great affinity of the chloride for albumen, may in some measure account for its energetic action on scirrhous and other morbid formations in which that principle predominates. M. Foy, in an elaborate analysis, has shown that scirrhus contains 42, and encephaloid tissue no less than 47 per cent. of albumen *. From seven to eight hours are requisite for effecting this change. In the layer thus acted upon, the chloride still retains some of its primitive energy, and modifies the subjacent parts, causing them at last to detach the slough. The chloride applied to the surface of foul cancerous sores, will instantaneously effect the decomposition of the carbonate and hydrosulphuret of ammonia, which Morin has ascertained to exist in the sanies which they secrete,

* Archives générales de Médecine, tom. xvii. p. 185.

and to whose presence its fœtor is in all probability owing. The renovated surface, after the separations of the slough, ceases to generate these morbid products.

This seems a probable way of explaining its physiological agency, and one, moreover, equally applicable to all analogous escharotics.

The following is a summary view of its effects, compared with other caustics:—

The painful sensation produced by chloride of zinc usually ceases in twenty-four hours; whereas that excited by arsenious acid, sulphate of copper, or chloride of antimony, commonly continues for two days. In the former case the eschar produced is white, very firm, and varies in thickness according to circumstances. The ordinary time required for its separation, according to Canquoin, is from eight to twelve days, but I have seen it completed in a shorter time. With most other caustics, from twenty-five to thirty days elapse before the sloughs are entirely removed.

Besides the pain, each caustic, after its application, gives rise to certain general phenomena, such as a local tumefaction, more or less erysipelatous in its nature, with discharge of thin fluid serum. After fused potash, and especially arsenic, these appearances are very conspicuous; whereas with the chloride of zinc they are very slight.

A degree of fever is by no means an unfrequent occurrence after its application, but that is common to arsenic, and, indeed, every other caustic, when largely applied.

Dr. Canquoin states, that the chloride of zinc, in addition to its utility in the treatment of cancer, may advantageously serve as a substitute for moxa, and as a useful means of cauterization in scirrhous affections of the neck of the uterus, and caries. I observe it has likewise been employed with success by Dr. Hanke, of Breslau, in cases of nævus maternus, fungus hæmatodes, malignant pustule, and syphilitic ulceration with a carcinomatous appearance. Dr. H., it may be remarked, employs the chloride in powder, and tries to prevent its spreading by a covering of adhesive plaister.

It now remains to notice Dr. Canquoin's manner of preparing the phagedenic paste—the mode of its application, with certain peculiarities to be attended to according to circumstances—the cases in which benefit is to be expected from its employment—and finally, the appropriate internal treatment to be observed.

[To be continued.]

SOME REMARKS

ON THE

NERVOUS SYSTEM OF INSECTS.

To the Editor of the Medical Gazette.

SIR,

I TRUST that Mr. Roberton will excuse the liberty I take in venturing to suggest some little anatomical inaccuracies in the following paragraph of his second letter on Dr. Elliotson's views respecting life and mind.

"Third—'Superiority of mind in the animal creation is exactly commensurate with superiority of brain.' This is an incautious assertion, if by 'superiority' is to be understood largeness, or some particular form of the head, since these are at present points confessedly of doubtful disputation, and likely so to continue. Besides, Dr. Elliotson is well aware that insects, the most reasoning, perhaps, of all the inferior creatures, have properly no brain, a slight enlargement of the upper extremity of the spinal marrow being all that stands for that organ."

This latter assertion, anatomy tells us, is quite unfounded: it tells us that insects have a nervous organization superior to every other tribe of invertebrate animals,—that in this respect the whole division of the Articulata is above the Mollusca,—and that the restricted modern class "Insecta" stands at the head of all. The very circumstance of Mr. Roberton's calling the ganglionic cord the spinal marrow, would elevate them to this high position.

I will, as briefly as possible, detail a mere sketch of their nervous system, with a view of partly proving these statements.

The nervous system is found in every order of the true Insecta to consist of a ganglionic nervous cord running along the abdominal surface of the body, and a supra-œsophageal nervous mass, called by Cuvier

"the brain *," and by many anatomists the cerebral ganglion †. This nervous cord consists of a varied number of ganglia, giving off lateral nervous filaments, and connected to each other by longitudinal sensitive columns. A motor tract has also been recently described by Mr. Newport ‡, passing along the dorsal surface of these columns, and giving off lateral nervous branches. There is also a minute nerve, which I have traced in the larva of the *Saturnia pavonia minor*, passing off at the angle of separation between the divided longitudinal cords connecting the fourth and fifth abdominal ganglia, and which, midway between these ganglia, divides into a right and left transverse filament, each of which had connexion with the anterior of the lateral nerves arising from the ganglia themselves. Some have considered these nerves as sympathetic, others as motor; but Mr. Newport argues, and I think very justly, that from their distribution they must be respiratory nerves.

These anatomical details, and many other collateral circumstances, would tend to show a great analogy between the ganglionic cord of insects and the spinal cord of the Vertebrata. Its situation in the body, and the relative position of the motor and sensitive columns, are different in the two groups; but a moment's reflection will render the reason for this inverted position obvious.

The cerebral ganglion is situated above the œsophagus: I have generally found it of a bilobate form, and it is connected with or produced from the first sub-œsophageal ganglion by two minute lateral commissures; from it are given off nerves both for sensation and motion, viz. to the antennæ, eyes, maxillæ, palpi, &c.; a remarkable single nerve also has its origin from it, which passes backwards along the dorsal surface of the œsophagus, giving off branching filaments to the stomach: this is the recurrent nerve of Lyonnet. It is considered by Straus Durckheim as the rudiments of a sympathetic system §, and by Mr. Newport as the analogue of the par vagum. The form of this cerebral ganglion I have found very remarkable in the bee tribe. It was of immense proportional size; it had a distinctly bilobate appearance; a deep fissure traversed it transversely; from its anterior part were given off two nerves, which passed forwards to the base of the antennæ, and had their origin marked by a very distinct conical-shaped ganglionic enlargement. Surely this cerebral ganglion (the rudimentary optic lobes of the inferior Vertebrata, the subsequent tubercula quadrigemina of the Mammalia), cannot be considered "as a slight enlargement of the upper extremity of the spinal marrow." It is singular that Mr. Roberton should admit the importance of the ganglionic cord, by calling it the spinal marrow, and destroy the importance of the cerebral ganglion, by not considering it analogous to a brain.

Thus I have endeavoured to show the existence of motor and sensitive columns in the spinal cord, a respiratory system of nerves, a par vagum, a remarkably developed cerebral ganglion, and consequently a highly-developed nervous organization generally. I refrain from entering more minutely into these subjects, as they will be detailed at greater length on a future occasion.

I remain, sir,
Your most obedient servant,
JOHN ANDERSON.

George Street, Richmond,

ON THE NATURE OF THE NERVOUS INFLUENCE;

IN REPLY TO DR. WILLIAMS.

To the Editor of the Medical Gazette.

SIR,

ALTHOUGH a reference to the opinions of others is still a favourite argument with Dr. Williams, if such it can be called, he has changed his mode of reply; but I am sure he will acknowledge not for the better, when he finds he has taken pains to oppose opinions which I never entertained, and some of which I have put myself to much trouble to refute. Before proceeding farther, however, I may remark that I cannot see how what he now says respecting his quotation from Dr. Alison's work af-

fects my observation on what he said before, farther than that it confines it to the writers he enumerates, who, having paid particular attention to the subject, may surely be allowed to be as well acquainted as others with the physiological knowledge of Haller. The words to which I replied were, "that the province of the nervous system was more accurately understood by Haller."

In the commencement of the present discussion, I observed that one of the inconveniences I had laboured under, was that from the protracted nature of the investigation in which I had been engaged, and the number of publications among which its results are distributed--namely, besides my Inquiry into the Laws of the Vital Functions, eleven papers in the Philosophical Transactions, during the course of twenty years—those who have replied to any one part have often been unacquainted with others with which that part was immediately connected. Dr. Williams's present reply is a good illustration of this observation.

I have never maintained that after the removal of the brain and spinal marrow the capillaries would not gradually lose their power. How could it be otherwise? I only stated that the animal being properly prepared, the removal of the brain and spinal marrow produces no immediate effect whatever on the circulation, either with respect to the heart or vessels; proving that the effect of their removal on these organs is not direct, that the power of the latter does not immediately depend on the former organs, because in that case their action would have immediately ceased, the only object I had in view; which Dr. Williams evidently loses sight of when he speaks of their action having been observed for a longer time than I had observed it.

Dr. Williams's reply to what I say of Chossat's experiments, is the consequence of his not being aware that the facts I had stated show that the destruction of the semilunar ganglion must necessarily produce similar effects with that of a great portion of the brain or spinal marrow. Had Dr. Williams been acquainted with my opinions, he would have seen nothing at variance with them in any of the experiments of Chossat to which he refers.

With respect to the division of the spinal marrow, so far from conceiving that it could affect the maintenance of the temperature, as Dr. Williams intimates, I have been at much pains to prove that neither this nor any other vital function of the spinal marrow is affected by dividing it, and to explain why this is necessarily the case, except in as far as relates to the disturbance caused by the minute portion of that organ necessarily bruised in making the division, which certainly can have no sensible effect on the temperature, although I could trace its slight effect on the function of the stomach. I have already had occasion to allude to this subject in the present discussion. Enough has been said to show how much Dr. Williams has mistaken my opinions, and I shall only add a few observations, of a different kind, on the more essential parts of his reply.

I THINK Dr. Williams will at once see that his reference to certain properties of electricity, as they appear in the inanimate world, can have no weight in the present discussion, since one of the fundamental principles in all I have said is, that its properties are modified by those of life, under the influence of which it operates in the living animal, as it operates in the magnet under the influence of the properties peculiar to it. If Dr. Williams will attempt to apply his mode of reasoning to the electricity of the magnet, he will perceive how inapplicable it must necessarily be to that of the living animal. Does not terrestrial electricity uniformly affect the common electrometer? Yet the electricity peculiar to electric animals, respecting the nature of which there is no difference of opinion, produces no effect on it. The manner in which electricity is modified by the powers of the living animal, is a question altogether different from that before us.

Such objections cannot at all affect the inference from the fact, that electricity performs all the functions of the nervous influence; for it does not, as Dr. Williams states, "affect certain vital functions in a definite manner," but performs all the functions of the nervous influence as perfectly as they are performed by that influence itself, and that during the whole remaining life of the animal. Both the function of the stomach and that of the lungs are as well performed, and their healthy structure as perfectly maintained, as

while the nervous influence remains, the structure of the latter being such as admits of our judging even of its slight deviations.

When the nervous influence is withdrawn, without the substitution of electricity, the secretion of gastric juice ceases, and the lungs gradually become so obstructed as to be the immediate cause of death, their structure in many parts being wholly destroyed. When electricity is substituted for the nervous influence, as we cannot apply it in the way in which it is applied by nature, it at length (that is, long after their structure would have been impaired, had electricity not been employed) excites inflammation, and the animal dies of inflammation of the lungs, but without change of structure, precisely as it would do were the same degree of voltaic electricity, or any other powerful cause of irritation, affecting the lungs, applied while the nervous influence is unimpaired. In short, as far as the functions of the nervous influence are concerned, the animal is in all respects in the same state as if that influence had been entire.

None of the circumstances mentioned by Dr. Williams can at all affect the inference from these facts, of which I think Dr. Williams will be aware when he considers the subject more at leisure, —an inference which he will find it impossible to get rid of, except by disproving the facts on which it is founded. Let him show how this inference may be refuted, and he will do more respecting the question before us, than by writing volumes in the style of his present communications; for whatever else he does, this he must do, not only in order to disprove my position, but even to render it doubtful, because the ground I take is, that while the facts remain, the inference is unavoidable. It is sufficient to refute all I have said, to show that such is not the case.

This reduces the discussion to a very narrow compass; all else is superfluous, because it can be of no avail. Nothing but this is required, and for this nothing can be substituted. If this cannot be done, my inference must necessarily be regarded as established.

If it be our sole aim to arrive at truth, we must keep the attention steadily directed to the point on which the discussion rests. All deviation from it tends only to perplex the reader, and consequently, as I have already had occasion to remark, to obscure the truth; in arriving at which "the latest and best authority," unless it be proved to be a correct authority, will give us no assistance.

With respect to Professor Faraday's researches, which Dr. Williams so justly commends, I believe that he himself in no degree views them as in opposition to my opinion. If they had been so, I presume he would not have taken the trouble, as he was so good as to do at my request, to try to cause the electric nature of the nervous influence to become sensible to the very delicate tests discovered by him; and I am permitted by him to repeat the spirit of the observation he made on the failure of the attempt. He said, we have now failed, but I have great expectation we shall sooner or later succeed; for, from the time that it was shown that electricity could perform the functions of the nervous influence, I have had no doubt of their very close relation, and probably as effects of one common cause. And, indeed, his great knowledge of the subject of electricity enabled him to state the cause of our failure, without having recourse to the incredible supposition that there are two distinct principles of action; one of which is capable of all the functions of the other.

I believe it will not be necessary to say much more of Dr. Williams's observations on the nature of electricity or chemical action. He forgets that carbon and oxygen will not combine by mere juxtaposition, either in the living blood or the laboratory of the chemist. In the latter they may be made to combine by the electric power; in the former, as appears from facts I have stated, by the nervous influence; so that here also we see electricity possessing the same property as that influence.

I shall only add, that in this long discussion I have obtained no reply to either of the only two questions I put to Dr. Williams—namely, seeing that voltaic electricity performs all the functions of the nervous influence, can they be different principles? — and seeing that the nervous influence is capable of existing in other textures than that of the nervous system, can it be a vital power, properly so called?

As, in all he has written, he makes no

reply to either of these questions, I am left to conclude that no other replies but those I have given can be made.

Had the style of Dr. Williams's papers been as well directed to the points in discussion, as it has been gentlemanlike, our discussion would have been more useful. No degree of ingenuity can avail in opposition to simple matter of fact. A reply, to be of any weight, must be direct, and to the facts. The want of such a reply in the present instance, may be regarded as a presumption of its impossibility; because, by a man of Dr. Williams's talents, it will always be preferred when it is possible.

As in my last communication I stated the grounds of my opinions respecting the nature of the different powers of the animal body, I shall in a communication next week state my opinions respecting the sources of these powers, and the relation they bear to each other. These two communications will comprehend the general results of all I have done on the subject, and may at least be the means of preventing opinions being attributed to me which I not only never entertained, but put myself to much trouble to refute.

I am, sir,
Your obedient servant,
A. P. W. Philip.

FAULTY and DEFECTIVE SYSTEM OF OUR HOSPITALS

IN RESPECT TO NURSES AND SISTERS.

To the Editor of the Medical Gazette.

Sir,

It is a constant theme of well-grounded complaint among medical men, that their treatment of disease is frequently frustrated by the ignorance or carelessness of the nurse who superintends the patient during their absence. Every practitioner can call to mind numerous instances of prolonged cases and untoward terminations, justly attributable to this cause. My object is not merely to deplore a state of things so generally acknowledged, but likewise to point out what I consider one fertile source of the mischief.

When we reflect upon the skill, discretion, and kindness, which should form the attributes of a good nurse, we readily admit that the knowledge of her art cannot be intuitive, but must result from careful training and long experience among the sick. I should have imagined that our large hospitals would have formed the best schools for instructing females in the important duties of nursing the sick; but so faulty are their arrangements in this particular, however admirable in many others, that the matter of surprise is, that a good nurse should ever be found within their walls. My observations apply especially to St. Bartholomew's, at which alone I have had personal opportunities of observing the injurious effects of the system; but I believe the same remarks will more or less extend to most of the others.

In the first place, the *salaries* are far too small to induce efficient and respectable females to undertake the duties longer than sheer necessity compels them. The *sisters* even, upon whom the whole responsibility of the ward devolves, receive so miserable a pittance that it has excited the surprise of many to find, occasionally, very respectable women in the employment, while it affords a sufficient reason for the carelessness and ignorance of the majority. But the inferior *nurses*, upon whom many of the comforts of the patients mainly depend, are so wretchedly remunerated, that even bare subsistence seems to me hardly possible*. I will ask, can a greater reproach attach to these wealthy institutions than this niggardly proceeding—offering, as it does, every temptation to extortion from the patients or their friends?

Next, *their duties are by far too onerous* to permit them to pay proper attention to the patients. This remark applies only to the nurses, for I do not consider that if the sisters were better paid they are too much worked. The nurses (two in number for each ward) are required to sit up alternate nights, and have to undergo various household employment in the wards during the days; and no doubt, owing to their

---

* The sisters receive from 14*s*. to 16*s*. per week, and the nurses 7*s*.; and I believe in the accident-wards rather more. The nurses also have a small portion of food allowed them, but far short of sufficient for subsistence.

miserable remuneration, would be glad to do any thing elsewhere to increase their pittance. I do not constitute myself a judge of the precise duties each nurse ought to be called upon to perform, but I can speak from experience, that, under the present arrangement, they have too much to do. Many nights have I seen the night-nurse, exhausted from her previous labours, quietly enjoying that repose in which she stood so much in need of, heedless of the cry of pain or the call of thirst—forgetful of the administration of medicine, or the renewal of some necessary application; and is not the night season that in which her duties are most urgently called for, whether we consider the usual exacerbation of diseases at that period, or the sleepiness of all around, except those who require her assistance? So impressed was I with the truth of what I have stated, that during my attendance at the hospital, when I had a patient whose case urgently demanded attention during the night, I felt it always my duty to remain with him, rather than leave him to the care of one of these exhausted females. Another evil of great magnitude, resulting from this system of over-working, is the engendering of disease, and the habit these women acquire of stimulating themselves to wakefulness by ardent spirits. In several cases I have distinctly traced serious illnesses of the nurses to excessive exertion and want of rest; and have seen diseases fatal, or terminate most seriously, from these causes. A few years since, a gentleman who was dressing with me, united with me in presenting to the Governors a memorial of the wretched state in which the nurses were placed by the arrangements of the hospital, and of the magnitude of the evils which must result thence, both to themselves and the patients under their charge. We received no reply, nor do I perceive any considerable amelioration has taken place. It seems to me, in order to be adequate to their duties, the attention of the nurses should be *solely confined to the patients*, and that measures should be taken to *ensure them that rest* which they are otherwise obliged to snatch at the expense of the patient's interest.

Lastly, the mode of their *appointment*, *removal*, and *promotion*, is very faulty; being entirely independent of the medical officers, and vested in the hands of the matron, or steward; who, of course, are perfectly inadequate to judge of their capabilities. The consequence of this system is, that many females are placed in the office who are perfectly unfit, and that several whose conduct is praiseworthy do not meet with the encouragement they deserve. I consider the apathy the medical officers display upon this point is highly discreditable, and perfectly inconsistent with the anxiety they so often display for the welfare of their patients. The appointment of nurses and sisters should rest with them, as should their dismissal or promotion. If this were the case we should not see (as I have done) inefficient, idle, and frequently drunken women, maintained in their places in spite of their unfitness; while those whose conduct has merited approval have been suffered to remain unnoticed. The reason is plain; the matron, or steward, can be no judges of the matter, and must often be the victims of intrigue and deceit. In connexion with this subject, I think it will hardly be believed that these females falling ill, in the service of the institution, so far from being especially provided for during their illness, run great risk, upon their recovery, of finding themselves placeless.

I think I may say the above facts are worthy the attention of our hospital medical officers, and need advance no argument to prove that the existence of this state of things must be hurtful to the reputation and interest of the surgeon himself, and much more so to the comfort and well-doing of the patient, who (in the hospital especially), removed from the soothing and endearing attention of his friends, requires increased care, and feels with more poignancy neglect or unkindness.

It is no reply to me to tell me, that, notwithstanding, many of the hospital nurses are excellent; I have frequently borne witness to the fact: but they are so in spite of the system, not in consequence of it.

In applying these observations to the subject with which I commenced this letter, I ask, if our hospitals are not to furnish us with a supply of well-schooled nurses, where are we to look for it?—and I also ask, do they fulfil this important office? True it is, in private practice, we daily witness instances of the friends of the patient devoting themselves with unceasing assi-

duity to his interest; but, however pleasing this spectacle is to the philanthropist, the medical man knows well the evils too often resulting from well-meaning but ill-timed acts of kindness, to trust implicitly to this source. It is also true that we meet with many excellent hired nurses; but yet these are so few in number, and their terms, in consequence, so exorbitant, as to place them beyond the reach of the middling and working classes, where their services are most required. I believe that if the system of nursing were properly regulated at our hospitals, these would furnish us with women in whom we could trust, and who would be content to give their services for a moderate remuneration.

I trust, sir, you will distinguish the motives which actuate me in making this communication, from that spirit of indiscriminate opposition which is often indulged in for the mere sake of finding fault. I believe I have here pointed out one error in the system of hospital management, the rectifying of which would confer benefit upon the parties concerned, as also upon our profession and the public at large.—I am, sir,

Yours obediently,

John Chatto.

Burton Crescent, Nov. 12, 1835.

EFFICACY OF IODINE IN SECONDARY SYPHILIS.

To the Editor of the Medical Gazette.

Sir,

Like most preparations used medicinally, iodine has its friends as well as enemies. That the virtues of this medicine have been in some degree overrated, cannot be disputed by those who have good opportunities of testing its properties. Dr. Addison, our much respected President of the Westminster Medical Society, stated, a few weeks back, during a discussion on this subject, that the physicians of the hospital with which he is professionally associated, had tried the preparations of iodine in all the diseases in which this medicine is supposed to exert a peculiar efficacy, and the result of their experience was to the effect that iodine was all but *inert*. Dr. Elliotson states, as the result of his experience, that iodine is a valuable remedial agent. How are we to reconcile the conflicting opinions (both said to be based on *facts*) of two such eminent physicians? Is it attributable to a difference in the *quality* of the drug used? Dr. Addison says the iodine he used was unadulterated; it was detected in the urine of the patients to whom it was administered. Are we to account for this juxta-position of opinion by supposing that the iodine, in the cases in which Dr. Addison made trial of it, underwent some modification, owing to idiosyncrasy of constitution? If he tried it in a variety of cases, no such inference could be drawn.

In questions involving *theoretical* points we need not feel surprised that great dissimilarity of opinion should exist; but it certainly is, particularly to non-professional individuals, singular, that, on questions purely of *fact*, medical men should come to such opposite conclusions. Perhaps we are justified in believing that both Dr. Elliotson and Dr. Addison err in entertaining *extreme* opinions; Dr. E, in recommending an almost (I was going to say) indiscriminate use of iodine, and Dr. Addison, in denouncing the medicine as inert. Truth generally lies between extremes, and I think in this matter, such is the case. In the course of my practice for the last few years, I have given iodine a fair trial; the result has not realized my anticipations. It certainly is beneficial in many cases; but in a variety of affections in which it is said to be extremely efficacious, I have found it of no benefit. In secondary syphilis I have found this medicine extremely serviceable. I have had under my care a considerable number of cases of this description, in all of which the disease was either cured or considerably alleviated by the exhibition of the hydriodate of potash. In one case which I attended lately, in conjunction with an eminent physician, in which nearly the whole of the body, with the exception of the face, was covered by a venereal eruption, evidently the consequence of the primary disease not having been attacked with mercury, a decided cure was established in three weeks by the combined administration of the hydriodate of potash and sarsaparilla. In the hard periosteal node, the result of my experience coincides

with that of Dr. Williams; I have found the hydriodate of potash attended with decided relief in such cases. Without entering into a minute detail of cases, I may observe that the hydriodate of potash will be found a valuable remedial agent in secondary syphilitic affections. I have not confined my observations to cases which have come under my own care, but I have, with a view to the publication of a treatise on the efficacy of the preparations of iodine in secondary syphilis, carefully observed the practice of others in this disease, and I feel fully warranted in classing iodine amongst our most useful therapeutic agents. I think I may do so without incurring the risk of having imputed to me the charge of entertaining an extreme opinion as to the remedial efficacy of this drug. I do not wish it to be discarded, neither do I wish to see the confidence of the profession in the medicine removed, by its being overvalued. Perhaps I was wrong in saying that Dr. Elliotson recommended an indiscriminate use of iodine. I know, having had the honour of being his pupil, that he has a decided *penchant* for this medicine. Lovers, they tell us, are blind to the faults of their mistresses; perhaps a similar influence is exerted on Dr. Elliotson's mind with reference to the virtues of iodine.

From what I have said, I would not wish it to be inferred that I question the accuracy of Dr. Elliotson's facts,—I believe him to possess a mind capable of close and attentive observation, and power of reasoning equalled by few in the profession.

Should the above observations deserve a corner in your valuable journal, you will oblige me by their insertion.

I am, sir,
Your obedient servant,
FORBES WINSLOW,
Member of the Royal College of Surgeons, London, &c. &c.

33, St. Martin's-le-Grand,
Nov. 29, 1835.

I saw a case, a few weeks back, in which iodine brought on salivation. I am not aware that such an effect has been attributed to the use of this medicine.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri: potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

MEANS OF ESCAPING SUFFOCATION IN HOUSES ON FIRE.

WHENEVER some frightful calamity by fire has taken place—like that lately at Hatfield House, or in Tottenham-court-road, where so many lives were lost—the public are amused for a time with the speculations of ingenious persons who propose various methods for escape; but the interest soon passes off—not to be revived again until after the next conflagration.

The subject, perhaps, is distasteful to most people: the mind naturally revolts from the contemplation of the terrible mischiefs done by fire, and both ears and eyes are shut against the possibility of fatal accidents, and the suggestion of measures of safety. A dream of security is enjoyed, till destruction itself comes upon the sleepers, and wakes them to an awful sense of their condition. The principal precaution taken by some of the most prudent members of the community scarcely goes beyond the insurance of their property, which seems to render them even more than ordinarily careless of their lives. The very frequency of dreadful fires inures them to their carelessness; and seldom is a thought entertained of how persons should act in case the devouring element should approach them.

Those who have recently been attempting to engage public attention to the subject, have scarcely gone farther than recommending certain staples and noosed ropes to be provided, in order to exchange the danger of burning for the risk of being precipitated from a window. Few or none have

recollected that often in such circumstances there are objects to be saved as valuable as, and even dearer than, life itself. When, at Hatfield House, the noble owner of the mansion, with all his retainers around him, stood aghast at the door of his mother's burning room, and none dare enter to rescue the unfortunate lady, living or dead, nobody thought of a simple expedient, by which that object might possibly have been accomplished—the simple application of a wet cloth or handkerchief to the mouth, and boldly venturing in. Unless there were absolute flame to oppose such a step, breathing in the densest smoke could be effected for a few minutes; and what good, even in that short space, might not have been done? Better still if the courageous rescuer should enter on hands and knees, with his mouth and nostrils protected in the manner just mentioned. The expedient is by no means new, however newly it may recur to the public attention; nor is it the less valuable, perhaps, for having been sometimes tried with success.

It is now about ten years since the contrivance of John Roberts, a poor miner, was the subject of general wonder and admiration. This man invented a covering for the head, with glass or talc eyes, and a tubular mouth-piece; with this he was put to the test, both in this country and in France, and under its protection could resist the most suffocating vapours of burning sulphur and resinous matters, shut up in a room for above half an hour, where no other mortal, without such a defence, could exist for half a minute. Why this valuable contrivance has not been more generally adopted we can form no conjecture, except we refer it to that apathy on the part of the public already alluded to. That it has not lost any of its original reputation, or prospect of usefulness, is shown by the Parliamentary Report on Accidents in Mines, just published. There the Safety-hood is mentioned in high terms. The following is what the Committee say:—

"Mr. Roberts produced to your Committee his safety-hood......Your Committee report with pleasure their opinion of its great value, and of the merit of the inventor. The advantages to be obtained by having the safety-hood always ready for use are by no means hypothetical: interesting proofs of what may be effected by its use have been received; and the practicability of saving life after explosions, when no hope remained, has been demonstrated*."

The history of the origin of this contrivance is curious. It is thus related by Roberts himself, in his evidence before the Parliamentary Committee:—

"Did you meet with accidents from carbonic acid gas while at Newbottle colliery?—On one occasion I had nearly met with an accident. In the shaft there were two very large furnaces to draw the foul air out, and to cause a quick current of air to circulate through the works. At this time the firemen, who took care of the furnaces, had thrown a fresh supply of fuel on them: owing to this circumstance, on descending the shaft, I was nearly suffocated. It struck me at the moment to wrap my jacket round my face: it happened to be very moist, and when I got to the bottom of the shaft I found I was very comfortable, and a sudden change had taken place in the apparent state of the air. Some time after I was thinking over the matter, and it occurred to me that the cause was the woollen, and the perspiration with which it was saturated, that preserved me in this instance. From trying further experiments in the same shaft, I found it was the woollen, which I then moistened with my bottle of water. I often used to be turning this matter over in my mind, and was led to make an apparatus to prevent accidents from suffocation, and thus enable the workmen to work, and to have the use of their hands and eyes, in an impure atmosphere†."

* Report: Accidents in Mines, p. viii.
† Ibid.: Minutes of Evidence, p. 261.

The apparatus here mentioned is the Safety-hood, for the invention of which its ingenious author was rewarded with 50 guineas and a medal by the Society of Arts, and 100*l.* by his late Majesty.

Can there be a doubt that the lives of a party mentioned in Mr. G. Stephenson's evidence would have been saved, if even one of the men were provided with a safety-hood.

"With regard to sulphuretted hydrogen gas, there was a case at Newbottle, where there were six men lost by that gas. I imagine it was that kind of gas, for the lamps did burn when the men died. There were three men working in a drift, and one of them said he felt himself unwell: it was quite a separate place from the other part of the workmen, and he thought he would go out; and the other one said he thought he was not well also, and agreed to go out: but they did not go very far when one of them said he must sit down, he could not go any further: they had a light with them, and the other man went on. An alarm was given. Mr. Hill, the viewer, happened to be at the colliery at the time, and immediately prepared to go down the pit with all the men that had any charge in the mine. I think there were five besides himself, and they could not make out the cause, as the lamps burnt, of the men stopping: but Mr. Hill said to his men, "Let us use all the caution we can in proceeding to seek these men." He desired the men, in going forward, not to speak unless they felt a change in their breathing, or any other change that they conceived was a change of the vital powers. They left guides at different places to give the alarm to the shaft, in case there was any thing amiss took place with them. They went on some distance, when at last Mr. Hill spoke and said, "I feel a ringing in my ears: do any of you feel a change?" When he spoke they all thought they felt some change: and he said, "Let us go back." They turned round to go back, and all fell. There were some of them so strong as to give the alarm to the others, and fresh men came running in, and got, I think, two out of the six brought out alive. Mr. Hill was one; he was brought out as a dead man; but he and the other man recovered; the other four that were not got out so readily all died *."

But to return to the subject of fires. The suffocating smoke in burning houses is probably by no means as deleterious as the choke damp, and other occasional gases in mines. The fumes in burning apartments must of course be of a mixed nature, according to the substances accidentally consumed, and the supply of oxygen which is present; but in general they consist of carbonic acid gas, carbonic oxide, carburetted hydrogen, &c., and always leave an interval between them and the floor, which is filled with ordinary atmospheric air. This latter interval is even present where straw, shavings, wet hay, and sulphur, have been ignited near the floor.

We have a valuable analysis, by Mr. Pepys, in which these facts are ascertained. When Roberts was introduced, by way of ordeal, into a room filled with the fumes of burning resin, sulphur, &c., and in which he remained, with free powers of locomotion—principally, indeed, occupied in stirring the fire and keeping the fuel together—he was entrusted with three bottles of mercury, which he was to empty at different altitudes from the floor, in order that, by corking the bottle immediately, specimens of the air, at the given levels, might be secured for examination. The result was, that

The air taken from the middle of the room, as to elevation, appeared to contain the largest quantity of carbonic acid, and the smallest quantity of oxygen; the following being the results of a very accurate analysis: 2 carbonic acid + 18 oxygen + 80 azote = 100*.

If the resultant compound in this case be compared with the destructive gases of mines, it will be perceived how much the balance is in favour of the fumes generated in the conflagration of houses; the more so, as in the latter case there may not often be present sulphurous acid, and the vapours given out in bituminous combustion; so that the gaseous products of burning timber, furniture, &c. may not present such for-

* Report already quoted, p. 120.

* Letter of Mr. Pepys, March 1825.

midable obstacles to respiration. The fact is, that, on correct chemical principles, the nature of the bane, as well as the antidote, are indicated and made apparent. There is no remarkable diminution of oxygen, (according to Mr. Pepys' analysis,) even where these combinations take place; and the noxious effects are chiefly owing to the smoke and vapour, and carbonic acid, with which the air of the burning apartment is loaded. Now the former may be strained, and the latter neutralized, or absorbed. In the construction of Roberts's safety-hood, both these indications are provided for: the mouth-piece consists of a flexible tube, somewhat resembling, on a small scale, an elephant's proboscis; the length is about three feet, and its lower extremity, which is bell-shaped, contains a sponge, moistened with chloruret, or cream of lime, or common water, according to circumstances, or the nature of the medium in which respiration is to be sustained. The noxious gases, on coming in contact with the sponge and its contents, are intercepted, and what air enters the tube is mechanically filtered before admission: add to this, the length of the mouth-piece, which permits the purer air to be inspired from the lower strata of the apartment, and it will readily be admitted that the contrivance is admirably adapted for the purpose for which it is designed. This was the apparatus with which the inventor not only stood the fiery and mephitic ordeal in the instances above mentioned, but thé same with which he entered the old sewer of the Bastile at Paris; which had not been cleansed for thirty-seven years, and cost two men their lives fifteen years previously, when, under the superintendence of distinguished *savans*, it was attempted to be opened.

For minor operations, and where exposure to suffocating vapours may not be requisite for above a few minutes, we understand there is a much simpler contrivance employed by Roberts; one that merely covers the mouth and nostrils with the moistened sponge, secured by wire-work. There is every reason to believe that it would be possible to move for some minutes in the midst of suffocating vapours, with the assistance of so simple an instrument: even the mere application of a wet handkerchief to the mouth and nose, affords much protection; and still more are these simple means rendered available for a number of minutes, in which great good might be done, if the adventurous individual would take the precaution to confine his breathing to the lower strata by crawling on hands and knees.

How much valuable property has been lost—how many people have been burnt to death—from the impossibility of reaching them,—those willing to venture their lives to the utmost for the rescue being ignorant of the plain facts just stated. We do not say that such accidents cannot possibly happen in future, if only the aid of the safety-hood be secured. But we think that some such apparatus ought to be at hand: if not in the possession of private individuals, at least in the keeping, and under the control, of the public authorities. Something of the sort ought surely to be kept in readiness at the police station-houses. Why the safety-hood of Roberts has not been more generally received and adopted we cannot tell; perhaps it is too dear; but this we are convinced of, that the principle on which it is constructed is a sound one. We repeat that it cannot be too generally inculcated, that the great danger of suffocating fumes in burning apartments may be in a great degree obviated by a wet handkerchief applied to the mouth and nose, (if the handkerchief be wetted with soap and water it is still better,) and by moving beneath the vapour on hands and knees.

We have already alluded to the apathy of the public in respect to the attention which a subject of this kind demands: perhaps the legislature is not less to blame for neglecting to provide for that almost infatuated indifference; and we cannot conclude without expressing our full concurrence in what we just find stated by a writer in one of the public journals (the *Times*):—"It would, perhaps," says he, "be found a difficult task to adduce many cases occurring in a town wherein life was lost by the burning of a house, which life might not have been saved if an act of Parliament had made it the duty of the public authorities to keep and to use those means for the preservation of human beings which scientific men, and even men of science, have had the fortune to devise, make known, and live to see neglected." We entirely approve of the suggestion which follows, namely, that public meetings should be immediately held, in order to urge the authorities to adopt proper measures.

DEATH OF DR. WARREN.

THIS distinguished physician died on Wednesday the 2d instant, at Worting House, near Basingstoke, in the 58th year of his age, of organic disease of the liver. Dr. Warren was elected one of the physicians to St. George's Hospital in April, 1803, an office which he held exactly thirteen years, having resigned it in the same month, 1816, before which period he had already obtained a large share of business.

Dr. Warren made no contributions to medical science of which we are aware, except a paper on Headache, which he published in the Transactions of the College of Physicians, and a case of Ossification of the Aorta, read at one of the evening meetings in Pall-Mall East. His character and conduct, however, were well calculated to support the profession to which he belonged. His sentiments were in all respects those of a gentleman; and as he was too independent not to express them when the occasion required, titled impertinence has more than once been overmastered by the caustic bitterness of his retort. His manners were peculiar, and not always pleasing, being generally cold, and sometimes abrupt. He took a prodigious quantity of snuff, and was plain and untidy in his dress—perhaps to affectation. For many years he appeared to take no more exercise than in walking from his carriage to the sick chamber, and looked much older than he really was; but he had a remarkably keen black eye, which retained its vivacity long after the effects of disease were visible on his countenance. He moved in the highest rank of his profession, and though long in indifferent health, continued to discharge the duties of a very extensive practice up to the accession of the illness which proved fatal to him.

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

BY M. ANDRAL.

From the *Gazette des Hôpitaux*, in which they are in course of publication, with his approval.

OF HYPEREMIA, OR CEREBRAL CONGESTION *.

Anatomical characters—External causes—Alimentary substances — Narcotics — Internal causes—Digestive system—Circulating system—Qualities of the blood—Respiration—Secretions—Generative apparatus—Symptoms—Congestions of the cerebrum—of the cerebellum—of the spinal cord—Treatment—Chronic congestion of the spinal marrow—Treatment.

HYPEREMIA of the brain is a common disease, which presents itself under a variety of different forms. It may attack all parts of the nervous centres, and be either partial or general. When partial, it is most common in the two hemispheres, the rest of the cerebral mass and the spinal cord remaining entire. It may happen that only one hemisphere is affected with congestion, and then one side of the body presents symptoms similar to those which attend hæmorrhage into the brain. The congestion may take place not over an entire hemisphere, but in a portion of it, and follow the established anatomical divisions, occupying, for example, the an-

* The present discourse comprises lectures 2 and 3, as delivered by the Professor.—ED. GAZ.

terior middle or posterior lobe, — a limitation analogous to that which we meet with in the inflammation of many other organs—the lungs, for instance.

In the cerebral hemispheres, as in the other parts of the nervous system, the congestion may implicate either the cineritious or cortical substance; and there are some cases in which this limitation is well defined. The congestion may be deep-seated or superficial. As the hemispheres may have general or partial congestions, so it is also with the other parts of the cerebro-spinal mass: thus we may have isolated hyperemia of the entire cerebellum, or of one of its lobes; and again, the congestion may attack only the spinal marrow, leaving the brain intact. Such are the different seats of congestion in the nervous centres. Let us now consider the lesions which we find in the dead body.

Anatomical characters.—The most marked, or even the only one, is a certain degree of redness, presenting different shades according as the congestion has more particularly affected the white or grey matter. If the white, we observe, on slicing the centre of the hemispheres, a fine mottleing of innumerably small red points. The greater the number of these points, the greater the congestion; they are particles of blood exuding from the vessels, rendered apparent by the disease. If it is the grey substance which is the seat of the congestion, we no longer observe a red mottleing, but the substance is throughout of a rose colour, occasionally heightened to a brighter tint. Along with this change of colour are other lesions: thus the meninges are often considerably injected, the large veins of the pia mater are gorged, the sinuses filled with black blood, and sometimes, when the congestion has been very intense, we may discover a little blood in the texture of the pia mater; this is a transition from congestion to hæmorrhage, only that it does not take place in the cerebral substance. We may also find in marked cases some serum within the pia mater, on the surface of the brain, or in the ventricles, and which seems to result from the obstacle to the return of the blood through the overloaded veins and sinuses; and this serum acts an important part in the production of certain symptoms.

It is necessary, however, to inquire into the circumstances occurring before death, in order to determine whether the redness depends upon a state of gestion or on other causes. In fact, if the individual has died of an acute disease, we may find more blood than is natural in the brain, although there may have been no congestion. The kind of death must also be taken into consideration: thus the state of the brain and its meninges, gorged with blood from asphyxia, may resemble the injection of active hyperemia.

In examining into the particular seat of congestion, we must keep in mind that the different parts of the encephalon are not supplied with the same quantity of blood-vessels: thus, in the cerebellum there are more than in the brain. The age also causes a difference in the degree of injection, and in the colour of the nervous centres.

External causes.—One undoubtedly exists in the atmosphere, and in the different degrees of temperature. Let us see, first, the action of an elevated temperature, taken from 20 to 50 degrees (Cent. therm.); I shall stop at this last degree, above which life cannot be maintained. From 50 to 40 degrees the individual perishes, or exists but for a time, to die of cerebral congestion, in a manner more or less speedy; from 40 to 35 degrees the same phenomena take place, but are developed with less intensity; sometimes simple congestion is found, sometimes congestion and hæmorrhage: this is remarkable in persons who, like mowers, are exposed all day to the sun. From 35 to 30 degrees, accidents become more rare and less sudden; from 30 to 35, the tendency to congestion disappears.

If a very elevated temperature be an undoubted cause of cerebral congestion, it is not the same with the heat, notwithstanding it may be considerable, of our ordinary summers; but if the temperature be very much reduced, congestions again become more common: frequent examples of this occurred in the retreat from Moscow.

Individuals who pass suddenly from an intense cold to considerable heat, are much exposed to cerebral congestion. There are some singular cases where this has appeared to occur as an epidemic. M. Leuret could only explain an event of this kind, which occurred at the Maison de Charenton in 1823, by referring it to the circumstance of a violent south-west wind, which suddenly blew upon the establishment.

We have nothing very precise on the subject of atmospheric electricity, as a cause of cerebral congestion. However, I have seen all the symptoms of this affection appear in a paralytic individual, who had been subjected to electro-puncture; one of the needles having been applied to the neck, and the other to the lower extremities. Certain circumstances would lead us to the belief that the action of light is not without its influence in producing this affection. It would seem, from some accounts, that one-sixth only of the cases take place during the night.

Alimentary substances.— It is necessary that a predisposition should exist, in order to make the ingestion of our habitual aliment productive of cerebral congestion. But spirituous drinks have undoubtedly a direct action upon the brain; and the odour of alcohol is even said to have been detected in the serum of the ventricles.

Narcotics.—The influence of these, in the production of cerebral congestion, is incontestible, whether they be introduced by the mouth, the rectum, or the skin: but there is here, besides, something specific, for the narcotism is not altogether identical with the congestion resulting from other causes. It would seem, from the experiments of M. Flourens, that opium acts especially on the cerebral hemispheres, belladonna on the tubercula quadrigemina, alcohol on the cerebellum, and nux vomica on the spinal cord.

Internal causes.—If we now inquire how affections of the internal organs can give rise to congestion of the nervous centres, we shall there find causes much more numerous than exist among external agents: and first the brain itself, by its physiological or pathological action, may occasion its own congestion; for example, great mental exertions, strong emotion, or even an hysterical or epileptic paroxysm: indeed, it is from the continuance of congestion after an epileptic attack, that certain other symptoms arise—such as coma, delirium, paralysis; all of which exist only in a transient form, and disappear with the congestion.

Congestion may also result from accidental productions; as the formation of irritants attracting at intervals blood towards the brain, and thus producing the disease of which I speak. Softening and apoplectic affections, more or less chronic, may also give rise to this condition, and we have then two series of symptoms; the one permanent, which depends upon the accidental productions, the other transitory, and which arises from the congestion caused from time to time around the source of irritation.

The diseases of the meninges may excite congestion of the cerebral substance; and, in fact, meningitis is, for the most part, accompanied by injection of the brain itself.

Hitherto I have considered only those causes which have their seat in the nervous centres, or their investing membranes; but there are others.

Digestive system.—Certain states of the stomach may give rise to hyperemia of the brain; such, for example, as a too active digestion in persons who are predisposed. Cerebral congestion also frequently shows itself, particularly in infants, as a consequence of acute gastro-enteritis. We must take care, however, that we do not always attribute to congestion of the brain the delirium, coma, &c. which we see at certain periods of follicular enteritis; for these symptoms, which depend sometimes, it is true, upon hyperemia, may be met with in individuals whose brain is found, on post-mortem examination, to be of remarkable paleness.

Chronic diseases of the digestive canal are not without influence in promoting the disease of which I speak; thus, in certain persons affected with chronic gastritis, each exacerbation is ushered in as if by an attack on the brain, determining congestion to it. We may observe in such an individual, at each exacerbation of his gastritis, a partial paralysis of the arm, which always appears on the same side, and which recedes in proportion as the stomach ceases to suffer.

The diseases of the small intestines are of some account in the production of hyperemia of the brain; the same is the case with affections of the large intestine, where, besides, a special cause exists in prolonged retention of its contents.

Circulating system.—We find numerous causes of cerebral congestion in the organs of circulation. First, if the impetus of the blood exceed certain limits, congestion results. If the palpitations with which a patient is attacked become very strong, there often occur dimness of sight, vertigo, ringing in the ears, numbness, &c. Hypertrophy of the heart ought, therefore, to be ranged among the causes of congestion; but it is not by the mere impulse of the blood by this stroke, as of a piston, that the effect may be produced; if, for example, an obstacle exists to the free return of the blood, the cerebral congestion is produced in a manner quite inverse of the former. M. Tonnele has given some cases of hyperemia of the brain in infants, with obstruction to the circulation in the sinuses of the dura mater; and M. Gintrac, of Bourdeaux, has recorded a similar instance in an adult.

An obstacle to the return of the blood capable of producing congestion may exist exterior to the cranium, as in the jugular veins, or tumors of the neck of different kinds, and goitre among others. Strangulation — a cravat too tightly tied for instance, may produce the same effect. The horizontal position, the head being lower than the trunk, may also occasion it. Let me remark, however, that persons have been known to be immediately seized with cerebral congestion every time that they quitted the horizontal posture. It has also been seen to take place in the fœtus during birth; and hence

results what has been called the apoplexy of new born infants, although it is very seldom that hæmorrhage is found to have occurred in such cases.

Every violent effort impeding the return of blood from the brain may cause this affection, as we witness occasionally in the act of vomiting in individuals who are predisposed; and hence the danger of emetics, which were freely used in cerebral congestion, before Portal had directed attention to the accidents which may occur from this method of treatment. It is not very uncommon to observe fatal congestions of the brain from violent straining at stool. Certain obstacles resulting from vicious formation of the apertures of the heart, on the right side, may produce it, although this be very rare; and simple increased action of the heart, without any defect in its organization, is also sometimes sufficient to excite congestion.

The state of fever without the acceleration or mechanical retardation of the blood of which we have spoken, is productive of hyperemia in certain cases; and it is this congestion which often constitutes the danger in the disease which is called "pernicious intermittent."

We find other causes in the inflammation of other organs. Hyperemia, which is one of the necessary elements of inflammation, may develop itself in the brain in three different manners:—1st, Before the appearance of the inflammation, as, for example, in the premonitory stage of eruptive diseases. 2dly, Simultaneously with the inflammation. 3dly, On the premature disappearance of an inflammation, as of erysipelas of the face.

There are certain morbid conditions to which we can scarcely give another name than that of migratory fluxes, in which in turn, and without ceasing, the different organs are affected with congestion; one day it is the uterus, another the liver, another the lungs, and another the brain. In a word, there are individuals who seem to be under the necessity of having some hyperemia; and it is in such subjects that these congestions frequently end in hæmorrhage.

Qualities of the Blood.—If rich, abundant, fibrinous, high-coloured blood—the plethoric and sanguineous temperament, in fine—predisposes to this disease, the absence of these conditions does not carry with it absolute immunity from its attack.

Respiration.—The disturbances of this function only influence the production of cerebral hyperemia in as far as they impede the circulation; their action is therefore altogether indirect, as in croup, and œdema of the glottis.

Secretions.—While these are normal, they have no marked influence; but it is different with certain morbid secretions, as, for example, the hæmorrhoidal flux, the suppression of which may be immediately followed by cerebral congestion. The suppression of old ulcers, or drains, has a real influence, though one which has been much exaggerated, in the production of the disease of which we speak.

Generative Apparatus.—It cannot be denied that this system has great influence on the brain, and may be productive of congestion; thus at the appearance of the catamenia, and before their establishment, numerous congestions take place, which cease as soon as the menses are established. At the *critical* period we observe those migratory discharges of which I have spoken, and one of which implicates the brain; these conditions, if badly treated, may be productive of formidable organic affections. The absence, or accidental delay, of the catamenia, may cause hyperemia of the brain. In some individuals there is a tendency to congestion at each period; but its locality often depends on the germ of some disease existing in an organ. If the individual is at a later period to have symptoms of disease of the brain, it will be in this organ that the congestion will take place; if it be the lungs which contain the rudiments of disease, it is towards them that the flow of blood is directed, and hæmorrhage may then occur, to which, perhaps, no attention is given; but in this a great error is committed, for under such circumstances there is seldom wanting an organic affection of the lungs.

The abuse of sexual intercourse, as well as too rigid continence, may prove the exciting causes of cerebral congestion.

This disease may also find its cause in certain movements, as whirling. A fatal cerebral congestion has been known to result from walking, an instance of which occurred in a law student here in 1829. (*Vide* Lancette Française, No. 80.)

Age.—All ages are subject to this affection, but it is most frequent after forty.

Symptoms.—These are very variable, and differ very much from each other: 1st, according to the intensity of the congestion; 2dly, according to its duration; 3dly, according to the difference of the parts affected.

Let us first direct our attention to congestion of the hemispheres; of which we shall find several forms, according to the duration and intensity of the disease. In one of the first forms, which is very frequent, the grand cerebral functions—intelligence, motion, and sensation—are not much affected; the sensibility alone is

somewhat disturbed; there is a little headache, dimness of sight, some giddiness, noises in the ear, numbness, sleeplessness; but all this is slight. Occasionally there is a sluggishness of motion, and at other times extraordinary activity, a constant impulse to walk about; sometimes there is a sense of pricking about the limbs or face, and palpitations may occur, whether dependent upon hypertrophy of the heart or on nervous disturbance of that organ. If the congestion be intense, the pulse is strong and vibrating; the pulsations of the temporal artery are sensible to the eye as well as the touch; the capillaries of the face, the cheeks, and even the forehead, as well as those of the conjunctiva, are injected; the veins of the forehead are distended. Sometimes bleeding takes place from the nose.

This first form presents two varieties, according as there is fever or not. If fever be present, it is of the inflammatory type, with determination to the head: its duration under such circumstances, is limited. If there be no fever, the duration is not thus limited, but extends from a few minutes to some hours, or months; and sometimes a constant disposition to cerebral congestion exists for many years. This congestion may shew itself only once, or many times; it is one of those diseases which are very prone to return, recurring sometimes unexpectedly and at irregular intervals. Thus some have such congestions at the return of some particular season; in others we witness those congestions of the brain which are intermittent, presenting the tertian, quotidian, or some other type; and this congestion is described under the name of intermittent apoplexy. After cerebral congestion in this its first form, the health may be entirely re-established, but the other forms may succeed to it, and it also may become complicated with other diseases—as apoplexy, softening, &c.

A second form is much more formidable. At the instant of attack the patient falls down in a state of insensibility, and motionless, just as in apoplexy: this constitutes a *coup de sang*. The cases in which we cannot distinguish this from hæmorrhage are precisely those in which they are of the greatest possible severity—those in which the four extremities are paralysed. In a less considerable hæmorrhage there is generally only hemiplegia; whilst in the *coup de sang* there is for the most part general paralysis. It is only as an exception that we sometimes see hemiplegia: cases of this, however, do occur.

When these symptoms are present, death may take place almost instantly; in some, life is prolonged during several hours without any movement taking place, and without the slightest appearance of sensibility; in others, the symptoms gradually disappear, sensation and movement slowly returning. Nor is this by any means uncommon, but it is more frequent for some affection of certain important functions to remain: the intellect, for example, may continue for some time more or less impaired. There is a sort of stupor or intellectual sluggishness and occasionally delirium, which lasts four or five days, after which the intellect resumes its power. The sensibility is blunted; there are formications; the hearing has lost its acuteness; the sight is less perfect; and there are pains about the head, which are frequently long before they are dissipated. As to motion, the weakness of the limbs is general, or may be more particularly observed in one. Often there is an embarrassment of speech. The frequency of stuttering after the *coup-de-sang* is remarkable. As to the rest, the symptoms disappear more or less rapidly; and if their duration seem likely to be prolonged, there is reason to apprehend greater mischief in the brain than simple congestion.

In the third form, there is loss of intelligence and sensation; but we observe, with regard to motion, a phenomenon which approaches to congestion, accompanied with hæmorrhage—namely, partial paralysis, or in a certain number of cases hemiplegia; however, the hemiplegic symptoms disappear with those of the original attack.

There is one disease in which, although there be no effusion of blood, we often see the same symptoms reproduced. In epilepsy, for instance, we have sometimes a true hemiplegia after a paroxysm, but which disappears one or two days afterwards; and if we have occasion to open the body in a case of this kind, we only find traces of great congestion, but nothing like effusion of the smallest quantity of blood. In some cases intelligence and sensation return, while the hemiplegia remains, although, nevertheless, there has only been simple congestion. M. Leuret has recently published some cases of this kind; I have also seen some instances of it, and there may perhaps be about fifty such on record.

In certain cases, particularly in infants, motion is so effected as to give rise to convulsions, at the same time that intellect and sensation are abolished.

In a fourth form of congestion of the hemispheres, the intellect remains undisturbed, but there are obvious modifications of motion and sensation; similar phenomena are observed in certain hæmorrhages. M. Collier (Bibliothèque Medicale, tome lxi. page 218) quotes the case of a man, 53 years of age, who from his youth had suffered from headache occupy-

ing the anterior part of the head, on the right side. This person was all at once seized with violent giddiness, his sight was disturbed, and he was unable to move. At the same time he had hemiplegia; but his intellect remained entire. These symptoms continued during five minutes, and then became completely dissipated, returning, however, many times each day, for a month, and concluded by being permanently removed. M. Gintrac, of Bourdeaux, relates the case of an infant affected at intervals with complete loss of motion, while hearing, sight, and intellect, remained entire. The movements of the tongue concerned in speaking were as completely abolished as those of the other muscles. What is remarkable in this form is the preservation of intellect.

In a fifth form the principal phenomenon is the loss of intellect. We observe delirium with violent perturbation, screaming, violent muscular agitation of the limbs, and death. It is remarkable to witness the sudden cessation of this great display of strength produced at once by the irrevocable extinction of life, which takes place in the midst of delirium and agitation which has lasted for some days.

Such are the different aspects which congestions of the hemispheres of the brain may assume. How is it that a disease which is identical in its anatomical characters gives rise to symptoms so dissimilar? Can we find any explanation of this difference of form, in the degrees of intensity, and duration of the disease? Or is it necessary to take into consideration the seat of the hyperemia among the causes of these diversities? We can, I think, make out that the symptoms depend for their difference upon the portion of the nervous system which is implicated; but if we wish to go further, and to fix precisely what that point of the brain is, the congestion of which will produce such and such of the forms which have been above described, the attempt fails; it has, however, been made. Thus M. Foville says that delirium without loss of motion and sensation depends upon a change of the cineritious substance—a fact which is far from proved, although it may be possible; and, in truth, it is particularly in irritation of the meninges that delirium occurs. Now inflammation in them reacts upon the convolutions; it is not the meninges which think, but the brain placed beneath these membranes.

Congestions of the Cerebellum.—Different symptoms may manifest themselves, according as the middle, anterior, or posterior part of the brain is attacked, according as the lesion has its seat in one of the large ganglions of Gall, the optic thalami, the corpora striata, &c.; this is intelligible, but it is not demonstrated. There are parts to which especial functions have been attributed; and it has been thought that certain specific symptoms were indicative of their congestion. Take the cerebellum as an example: according as it is held to be the regulator of motion, or the seat of sensibility, or the centre of the generative functions, different inferences are drawn from the symptoms which are observed. Many phenomena have been referred to congestion of the cerebellum: thus the symptoms of intoxication have been attributed to it, because the cerebellum, as I have already said, has been regarded as regulating voluntary motion. But this idea is a bare hypothesis, unsupported by a single anatomical fact.

In certain cases of congestion, the most striking circumstance is the excess of sensibility, which is carried to the highest possible degree; and those who think that the cerebellum is the special seat of sensibility, say that it is this organ which is congested. But neither is this opinion supported by conclusive evidence. There are some facts which seem to favour the idea that the cerebellum rules over the generative functions. I have seen some patients labouring under uterine disease, with dysmenorrhœa, who had acute and continued pains in the occiput at each period. A man came to me one day, who complained that he suffered from very acute pain all over the occiput every time he had sexual connexion. [The gentleman by whom these lectures are reported has a friend who cannot indulge in the least excess in this respect, without having severe pain in the cerebellum and corresponding part of the cranium.] A young man was annoyed by violent priapism; he had severe and constant pain of the occiput for three months; local and general bleeding were employed in vein. Meningitis supervened, and he died; but I regret that no autopsy could be obtained.

Congestion of the Spinal Cord — Let us now see by what symptoms hyperemia of the other parts of the nervous centres becomes known to us: let us take the spinal marrow. This congestion is less frequent than that of the brain or cerebellum, and different parts of the cord may be the seat of the affection; it may attack the anterior column or the posterior, the cervical portion, the dorsal, or the lumbar. The symptoms consist in lesions of motion, sensation, and some acts of organic life; they may not implicate the brain, and they are quite different according as the congestion takes place slowly or rapidly; from this arise two principal forms, viz. acute and chronic hyperemia.

Acute hyperemia of the spinal cord.—This

admits of three subdivisions. In the first form it is motion which is principally affected: thus we observe sudden paralysis of the four extremities, or only of both upper or both lower; in some very rare cases the paralysis is confined to one side and one limb. When cases of this kind occur, we must give close attention to the state of the brain; the mechanical powers of breathing may be impaired, and paralysis of the diaphragm and of the intercostal muscles may cause death by asphyxia; partial or general convulsions may also be present.

In the second form it is on sensation that the morbid effect exerts its special influence; it may be at once abolished either partially or wholly. In some persons, in place of this abolition, there exists only a simple numbness of the limbs, supervening either suddenly or gradually, and deep-seated pain of the limbs, sometimes following exactly the course of the nerves.

In the third form, there is simultaneous lesion both of motion and sensation; and it may happen that these lesions are not of the same kind. Sensation and motion may be increased or abolished, but sometimes there is loss of the power of motion, while sensibility is increased, and *vice versa*. This acute congestion of the spinal marrow may terminate in recovery or death; and this last takes place rapidly when the mechanical powers of respiration are implicated.

Chronic hyperemia of the spinal marrow.—The accidents which occur in this are analogous to those met with in the acute form, but they develop themselves more slowly, and in a different manner. Its duration may be long, and it may be gradually dissipated or be productive of different lesions. When the congestion terminates favourably, we may observe certain critical symptoms, such as hæmorrhage from the nose, intestines, or uterus. A female patient was affected with frequent cerebral congestions, which always relieved themselves by a flow, not of blood, but of watery fluid, which ran from the nose in sufficient quantity to wet a number of handkerchiefs.

Treatment.—In the treatment of every congestion of the nervous centres, three fundamental indications present themselves.

The first is to combat the causes, and these are numerous, as we have already seen. They are found in the atmosphere, in the diet, and in narcotic medicines, in the mode of action of the brain, in the circulating system, in digestion, in respiration, and in the sexual functions.

The second indication consists in emptying mechanically the overloaded vessels by general or local blood-letting. The general bleeding is sometimes preferable when practised on the foot, and congestions have been known to yield to this, after having resisted venesection from the arm; but a grand condition of its success is, that, above all, it be copious; and this is often difficult. Leeches may be applied to the nostrils in persons subject to epistaxis. They may also be placed on the mastoid apophyses, on the neck, along the sagittal suture, on the thighs (particularly when we desire to restore the catamenia), or on the ankles. Generally rapid recovery follows this treatment; nevertheless, in some cases the congestion continues undiminished, notwithstanding the most copious abstractions of blood; and then we must not trust too much to antiphlogistics.

In the third indication, the object is to excite a flow of blood to a part distant from the seat of congestion.

The ancient writers are filled with examples of internal congestions following the disappearance of gout, &c; and I have witnessed some analogous cases. We restore various eruptions to the skin by irritating frictions, with croton oil, tartarised antimony, &c. We may also induce new action on the skin, or bowels, in the former case, by blisters, cauteries, moxa, &c. and in the latter by purgatives, which may sometimes prevent congestions when administered so as to act two or three times a day. If the congestion be already produced, and of an acute kind, very active purgatives require to be employed. In some cases an attempt has been made to produce an abundant salivation. It is a precarious method, because the increase of the salivary secretion necessarily attracts the blood towards the head, and may thus render the congestion more intense.

MIDDLESEX HOSPITAL.

Extracts from a Clinical Lecture by Dr. Watson.

Cerebral Hæmorrhage, combined with, yet not depending upon, Hypertrophy of the left ventricle of the Heart.

Mary Nagle, aged 60, was brought to the hospital on the 26th of October, insensible, with palsy of the left side of the body. Pulse 70, labouring. Pupils contracted.

She had suddenly fallen down in a fit of apoplexy on the 24th. Between the attack and her admission consciousness had in some degree returned, and she then complained of pain in the right side of the head. Afterwards she relapsed into a state

of deep coma. She had been bled in the right jugular vein.

She gradually sank; and died early in the morning of the 29th.

The body was examined the same day.

The bony skull-cap adhered firmly to the dura mater. The external veins of the cerebrum were full of dark blood. The surface of the arachnoid was quite dry.

The right lateral ventricle contained a large, dark, soft coagulum of blood, and was further distended by a considerable quantity of bloody serum. The foramen of Monro was widely open; and the left lateral ventricle was also full of serum, tinged with the colouring matter of the blood. On further examination it appeared that the coagulum occupied a large portion of the right thalamus opticus, of which the texture, to a certain depth, was crushed into a pulp. The cerebral matter immediately adjacent to the broken part was dotted with blood. The vessel from which the blood had escaped was not detected. The basilar arteries were much altered by disease; presenting many irregular opaque spots, and a manifest inequality of calibre. The arachnoid at the base of the brain had lost its natural transparency.

The heart appeared to be of the normal size; but the thickness of the walls of the left ventricle was very greatly increased, while its cavity was unusually small. The right ventricle also was small. The mitral valve was thick, stiff, and puckered; so that nothing larger than one's thumb could pass easily from the auricle to the ventricle. The other valves were quite healthy. Just behind and beyond the aortic valves, a few small atheromatous specks were visible, of a whiter colour than the surrounding membrane. Elsewhere the aorta was free from disease.

In a clinical lecture, among other remarks upon this case, Dr. Watson called the attention of the pupils to the coincidence it presented of cerebral hæmorrhage with hypertrophy of the left ventricle of the heart: a coincidence so frequent as to have led to the notion, often, if not always erroneous, that the one was the physical cause of the other. In this instance it was plain that no such relation of cause and effect could have obtained. The cavity of the left ventricle was so much diminished, that the momentum of the column of blood driven forwards by its contraction must have been less, instead of being greater, than what is natural. The true explanation of the hæmorrhage in the brain is to be found in the diseased condition of the cerebral arteries. Usually, indeed, with such a morbid state of those vessels we find associated the same kind of change (a deposit of albuminous matter, diminished elasticity, and dilatation) in the commencement of the aorta. And this disease of the main artery will virtually obstruct the free passage of the blood out of the heart, and thus account for the increased bulk and thickness of the ventricle. But in the present case the aorta was very nearly healthy: and the hypertrophy had resulted from the alteration which the *mitral valve* had undergone. One consequence of this alteration must have been that the ventricle did not receive its due proportion of blood from the corresponding auricle: and it is presumable that the ventricle, thus imperfectly supplied, was teased (if the expression may be allowed) into preternatural effort or frequency of contraction: and this increase in its natural action would explain, upon well-known principles, its augmented muscular bulk. Dr. Watson had more than once seen this combination of hypertrophy with diminished capacity of the left ventricle, when the passage of the blood from the auricle had been mechanically impeded by disease at the mitral orifice. It is not, however, a very common accompaniment of disease in the mitral valve: usually there is disease of the aortic valves also, or of the aorta, and *dilatation* as well as hypertrophy of the ventricle.

The lecturer observed that the facts of this case were directly opposed to the opinion generally prevalent respecting the kind of connexion that subsists between apoplexy and hypertrophy of the heart; while they tended to confirm the views he had long entertained, and frequently expressed, on the same subject*.

In the course of the same lecture, after noticing three cases of poisoning which had been brought to the hospital during the preceding fortnight—the poison swallowed in one case having been aquafortis, in another arsenic, and in the third oxalic acid—Dr. Watson made some observations, of which the following is the substance,

Upon the use and the abuse of the Stomach-Pump.

It is too much the fashion to employ the stomach-pump in every case of poisoning; with the view either of removing the poisonous substance, or, if that has already been accomplished by the efforts of nature, of introducing antidotes and diluents. I wish to caution you against this indiscriminate use of an instrument which, under proper regulation, is really invaluable. Doubtless many lives have been saved by it which without it would inevitably have been lost; but it is no less true that the same instrument is very often resorted to when

* See Med. Gaz. vol. xvi. p. 21.

it need not be used at all; and even when its employment can scarcely be otherwise than injurious. What, in fact, are the uses of the stomach-pump? They are simply two: that of conveying fluids into the stomach is one; that of extracting fluids from the stomach is another.

Now, when a patient is both able and willing to swallow, *that* is at once the quickest and the easiest method of effecting the first of these purposes. On the other hand, should the patient be insensible; or too weak to perform the necessary acts of deglutition; or should he obstinately refuse to swallow, as not unfrequently happens when suicide has been attempted; in all these cases, the stomach syringe offers an admirable resource, and overcomes a most perplexing obstacle to our curative endeavours.

Again, if a person is vomiting, or can be brought to vomit, and the vomiting is or can be kept up by the frequent administration of warm drinks, this is the easiest, the safest, and the most effectual way of ridding the stomach of its contents. But, if the patient be in a state of insensibility; or if the stomach itself have been rendered by the poison insusceptible of the impression of emetics, which commonly have a speedy operation; or if, from the nature of the poison, such emetics be even likely to fail, and danger is impending from further delay; then, again, in this simple instrument we often find the sure and ready means of relieving the stomach of its deadly burden.

There are some cases, then, and those of poisoning by opium are pre-eminently of the number, in which the aid of the stomach pump is almost indispensable: and there are others in which its employment is unnecessary, and therefore, in my opinion, wrong and blameable. But this mechanical way of getting rid of the noxious matter which the stomach may contain has something very satisfactory and attractive about it, to the operator at least, if not to his patient: and I make no doubt that it will continue to be insisted upon by the one, and submitted to by the other, in numerous instances in which the operation is not actually requisite; yet in which it does good and palpable service, and inflicts no injury.

What I wish, however, chiefly to get you to attend to and consider, is, that there are cases in which the use of this instrument may be hazardous, or positively hurtful. The introduction of the tube always implies some degree of violence to the parts along which it passes—to the fauces, œsophagus, and stomach. Slight hæmorrhage from these parts is no unusual evidence of this. In the hands of an inexpert or clumsy person it may become, even under ordinary circumstances, a most formidable weapon. I am not sure that I have not myself seen inflammation of the larynx produced by its mismanagement; and mischief of a still more surely fatal character has been witnessed by others. Some time ago a patient was brought here who had taken poison (sulphuric acid, I think it was), and for whose relief the stomach-pump had already been resorted to. Death presently ensued; and the body was opened in the dead-house below. I was not at the hospital on that day; but the examination was conducted in the presence of many persons, pupils and others, and of Mr. Alexander Shaw among the rest. Upon his information and authority I relate these circumstances. Besides other appearances, which I need not specify, a large quantity of *chalk mixture* was discovered in the *wind-pipe*: and the air-passages being thereupon carefully traced, many of the larger bronchi, and considerable portions even of the vesicular texture of the lungs, were found to be choaked and plugged up with the same substance. This had been thrown in by means of the pump; unquestionably with the best intention, but it had passed in a most unfortunate direction: it had missed the road to the stomach, where it might perhaps have been of some service; and it had entered the lungs, where it could scarcely fail to prove destructive, even if the patient's life had not been already endangered by the poison. Even when the tube has been carefully and skilfully introduced, it is by no means an impossible thing for the mucous membrane of the stomach to be sucked into the orifices at its extremity, and for serious mischief to be *so* produced; and where corrosive substances have been swallowed, and the gullet and stomach have already been inflamed or abraded by the poison, the friction of the pipe will be likely to augment the existing injury, and may even cause irreparable damage. If, after taking caustic poison, the patient cannot swallow, still less can he with impunity receive the tube of the instrument. I am not stating merely possible or imaginary dangers: I remember seeing the stomach of a girl who died in St. Bartholomew's Hospital many years ago, and in whose case the stomach-pump had been used. There were three long strips of the mucous membrane of the stomach hanging loose in its cavity: they had evidently been torn up by the tube. You may see an accurate representation of that stomach in the first part of Dr. Roupell's admirable set of plates illustrative of the effects of poisons. I do not imagine that, in this particular instance, the condition of the patient was rendered materially worse by this mishap: she had no chance of recovery from the effects

of the arsenic she had swallowed, *a considerable portion of which still remained in the stomach.* But I mention these untoward occurrences to shew you that the stomach-pump is not always a harmless instrument; that care, and some, though surely not much skill, are required for its introduction; that it can never be considered a matter of indifference whether it be employed or not; that it is chiefly, if not solely, admissible where narcotic poisons have been taken; that in the case of corrosive poisons especially, it is to be used, if at all, with great caution; and that it never should be used at all if the patient be able and willing to swallow, and if full vomiting can be excited without it.

I have still to warn you of another danger to be apprehended from the prevalent application of the stomach-pump in all cases of poisoning indiscriminately,—a danger quite distinct from any that have yet been pointed out: the danger, namely, under certain circumstances, of the *delay* which it implies. There are poisons of which the deadly operation is capable of being averted by antidotes, and yet is so rapid that remedies are of little avail unless they are administered very soon after the poison has been swallowed. Oxalic acid is a poison of this kind; and of its fatal effects you have just seen an example. Dr. Christison has already admonished the profession that the time expended in giving emetics, or in using the stomach-pump, is time lost, in cases of poisoning by this substance, *when antidotes are at hand;* and you will observe that the best antidotes, chalk and magnesia, are much more frequently at hand, and in nine cases out of ten are much more readily procurable, than is the stomach pump.

I fear that the error against which I am endeavouring to guard you has been fostered by the high degree of favour that the stomach-pump has obtained with the public, who readily apprehend its advantages, but are not so quick in perceiving its possible demerits. Medical men are sometimes, I suspect, induced to employ the instrument merely in compliance with this popular sentiment, and lest it should be imputed to them, as a fault, that in circumstances of urgent danger they had neglected an important remedy. A gentleman well known to you all, who was formerly house-surgeon here, Mr. Charles Beevor, has told me that he was once rated by a coroner's jury for having, in the sound and proper exercise of his discretion, abstained from introducing the stomach-pump in a case of poisoning which terminated fatally. The poison was oxalic acid. Similar absurdities are not uncommon at inquests. It requires, perhaps, some share of moral courage to disregard prejudices of this kind, especially when they are likely to be publicly expressed, and may, however wrongfully, prove injurious to the reputation of the practitioner. The requisite degree of this mental firmness may best be ensured by a thorough comprehension of the circumstances which, in certain cases, justify, and even demand, the adoption of the expedient in question; and in certain other cases as plainly forbid it. I am anxious not only that you should satisfy your own minds upon these important points, and act according to your conviction; but also that you should do what you can, each in his own circle of influence, to diffuse sounder notions than have hitherto prevailed respecting them, throughout the community.

CONDUCT OF THE "COUNCIL OF THREE" AT SOMERSET-HOUSE TOWARDS THE MEDICAL PROFESSION.

To the Editor of the Medical Gazette.

Sir,

I should not have intruded so soon again on your notice but for the perusal of the leading article in the Lancet of November 21st, in which the Editor (perhaps displeased at the castigation you have so deservedly bestowed on the Poor-Law Commissioners) attempts to exonerate them from censure, and to fix the onus exclusively on the Boards of Guardians.

Now there is a manifest injustice in any such endeavour to shift the responsibility of these enormities from the *superior* to the *inferior* functionaries, or to attach the entire blame to a numerous and *unpaid* body of country gentlemen, while the high salaried "council of three," who have the power of absolute dictation in the administration of the poor-law, are excused and justified.

If the view which your contemporary takes of the matter were correct, and if the Poor-Law Commissioners did really intend to afford adequate and efficient medical attendance to the pauper population, why did they not issue their directions expressly to that effect?

The "permissive authority" delegated to guardians, to appoint as many medical men as they think proper (with which the commissioners attempted to satisfy the Kent deputation, and upon which your contemporary lays so much stress) is practically useless as a preventive to the present wide spreading evil.

As long as there are inducements held out to the local boards to limit the medical appointments to a few individuals, and as long as the commissioners *enforce* the absurd and unjust system of pecuniary com-

petition, so long will a "permissive authority" of this kind be a mockery of redress.

The plea of non-interference with the medical arrangements of the boards, with which the commissioners have sometimes met the remonstrances of the profession, is equally destitute of foundation. Facts which will probably ere long be before the public, *entirely disprove it.* It is true the commissioners have not interfered to remedy the alleged grievances, but they interfered in numerous instances to uphold and encourage the boards of guardians in the course complained of, and to check and oppose them when inclined to act in a reasonable and considerate manner.

Again, where the gentlemen at Somerset House have not themselves interposed, their representatives (the assistant commissioners) have frequently done so; upsetting the previous medical arrangements of the guardians, threatening and calumniating the resident practitioners, and, if still unsuccessful, putting their threats into execution by introducing some of their unemployed protegés.

The truth of this may be verified on a large scale by a reference to the various counties in which opposite plans are pursued. Comparatively few complaints are made from *Hampshire* and *Northamptonshire*, the assistant commissioners in these counties having apparently acted in a considerate and liberal manner; while the public prints of *Suffolk*, *Buckinghamshire*, and *Kent*, (as well as private communications) where a different order of gentlemen hold the sway, teem with cases of grievance.

If further evidence were wanting, the last Report presented to the Secretary of State, which I suppose to be the production of the Commissioners of both grades, will prove conclusive. A document more calculated to embue the public mind with feelings of jealousy and suspicion towards the whole body of country practitioners, could hardly be penned. It is a wanton and unprovoked *general* attack on men whom they have previously been maltreating individually. The impression made by this report is evinced strongly by a letter in the *Times* of November 28, signed "Rusticus," to which, if not anticipated by an abler hand, I shall endeavour to reply to-morrow.—I am, sir,

Your obedient servant,

RURICOLA.

Dec. 33 5.

SPURIOUS EDITIONS OF MEDICAL WORKS.

To the Editor of the Medical Gazette.

SIR,

IN your journal, No. 414, a correspondent has exposed the attempt at imposition upon the public by a bookseller in the Old Bailey; and if Henderson merits (and I *know* he does) the censure of your correspondent, I think you, sir, and your numerous readers, will agree with me in opinion, that the proceedings of a bookseller in the Borough strictly merit the same treatment.

Perceiving an advertisement, a few days since, of a new London Dispensatory, by Drs. Cox and Gregory, to which was appended a translation of M. Magendie's Formulary, for twelve shillings, I was induced to purchase the same. On examining it. however, I found the Dispensatory was an *old* work, published *eleven years since!* by *a son* of the publisher's, and to which a Dr. Gregory has furnished a translation of Magendie's Formulary. This *New* Dispensatory, therefore, is a cheat, and ought to be exposed.

But, sir, this is not all. When in the country in the summer, I saw Mr. Lawrence's Lectures on Surgery, Medical, and Operative, advertised on the cover of your excellent journal, and I ordered it accordingly, when, to my astonishment, I found only *twenty* lectures out of the course, which extends to (I believe) eighty-eight. Is this conduct honourable? Surely the industrious student ought not to be silent when such aggressions are being made upon his purse. The publisher's name and address is E. Cox, St. Thomas's Street, Southwark.

I am confident your sense of justice will induce you to give insertion to this letter, if only as a caution to the numerous students now in London.

I am, sir, with much respect,
Your obedient servant,

WM. C. NIAARP.

MORISON'S PILLS.

ANOTHER EXAMPLE OF THEIR DELETERIOUS NATURE.

To the Editor of the Medical Gazette.

SIR,

ONE would suppose that the mind of the public had, by this time, been tolerably well enlightened regarding the nature and fatal effects of this pernicious nostrum. Nothing can exceed the self-sufficiency and utter ignorance of the itinerant quacks of the establishment who scour the country, imposing upon the weak and credulous. It were, indeed (as suggested in the Gazette of last week), to be desired that every medical man would endeavour to rid the world of such detestable knavery, by giving publicity to cases of violent injury, or death, resulting from this medicine,

falling within his immediate observation. I lately visited a gentleman at Oxford, who was mourning the loss of a friend snatched prematurely from his family. Relating the particulars, he told me that the deceased had been for some time unwell, but not so greatly as to cause serious apprehensions. In a weakened state of body he had resorted to Morison's pills, and the result was, that after two or three full doses, hypercatharsis was induced, and the patient was carried off. No doubt existed in the mind of my informant as to the real cause of death; but as the unfortunate gentleman had been ailing for a considerable period previously, no public notice was taken of the catastrophe.

I am, sir,
Your obedient servant,
R. H. Allnatt, M.D.

Wallingford, Dec. 10, 1836.

HENDERSON'S EDITION OF CUVIER.

To the Editor of the Medical Gazette.

Sir,

I perused with much pleasure the spirited letter relating to the publication of the above work, signed "P." published in the number of the Medical Gazette for November 7th, page 190. I suppose you have his address; if so, I will thank you to send him the inclosed letter. I trust the generality of the subscribers will unite with him in the attempt to punish the agent of so vile an imposition.—I remain, sir,

Your obedient servant,
R.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By Jon. Pereira, Esq., F.L.S.

Lecture XII.

The last order of mammals in the Cuvierian arrangement is that denominated

CETACEA,

from which we obtain Spermaceti. In exterior form these aquatic animals are like fishes; they have no posterior extremities, the tail terminates in a horizontal fin (in this respect, however, differing from the tail of fishes, which is always vertical), and the anterior extremities form likewise fins. You will not, therefore, be surprised to find that all the early naturalists classed them among fishes. Our countryman, Ray, called them "*pisces pulmone respirantes;*" and Linnæus even, in the earlier edition of his *Systema Naturæ*, committed the same error. But a little examination will soon satisfy you they deserve a much higher position in the animal scale. They respire by means of lungs, and hence are compelled to rise frequently to the surface of the water (in which they are assisted by the horizontal direction of their tails) to take in air. They have warm blood, the sexes associate in the manner of terrestrial animals, they bring forth living young, and they have two mammæ (either abdominal or pectoral) to suckle their offspring; so that having the same general structure as mammals, and performing the same general functions, they must of necessity be classed with them.

To the characters I have already mentioned as distinguishing this order, I have only to add, that the neck is very short, the pelvis rudimentary (consisting merely of two bones unconnected with the rest of the skeleton), the lateral expansions of the tail are cartilaginous, and not osseous as in fishes; and in some of the cetacea there are teeth, while in others these organs are replaced by horny plates (*whalebone.*) Although there is a considerable variation in their development, yet the enormous size of many of these animals is one of the most amazing facts in their history.

Zoologists make two families of cetacea: *one* is called the *Sirenia*, by Illiger, Goldfuss, and others, but by Cuvier the *Cetacea herbivora*. In this are comprehended all those animals endowed with the faculty of leaving their watery habitation to crawl and pasture on the shore, and which have two pectoral mammæ. Here are contained those beings which have given rise to the fabulous accounts of the mermaids, the sea-nymphs, &c. The *second* is the *Cete*, or *Cetacea ordinaria*, of Cuvier, and which are piscivorous. The animals of this order have a smooth, shining, naked skin, covering a thick fatty layer. The mammæ are two in number; but instead of being pectoral, as in the herbivorous cetacea, they are placed near the genital organs. They swallow an immense quantity of water along with their prey, and get rid of it through the spout hole at the top of the head; it is expelled with great violence by the action of powerful muscles. From this circumstance these animals have been termed *hydraula*, *souffieurs*, or the *blowers*. The following table will explain the subdivisions of cetacea:—

				Genera.
Cetacea	with two pectoral mammæ (*Sirenia*, seu *Cetacea herbivora*) ..			Manatus. Halicore. Rytina.
	with two abdominal mammæ (*Cete*, seu *Cetacea ordinaria*) ..	Head in ordinary proportion to the body		Delphinus. Monodon.
		Head inordinately developed ..	Teeth in lower jaw	Physeter.
			no teeth	Balæna.

PHYSETER MACROCEPHALUS.

History. — The genus physeter (from φυσαω, to blow) contains those whales usually denominated *cachelots*, a term derived from the word *cachau*, and signifying in the Biscayan language, a *tooth*. The number and characters of the species are badly determined; but the *long-headed cachelot*, called by Shaw and Bonnaterre the *P. macrocephalus* (from μακρος, long, and κεφαλη, head) is the most common. It is supposed by Cuvier to be the *orca* of the Latins, and the *physeter* of Pliny. The first correct figure and description of the animal was published by Clusius in 1605.

Description.—The length of this animal is from 50 to 60 feet; its head constitutes about one-third of the length of the whole body. The jaws are small; the lower one is shorter, smaller, and lower, than the upper, and is furnished with from twenty to twenty-three teeth on either side. Shaw states that an accurate inspection of the upper jaw proves there are corresponding teeth in that also; but they are very small, and situated so deeply within the sockets, as to be totally invisible on a general view.

The presence of teeth in the lower jaw readily distinguishes the cachelots from animals belonging to the genus Balæna, which in the adult state are destitute of teeth, though in the fœtus they are observed, but soon disappear. In the upper jaw of the Balæna we meet with numerous broad, horny, flexible plates, disposed in regular rows on each side, and which are commonly known by the name of whalebone. The fringed edges of these serve as a kind of strainer, and to retain the prey, the water being allowed to escape. The great Greenland, or whalebone whale, is the *B. mysticetus*, and is from 50 to 60 feet long.

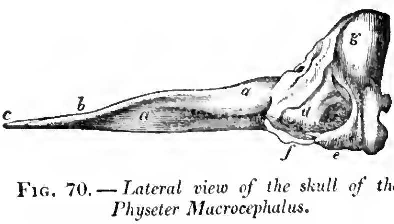

FIG. 70. — *Lateral view of the skull of the Physeter Macrocephalus.*

The snout of the cachelot, notwithstanding its prodigious length, is formed, as in the dolphin, only by the maxillæ (*a a*, fig. 70,) on the sides, by the intermaxillæ (*b b*) towards the median line, and by the vomer (*c*) on this line. The intermaxillæ project to form the anterior part of the snout. Posteriorly the right one ascends higher than the left. The spout hole is single (in most cetacea it is double), and directed towards the left side, so that whenever the animal spouts water, it is to that side only.

Seat of spermaceti.—Spermaceti is found in several parts of the body of the animal, mixed with the common fat. The head, however, is the grand reservoir for it. Here it is found (mixed with oil) in a large excavation of the upper jaw, anterior to, and quite distinct from, the true cranium which contains the brain. (See fig. 70, where *d* represents the parietal bone, *e* the zigomatic apophysis, *f* the jugal bone, and *g* the occipital bone.) Mr. Hunter states that the spermaceti and oil are contained in cells, or cellular membrane, in the same manner as the fat in other animals; but besides the common cells there are larger ones, or ligamentous partitions going across, the better to support the vast load of oil, of which the bulk of the head is principally made up.

There are two places in the head where this oil lies; these are situated along its upper and lower part: between them pass the nostrils, and a vast number of tendons going to the nose and different parts of the head. The purest spermaceti is contained in the smallest and least ligamentous cells; it lies above the nostril, all along the upper part of the head, immediately under the skin and common adipose membrane. These cells resemble those which contain the common fat in the other parts of the body nearest the skin. That which lies above the roof of the mouth, or between it and the nostril, is more intermixed with a ligamentous cellular membrane, and lies in chambers whose partitions are perpendicular. These chambers are smaller the nearer to the nose, becoming larger and larger towards the back part of the head, where the spermaceti is more pure.

Such is Mr. Hunter's account of the locality of spermaceti. He adds that he discovered about the nose, or anterior part of the nostril, a great many vessels, having the appearance of a plexus of veins, some

as large as a finger. On examining them, they were found loaded with spermaceti and oil; and some had corresponding arteries. They were most probably lymphatics; therefore he supposes their contents had been absorbed from the cells of the head.

At one time spermaceti was supposed to be the seminal fluid of the whale, and from this received its name. It was then thought to be the brain of the animal. We now know its nature, though we are not acquainted with its precise use in the animal economy. The enormous quantity of fatty matter with which the cetacea are supplied, probably serves to preserve the heat and to diminish the specific gravity of these stupendous hot-blooded animals.

Has spermaceti been found in any other organized being than the cachelots? Chevreul states he obtained a substance very similar to, though not identical with, cetine (the pure part of spermaceti), in *Delphinus globiceps*; Vauquelin found a substance analogous to cetine in the *Agaricus campestris* (fig. 71); Gmelin says spermaceti is also procured from *Delphinus edentulus*. A crystalline matter (cetine?) is deposited from the common whale and other fish oils.

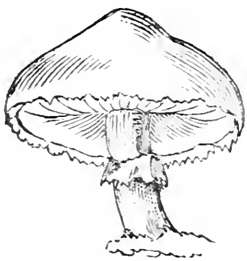

Fig. 71.—*Agaricus Campestris.*

Preparation of spermaceti.—When the fatty substance found in the head (hence called *head matter*) is exposed to the air, it concretes into opaque masses. It is dug out, and the oil allowed to drip from it. When brought to England, it has a yellow semifluid or unctuous appearance; and in order to remove as much of the oil as possible, it is submitted to compression in hair bags, placed in an hydraulic press. It is then melted in water, and the impurities skimmed off: subsequently it is remelted in a weak solution of potash. By fusion and proper cooling, it is obtained in the form met with in the shops.

Properties.—The spermaceti of commerce usually contains a small portion of yellow oil: if this be separated, the pure product is called *cetine.* The oil is best removed by boiling the spermaceti in alcohol.

Cetine is a white laminated substance, without taste, and almost odourless. It is insoluble in water, and slightly soluble only in alcohol when at a boiling temperature. By saponification with alkalies, we obtain margaric and oleic acids, a yellow extractiform substance, and *æthal.*

100 parts of *cetine* yield (with probably 2·5 of water)	Margaric and oleic acids ..	60·96
	Æthal	40·64
	Extractiform matter	0·9
		102·50

To obtain these products, we proceed as follows:—Digest one part of cetine with one part of hydrate of potash and two parts of water: this yields us spermaceti soap. When this is decomposed by an acid, the extractiform matter is left in solution, while the fatty acids and the æthal are separated. As there is an increase of 2·5 per cent., we must refer this either to the air or water (most probably the latter), the elements of which have entered into new combinations.

Æthal is a crystalline, solid, non-saponifiable fat; it is odourless, tasteless, combustible like wax, and may be distilled. When fused, it solidifies at about 118°. It is insoluble in water, is readily soluble in hot alcohol and in æther. It is composed of carbon, hydrogen, and oxygen: the two first constituents were supposed by Chevreul to be in the same relative proportion as in æther and alcohol; and hence the word æthal was taken from the first syllables of these words.

	Carbon.	Hydrogen.	Oxygen.	Nitrogen.
Spermaceti (Berard)	79·5	11·6	8·9	0
Ditto (Saussure)	75·474	12·795	11·377	0·354
Cetine	81·660	12·862	4·578	0
Æthal	79·766	12·945	6·289	0

Physiological effects and uses.—Like other fatty bodies, the local action of spermaceti is emollient—that is, it relaxes the tissues to which it may be applied. When used to sheath surfaces it is called demulcent. The usual mode of exhibiting it internally is to suspend it in water by means of the yelk of an egg; but being a very troublesome preparation, on account of the fatty matter mixing less readily with water than many other oily substances, it is now rarely employed. In irritation of the alimentary canal, as dysentery and diarrhœa, and of the pulmonary membrane, as catarrh, it is occasionally beneficial.

Its most common medicinal use is in the formation of cerates and ointments. In the London Pharmacopœia we have a cerate and ointment of cetaceum, each of which is ordered to be composed of spermaceti, white wax, and olive oil, but in different proportions. As, however, most of the white wax met with in commerce is mixed largely with spermaceti to render it white, these preparations are never made according to the intentions of the College. Practically this is of no consequence.

AMBERGREASE.

This substance is a product of the spermaceti whale, but as it is not an article of medicine in this country, my notice of it must be very brief.

The best account of the method of procuring it is in the 57th volume of the Philosophical Transactions, for the year 1783. It is found floating on the surface of the sea. The best is brought from Madagascar, Surinam, and Java.

Ambergrease seems to be the fæcal matter of the cachelot, probably hardened and otherwise altered by disease. Some have considered it analogous to biliary calculi: its chemical properties favour this supposition.

It is a solid, opaque, greyish, striated substance, having a pleasant musk-like odour, and which is supposed to be derived from a species of cuttle-fish (*sepia moschata*) on which the animal feeds. In favour of this opinion must be mentioned the fact, that the horny beaks of a sepia are found imbedded in it. Its specific gravity is from 0·908 to 0·92.

It consists principally of a non-saponifiable fat, analogous to cholesterine, but mixed with excrementitious matter. This fatty substance has been termed *ambreine*. It is soluble in alcohol, and by the action of nitric acid furnishes a peculiar acid (*ambreic acid*).

Analysis of Ambergrease, by John.

Ambreine	85
Sweet balsamic alcoholic extract, with benzoic acid	2·5
Aqueous extract, benzoic acid, and chloride sodium	1·5
Loss	11
	100·0

Its action on the system is considered to be analogous to that of musk.

Class 2.—Aves, or Birds.

Having now finished our examination of all the orders of the class *Mammalia* which yield us any pharmacological agent, we advance to the next class—that of *Aves*, or Birds. Here the only substance which I have to notice is the egg of the common fowl; but before examining it I must premise that this class has received its name *Aves* from the Hebrew, and literally signifies *fliers*. Blainville calls them *Penniferæ*, from the circumstance of their skin being furnished with feathers. I regret that I cannot permit myself to detain you with any detail of the distribution, the structure, or the mode of development of feathers; the subject is an exceedingly interesting one, but I do not feel warranted in consuming so much time as would be requisite for its proper investigation. All that I think it right to say respecting birds is, that they are oviparous bipeds, and, therefore, have no mammæ; their blood is warm and red, with elliptical particles; their heart is furnished with four cavities. Being destined to live and be sustained in the air, birds have their anterior extremities formed into wings; their respiration is by lungs, the air penetrating even into the bones. In the skeleton of the animal we observe a peculiarity about the pectoral region: the two clavicles unite at an angle to form the *furcula* or merry-thought, and they are furnished with two coracoid bones. They have two larynges, the superior one simple; the inferior one, placed at the bifurcation of the trachea, is provided with muscles, and is the seat of the voice.

Orders of aves.—In the Cuvierian arrangement six orders are admitted, as follows:

1. *Accipitres* (from *accipiter*, a hawk), called also Raptatores, the birds of prey—such as the vulture, eagle, &c. They have short feet; their toes are armed with claws, and the bill curved or hooked.

2. *Passeres* (from *passer*, a sparrow), or the passerine birds, includes all the small singing birds; they have four toes, three in front and one behind, the outer toes being wholly or in part united.

3. *Scansores* (from *scando*, to climb) or the climbers,—sometimes called Picæ or the

Pies. It includes the Parrots. They have four toes, two in front and two behind.

4. *Gallinæ* (from *gallina*, a hen) called also Rasores, Gallinaceous birds, or commonly poultry, includes the domestic fowl. They have their toes in front, united at their base by a short membrane.

5. *Grallæ* (from *grallæ*, stilts), or the Waders, as the Ibis, have elevated naked tarsi, the two outer ones being united.

6. *Palmipedes* (from *palma*, the palm of the hand, and *pes*, a foot), the web-footed animals, or the Natatores, as the Duck. Their toes are united by broad membranes.

PHASIANUS GALLUS.

History.—Some doubt exists as to the origin of our common domestic cock and hen. Sonneret affirms that all the varieties originate from the jungle fowl (*Gallus sonnerati*, fig. 72); while Temminck refers them

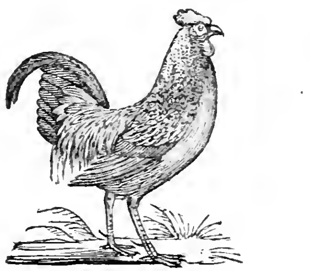

FIG. 72.—*Gallus Sonnerati.*

to the Javan fowl (*Gallus lanckiva*). If external appearance is to be a guide, the latter assertion is the more probable.

No mention is made of this animal in the Old Testament, but in the New, the male and female are each mentioned. However, the reference to the cock is involved in some doubt; since it has been supposed that the *crowing of the cock*, alluded to by Christ when speaking to Peter, had reference to the third watch of the night, called ἀλεκτοροφωνια, or *cock-crowing* watch. Aristotle calls the male animal ἀλεκτρυὼν, the female ἀλεκτορις: both terms are derived from ἀλεκτρος, without sleep.

Description.—This animal is so well known as to require very little description. The zoological characters of the genus are the following: — Bill somewhat thick, strong, and curved at the apex; the nostrils are placed at the base of the bill—they are half closed by an arched scale. The head is surmounted with a fleshy vertical crest, and the lower beak is furnished on each side with fleshy wattles. Tail compressed, and composed of fourteen feathers. The tarsi of the male are furnished with a long and bent spur. The varieties are very numerous.

Production of eggs.—The *yelk* of the egg is formed in the ovarium, from whence it passes into the oviduct, where it receives the *white*, or glaire; proceeding onwards, it afterwards obtains its *shell*.

1. *Ovarium.* — First let us commence with the *ovarium*, called also the *racemus vitellorum*, or the egg organ. This consists of a cluster of ova, in a hen beginning to lay, about 500; the stalk by which each ovum is attached to the ovarium is called the *petiolus.* The size of the ova is exceedingly various: when quite ripe, they are as large as the yelk of an egg; the smaller ones are white, the larger ones yellow. Each ovum, when ripe, is composed of a calyx—the yelk bag—and the yelk.

(*a.*) The *calyx* constitutes the outer coat or covering of the ovum, and consists of two layers—an outer one, derived from the peritoneum, and an inner one, which is somewhat thicker. Between these two coats the vessels ramify. The *petiolus* is merely a prolongation of the calyx: it is studded with a number of small ova resembling vesicles. On that part of the calyx of a ripe ovum which is opposite the petiolus, is a whitish curved stripe, called the *stigma*, indicating the spot where the calyx bursts, to allow the escape of the yelk.

(*b.*) *Yelk bag*, or *membrana propria vitelli.*—This is within the calyx, and closely invests the yelk. It is a flocculent, delicate, fine coat.

(*c.*) *Yelk*, or *vitellus, with the cicatricula*, or *tread.*—In the early state of the ovum, the yelk is constituted of a pellucid fluid lymph, and is hardly distinguishable from the *vesicula cicatriculæ.* It then becomes whitish, and subsequently yellow, globules of oil making their appearance. In a ripe ovum, it is viscid, tenacious, and of an orange-yellow colour; and lies in the calyx, with its long axis towards the petiolus. It is composed of three layers, (fig. 73,) the middle one having the deepest

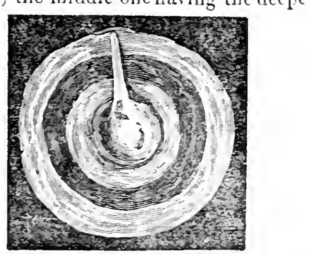

FIG. 73.

colour: the innermost inclosing a white fluid, called the *albumen centrale*, or the *substantia alba vitelli*; from which, according to Purkinje, passes a *little canal* to that part

of the surface of the yelk called the *cicatricula*.

The internal surface of the yelk-bag is lined with a very thin stratum of globules, in form and figure like those of the blood, but arranged organically. The *cicatricula*, or *tread* (as it is improperly called), is formed by an accumulation of these globules forming a mammiform heap, the convexity of which is towards the centre of the yelk, and is usually situated nearer the petiolus than the stigma. In the top of this is the so-called pellucid *pore*, which is occupied by a small vesicle discovered by Purkinje, and called by him the *vesicula germinativa*, or *vesicula cicatriculæ*. It is found in all

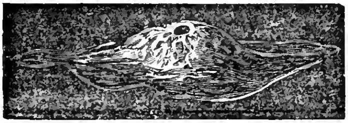

Fig. 74.—*Cumulus Cicatriculæ*, with the *Pore* in the centre: from Purkinje.

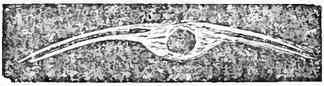

Fig. 75.—Section of the *Cicatricula*, shewing the *Vesicula* in sitû.

the ovarian ova, and seems to be a natural organ, since it is found in the ova of fowls which have never had access to the male, When the yelk falls into the infundibulum this vesicle disappears; in all probability being broken by the contractions of the oviduct. It is adherent to the yelk-bag.

2. *Oviduct*.—The oviduct has some resemblance to a convoluted intestine. It is situated on the left side of the animal. Its superior expanded free extremity is called the *infundibulum*, the edges of which are fimbriated. Inferiorly, the oviduct opens into the cloaca. It is attached to the spine by the *mesometrium*, usually regarded as analogous to the mesentery, but which Purkinje calls "a muscular membrane." From its upper end (called mesometrium superius) a process termed the *ligamentum infundibuli* passes to the last rib but one on the left side. The coats of the upper part of the oviduct are exceedingly thin; those of the lower part are considerably thicker. As the structure and functions of the different parts of the oviduct are different, some anatomists have divided it into three portions—namely, the *genital tube* (tractus oviductus, or oviduct, properly so called,) the *uterus*, or middle portion, and the *vagina*, or lower part, which opens into the cloaca. Of the propriety of some division of the oviduct, no person who examines it can doubt; but it must be admitted the above terms are objectionable, since the parts to which they refer do not perform the functions which their names would lead us to suppose. Thus the part called the *uterus* does not contain the ovum while the chick is developed. Let us examine the changes which the ovum undergoes in its passage through this tube.

The *infundibulum*, or expanded portion of the tube, receives the ovum as it escapes from the calyx of the ovarium. The upper part of the oviduct is lined by a fine villous membrane, covered with follicles secreting the albumen, or glaire and thrown into a number of longitudinal folds. The first layer of albumen which the ovum receives, forms the *membrana chalazifera* of Dutrochet; at either end of which is a soft, pellucid, albuminous nodule, which may be regarded as the *rudimentum chalazarum*. During the descent of the ovum in the oviduct, it receives fresh deposits of albumen; and as it undergoes spiral rotations in its passage, the above-mentioned processes become curved spirally, and in the perfect egg constitute the *chalazæ*, *grandines*, *appendices albuminis*, or the *poles* or *treddles*. From one chalaza to the other is observed in many eggs one or more white striæ, formed by a thickening of the membrana chalazifera. Vicq d'Azyr called this appearance the *zona albicans*.

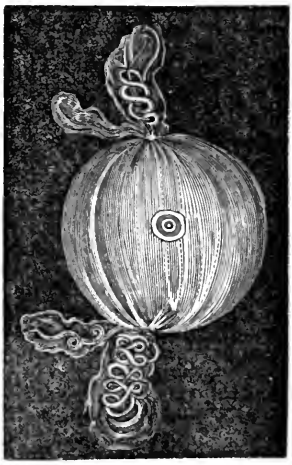

Fig. 76, showing the yelk, with the *spiral chalazæ* at the extremities, the circular *cicatricula* in the middle, and the *zona albicans* extending from one chalaza to the other.

The *albumen*, *glaire*, or *white* of the egg, is not uniform in its consistence. The thickest is that which is first deposited around the yelk. Proceeding from without inwards, the three layers of albumen are termed *Albumen primum*, *A. secundum*,

and *A. tertium.* Just before the egg arrives at that part of the oviduct called the uterus, it receives its outer coat, the *pellicula ovi.*

In the so-called uterine portion of the oviduct is formed the *calcareous shell.* Some are expelled without it; these are termed *oon eggs.* The chalk is first deposited in small polygonal pieces, having a crystalline appearance (fig. 77); but when the de-

FIG. 77.

posit has attained a certain thickness, all traces of crystallization are lost, though small pores are left, so as to allow a passage for the air. This is proved by the fact, that if an egg be varnished, so as to prevent the influence of the atmosphere, incubation is stopped.

Having now traced the egg from its first appearance to its most perfect state, we may proceed to describe its general properties.

General description of the egg.—The elliptical or oval form is well known. The specific gravity is from 1·080 to 1·090. By keeping the water evaporates, and in its place air is substituted; so that eggs become lighter. Dr. Prout found that in two years an egg lost $544\frac{3}{10}$ grains, or about 0·75 grain in twenty four hours. The relative weights of the different parts of the egg were, according to the same authority—

Shell and membrane	106·9
Albumen	604·2
Yelk	288·9
	1000·0

By boiling in water, an egg loses from 20 to 30 grains (supposing the original weight of the egg to be 1000 grains.)

1. The *putamen ovi* or *egg-shell* consists principally of carbonate of lime. Here are the analyses of it by Vauquelin and Prout:—

	Vauquelin.	Prout.
Carbonate lime	89·6	97
Phosphate lime and magnesia	5·7	1
Animal matter (with traces of sulphur and iron)	4·7	2
	100·0	100

This calcareous matter renders the shell absorbent and antacid, and hence its employment to neutralize the acid of wines.

2. The *pellicula ovi*, or the membrane lining the shell, possesses the characters of an albuminous substance; it dissolves in alkalies, and from this solution is precipitated by acids. It weighed about 2·35 grains (the whole egg being 1000 grains.) At the larger end of the egg it forms the *folliculus aëris.* According to Bischoff, the air in this cavity is similar to atmospheric air, with the exception that it contains more oxygen—namely, 23·475 per cent.

3. The *albumen ovi*, called commonly the *glaire*, or white of the egg, is on the whole, perhaps, the most interesting part to us in a medicinal point of view. It consists of two or three laminæ, which are deposited on the yelk while in the oviduct. These laminæ, however, are not homogeneous; for there are at least two parts detectable in them, namely, a solid, probably organized, albumen, having the appearance of a very fine delicate membrane, forming a series of cells, in which are contained the liquid albumen. The solid albumen is brought into view in two ways—either by shaking the glaire with water, when you observe a white, membranous, and insoluble tissue; or by examining the glaire by means of a microscope, two unequally refracting substances are evident. On moving the mirror of the microscope from right to left, the play of light (according to Raspail, and my own observations bear out his assertions) renders visible an indistinct interlacing net-work, an appearance which could not take place if the albumen did not consist of at least two substances Again, when the albuminous layer begins to dry, the transparent

texture is seen gradually to exhibit large indentations, and, as it were, a kind of large globules more or less agglutinated together, as well as anastomosing folds, resembling vessels. Now this could not take place were the albumen an homogeneous substance.

The glaire, or white of egg, has been analysed by Dr. Bostock. It consists of a coagulable substance (*albumen*), an uncoagulable matter (called by Bostock *mucus*, by Marcet *muco-extractive*, by Gmelin *salivary matter*), salts, and water.

	Gmelin.	Bostock.
Albumen	12·0	15·5
Mucus	2·7	4·5
Salts	0·3	0·0
Water	85·0	80·0
	100·0	100·0

Albumen is distinguished from all other animal substances by the circumstances attending its coagulation. It is not spontaneously coagulable, and hence is readily distinguished from the liquid fibrine of the blood; but it coagulates by heat, galvanism, acids, alcohol, many metallic salts, &c., and hence we readily know it from non-coagulable animal substances, as mucus, gelatine, &c. Caseum and serai are distinguished from the albumen of the egg by not being coagulable by heat, though they are by some other agents. The theory or cause of its coagulation is, in many cases, still a mystery, no explanation yet offered being satisfactory. It is probable, however, that the phenomena are different under different circumstances of coagulation.

It appears that albumen is a substance which can combine with either acid or basic bodies: with the first it forms, for the most part, insoluble, with the second soluble compounds. Thus most of the acids, added to an albuminous liquid, cause a precipitate, which, according to Thenard, possesses acid properties. I may show you, as examples, sulphuric, nitric, tannic, and gallic acids, as having this effect. Now I think we can best understand these changes by regarding the precipitates as insoluble salts, the base of which is albumen, and therefore we might term them *sulphate*, *nitrate*, *tannate*, *gallate*, &c. of *albumen*. On the other hand, albumen forms soluble compounds with the alkalies, which Berzelius has denominated *albuminates*, as if the albumen acted the part of an acid: in this white of egg, then, we have the *albuminates of potash and soda*. But certain metallic salts cause precipitates with albumen: as examples, I shall select corrosive sublimate, the persulphate of copper, the perchloride of tin, and the nitrate of silver. What is the nature of the change here? Thenard tells us that the precipitates consist of albumen, the metallic oxide, and some of the acid. Orfila says that the precipitate caused by corrosive sublimate is composed of calomel and albumen; though from a remark made by Berzelius, it may be suspected to be corrosive sublimate and albumen. I cannot help suspecting that these precipitates are also to be regarded in the light of double salts. We know that corrosive sublimate, sulphate of copper, chloride of tin, and the nitrate of silver, are all capable of forming double salts, in which they act as the acid or electro-negative ingredient. If this be correct, the precipitate caused by corrosive sublimate is to be regarded as a *chloro-hydrargyrate of albumen* (query? of chloride of albumen). Alcohol coagulates albumen possibly by abstracting water. How heat acts I will not pretend to offer an opinion, never having met with any hypothesis, in my opinion, at all probable. The liquid albumen of the white of egg is distinguished from that of the blood by its being coagulated by æther, which the latter is not.

The following are the relative proportions of the saline principles of the albumen of eggs, according to Prout, as determined by three experiments; the weight of each egg being assumed to be 1000 grains:—

Yellow oil (with crystallizable fat)	28·75
Albumen (containing phosphorus in some unknown state of combination)	17·47
Water	53·8
	100·02

The *mucus* of white of egg is not affected by heat, a solution of corrosive sublimate, nor by infusion of galls; but it is copiously precipitated by the subacetate of lead.

4. We proceed now to describe the *yelk* of the egg. By carefully removing a portion of the shell, you bring into view the *cicatricula*, a circular appearance on the

yelk. On whichever side you open the egg, you always observe this spot upwards; this is effected by the chalazæ, which are not attached in the axis, but a little on one side of the yelk, so that the latter revolving in the white by means of the chalazæ, the smaller, and, therefore, lighter portion always remains uppermost. Observe at each extremity of the yelk the twisted flocculent *chalazæ*. The yelk is inclosed in a sac called the *yelk bag*.

The yelk is regarded as a kind of emulsion, consisting of oil suspended in water by means of albumen. Its composition is as follows:—

	Sulphuric Acid.	Phosphoric Acid.	Chlorine.	Potash, Soda, and Carbonate of do.	Lime, Magnesia, and Carbonate of do.
Experiment 1 ..	0·29	0·45	0·94	2·92	0·30
Experiment 2 ..	0·15	0·16	0·93	2·93	0·25
Experiment 3 ..	0·18	0·48	0·87	2·72	0·32
Average	0·206	0·463	0·923	2·84	0·29

Lecanu obtained a small portion of cholesterine.

The *oleum ovi* is thus obtained: The yelk of an egg, which has been boiled hard, is to be dried, and then digested in alcohol, which dissolves the oil; and by distilling off the alcoholic solution, we obtain the oil in a separate state. The oil may also be obtained simply by pressure from the yelks.

The saline principles found in the yelk are, according to Prout, as follows:

	Sulphuric Acid.	Phosphoric Acid.	Chlorine.	Potash, Soda, and Carb. of ditto.	Lime, Magnesia, and Carb. of ditto.
First Experiment	0·21	3·56	0·39	0·50	0·68
Second Experiment	0·06	3·50	0·28	0·27	0·61
Third Experiment	0·19	4·00	0·44	0·51	0·67
Average ..	0·153	3·68	0·37	0·426	0·65

I may remark here that it is probable the sulphuric acid obtained from albumen is a product of combustion, and exists in it as sulphur; the phosphoric acid in the yelk as phosphorus; the chlorine as chloride of sodium. There are some curious and highly interesting circumstances connected with the saline principles of eggs. Prout has established the fact that the earthy matter found in the skeleton of the chick when it quits the shell, does not pre-exist in the recent egg; so that the only possible sources whence it can be derived are the shell, or transmutation from other principles. Now the former is highly improbable for several reasons. It is tolerably clear that Dr. Prout believes in the capability of the vital energies to effect this transmutation, though he does not assert it.

Effects and uses of the albumen and yelk of eggs.—Both substances are nutritive; their local action is emollient and demulcent. The white, or albumen, is a valuable agent in the treatment of certain cases of poisoning—namely, poisoning by corrosive sublimate, the preparations of copper, and the perchloride of tin. In these instances it acts as a chemical agent. It is also useful in other corrosive or acrid poisons, as a demulcent or sheathing agent. The yelk has been employed for preparing emulsions (especially that with spermaceti), and its oil has been employed as an application to cracked nipples.

The white, or glaire, is used for clarifying liquids and wines. In coagulating, it entangles in its meshes the impurities, and either rises with them to the surface, or precipitates. When the liquid to be clarified does not spontaneously coagulate the albumen, it is necessary to employ heat.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

By Dr. Latham.

ON SYMPTOMS.

Auscultatory Symptoms—Bronchial Respiration and Bronchophony—Dry Sounds; where and how they are produced; incident to several Diseases; peculiar to none—Their analogy to certain Sounds of the Heart in the mode of their production—Estimate of their value as Auscultatory Symptoms— Their value relative, not absolute; and little or great, according to circumstances—as seen in Phthisis, in Pneumonia, in Pleurisy.

Upon the subject of Auscultation, hitherto we have only considered certain sounds occurring during the act of respiration, and have endeavoured to estimate the amount of the information they furnish concerning diseases of the lungs, both by themselves and by their interference with the respiratory murmur. And we have found that, arising, as they do, from certain pathological conditions of the mucous membrane which lines the air-passages, they become *direct* symptoms of all those pulmonary diseases into which such conditions enter as ingredients.

The sounds which I have called Rhonchus and Sibilus, and large and small Crepitation, in the sense the terms bear at this hospital, and which others have called by other names bearing an equivalent sense, these sounds cannot carry us further in the diagnosis of pulmonary diseases than I have pointed out. Other sounds are required to detect pulmonary diseases, consisting of other pathological conditions, or occupying other structures.

Of these other sounds, some still respect the respiration, some the voice, and some the act of coughing. There are what are call the Bronchial Respiration and the Bronchial Voice, or Bronchophony; and as Bronchial Respiration and Bronchophony will always be found to denote the same thing, I will consider them together.

When there is Bronchial Respiration you hear the breathing, and when there is Bronchophony you hear the voice, as you never hear them when all is healthy. In health, the respiration reaches the ear through the chest, in a clear, smooth, uniform murmur. In health, the voice does not reach the ear at all through the chest, except when it is applied just opposite the first divisions of the tracheæ—viz. on either side the second and the third dorsal vertebræ: but in certain conditions of disease you perceive, at particular situations of the chest, while the patient breathes, audible *gusts* of air puffed in and puffed out of the lungs, instead of the smooth respiratory murmur; and at the same situations, while the patient speaks, a sort of humming or muttering, but no articulate word. Such is Bronchial Respiration, and such Bronchophony.

Now these sounds, accompanying the respiration and accompanying the voice, are called Bronchial, because they are formed in those first divisions of the air-tubes which are popularly called Bronchi. But the Bronchi themselves are not in fault; they need not themselves have undergone any disease or a change of structure whatever, in order to the production of these sounds.

Bronchial Respiration, or Bronchophony, arise when the lungs have undergone such changes of condition as are calculated to render them better conductors of sound than they are in their natural and healthy state.

Now there are so many diseases and so many morbid processes involved in, or contingent upon, those diseases, which have the common effect of rendering the lungs more solid, and thus augmenting their capacity of conducting sound, that Bronchial Respiration and Bronchophony cannot be diagnostic of any one in particular. The lungs are consolidated in phthisis by tubercles; in pneumonia, by effused lymph; in pulmonary apoplexy, by effused blood; in hydrothorax and empyema, by compression, from without, of accumulated serum and of pus;—and in each of these affections, Bronchial Respiration and Bronchophony are apt to occur. But they are not properly diagnostic either of phthisis or pneumonia, of pulmonary apoplexy or pleurisy.

In going round the hospital, I have often taken occasion to point out to you cases of phthisis, in which the sounds of the heart were audible over the entire chest, or a considerable part of it. With the sounds themselves, their kind, their rhythms, their succession, no fault was to be found; only they were heard beyond their natural limit, and were perhaps a little louder th n natural. The impulse of the heart, in the meantime, has not been remarkably strong; perhaps it has been remarkably feeble, and the general state of the circulation has not indicated disease.

In such cases, where, during life, the sounds of the heart have been heard thus constantly and habitually beyond the precordial region, I have found, upon examination after death, that the organ it-

self has not exceeded, and often that it has fallen short of, the natural and average dimension.

When the heart is perfectly healthy, it must depend upon conditions exterior to itself if the sounds which accompany its contraction be heard not only in the precordial region, but both there and beyond it. In the cases I have mentioned, it depended upon the condition of the lungs; which being rendered more solid by the tuberculous matter within them, and becoming better conductors of sound, conveyed the sounds of the heart extensively through the chest.

In particular instances of phthisis, where the patient has been long under my observation, I have sometimes remarked that the audible limit of the heart's sounds has varied from time to time, according to circumstances, which seemed to me not difficult to explain. During the first stages of the disease, and in proportion as the lungs have been more and more beset with *crude* tubercles, they have reached further and further beyond the præcordial region; during the later stages, and in proportion as the tubercles have been more and more changed into vomicæ, they have receded more and more within their proper bounds.

And, not in Phthisis only, but in other and curable diseases within the chest, are examples found of the sounds, which accompany the heart's contractions, being conveyed beyond the præcordial region, while the lungs are rendered more solid by the various products of morbid action; and again receding within that region when reparation has taken place, and the lungs have again become pervious and free. Pneumonia, pulmonary hæmorrhage, and pleurisy, will often, during their progress, conduct the sounds of the heart half over the chest; and the cure of pneumonia, pulmonary hæmorrhage, and pleurisy, will often bring them back again within their just limits.

In like manner, and for the same reasons, and under the same conditions of disease, do the *bronchi* acquire a resonance, or a voice, which in no wise belongs to them, when the surrounding structures are perfectly healthy.

Such I believe to be the true account of Bronchial Respiration and Bronchophony. They are dry sounds, according to the explanation already given, being not produced by the mingling of air with fluid.

It now remains to determine the value that belongs to Bronchial Respiration and Bronchophony, as Auscultatory Signs. If they be taken *absolutely* and *alone*, their value cannot be rated very high; for, inasmuch as they do not attach themselves to any single morbid process, but result from conditions that are common to many, they can never be *exclusively* trusted for the diagnosis of disease; yet they may be trusted very often for lending important aid towards it. In truth, their value consists rather in what they contribute as auxiliaries to other signs than as standing alone.

As auxiliaries their value varies very much, according to the circumstances of the particular case; and as other auscultatory signs present are more or less precise, and stand less or more in need of that confirmation which these are capable of contributing.

Bronchial Respiration and Bronchophony are worth very little in Phthisis, when Gurgling Respiration, and Gurgling Cough, and Pectoriloquy, have already put their authentic stamp upon the disease.

They are worth very little in Pneumonia, when the Respiratory Murmur has been gradually overcome by small Crepitation, and small Crepitation been succeeded by dulness, and no sound is now elicited by percussion, or yielded to the listening of the ear.

They are worth very little in Pleurisy, when already, over one half the chest, the ear detects no Respiratory Murmur, and percussion can produce no Resonance; when the heart is pushed from its proper seat, and the patient is fixed on this side or that, by a dread of suffocation if he move to the other.

Yet it may happen in these several diseases, that the Bronchial Respiration, the Bronchial Voice, may throw just that light which is needed upon a number of doubtful symptoms, and give just that guidance which is required to a right diagnosis.

Phthisis may exist; but you cannot certainly pronounce that it exists, though the flesh may waste and the strength decline, and the pulse be habitually more frequent than natural, and the breathing be habitually a little hurried, and some cough be habitually present without expectoration; from all these circumstances you cannot *certainly* pronounce the disease to be phthisis; you still need the help of some auscultatory sign to decide your diagnosis. But a little help is *now* enough. If the Bronchial Respiration or the Bronchial voice be *now* added, and be always present, and always found in the same place, you may securely trust either one or the other as the sure index of phthisis.

Yet bronchial respiration and bronchophony are not *absolutely* diagnostic of tubercles or vomicæ, or of any morbid process essentially phthisical. But it is enough that in this case they are *circumstantially* diagnostic; for as such they are infallible.

Pneumonia may exist; but if you can have no sure evidence of its existence,

though fever be present, and Small Crepitation be more or less diffused through the lung. But if to this Crepitation Bronchial Respiration or Bronchophony be added, these, which are but indirect symptoms of condensation of the lung, are, *under the circumstances*, as certain tokens of such condensation having already begun, as if the chest at some part already yielded no sound to percussion; and none either healthy or morbid to the application of the ear. Small Crepitation is, indeed, the auscultatory sign of inflammation in the smaller bronchial ramifications; yet as long as this is the *only* auscultatory sign, there is a hope that the inflammation may pass away without involving structures beyond them. But Bronchial Respiration and Bronchophony *are* enough to shew that it has involved other structures, and that air is admitted less freely into the pulmonary vesicles.

In cases of Pneumonia, Bronchial Respiration and Bronchophony will sometimes precede, by no inconsiderable period, those auscultatory signs which more directly declare an impervious state of some portion of the lungs. And in cases of Pneumonia, Bronchial Respiration and Bronchophony will often exist at one part of the lungs, while Crepitation still exists at another: whereas, dulness to percussion and to auscultation do not arise until the Crepitation has ceased, and then are found exactly in those situations where the Crepitation was before. Bronchial Respiration and Bronchophony seem to denote the growing incapacity of the general pulmonary vesicles to admit as much air as they ought: dulness to percussion and auscultation shew the exact portions of the lungs that are absolutely impervious.

Pleurisy may exist. Fever, dyspnœa, and pain in the side, are enough to create a strong suspicion of it; a *suspicion*, however, and no more. But only let the least auscultatory sign be added, and the suspicion becomes a certainty. Bronchial Respiratory, or Bronchophony, is as much much as you want. One or the other, found in any part of the affected side, and known not to have been there before, will at once fix the character of the disease. They show *absolutely* that the lung is beginning to suffer compression; and they show *circumstantially*, i. e. by their union with fever, dyspnœa, and pain in the side, that the compression in the present case is from fluid effused into the cavity of the pleura, which is the first effect of its inflammation.

But wait a little in this case: and, if the inflammation be not arrested, and if the effusion within the pleura increase, the Bronchophony will be attended by a peculiar echo. And this echo (if echo it be) is the very pathognomonic sign of Hydrothorax. It has been well likened to the bleating of a goat, and therefore called Œgophony. But is a sound that admits of varieties, and as been denoted with equal propriety by sveral similitudes.

Wait yet a little longer: and if the fluid still increase, the Bronchial Respiration, the Bronchophony, and the echo, and every the least perceptible sound, will cease.

Finally, concerning Bronchial Respiration and Bronchophony, if it be thought that they are things far too trivial to bear out such vast conclusions as, in one case, that the lungs are beset with tuberculous matter, and the disease is Consumption; in another, that inflammation, either in itself or in its products, has travelled beyond the brochial ramifications, and the disease is Pneumonia; and in another, that inflammation has fallen upon the pleura, and Hydrothorax is already begun, I repeat, that this mere Resonance of the Breathing and the Voice within the larger bronchi, is diagnostic of these diseases, not in itself, but *circumstantially*, and in the relation it bears to other symptoms.

And thus we see, in the daily practice of medicine, that things in themselves mean and of no account, do often, by their place and by their relations, gain a just preponderance over things more prominent and striking, and have the largest share in guiding our decision upon the most important questions.

Cavernous Respiration and Pectoriloquy—Dry Sounds—Where and how produced—Cavernous Respiration has many modifications—Whence these are derived—They cannot and need not be characterized by names—Conditions most favourable to Pectoriloquy—Gurgling Respiration and Gurgling Cough—Moist Sounds—How and where produced. These four Auscultatory Signs, Caveruous Respiration and Pectriloquy, Gurgling Respiration and Gurgling Cough, are chiefly concerned in the Diagnosis of Phthisis—Estimate of their value in each stage and form of this disease.

But there are other Auscultatory signs which respect the respiration and the voice—those, namely, which are called Cavernous Respiration, and Pectoriloquy. I will consider them together, as I did Bronchial Respiration and Bronchophony, because they too will be found to signify the same things.

We call it Cavernous Respiration when, during the act of breathing, a hollow sound reaches the ear through the walls of the chest from some circumscribed space within. And we call it Pectoriloquy,

when, during the act of speaking, the articulate words that are uttered reach the ear through the walls of the chest from a circumscribed space within.

Cavernous Respiration and Pectoriloquy both result from a cavity formed in the lungs and communicating with the bronchi. They are, in the sense already explained, Dry Sounds—*i.e.* not requiring the presence of fluid for their production.

In Cavernous Respiration the hollow sound probably does not begin to be formed until the air enters the cavity, and results altogether from reverberation against its sides; whereas in Pectoriloquy the articulate sound is first formed in the larynx, and then conducted down the trachæa, and entering the cavity, is merely augmented by reverberation against its sides.

I am convinced that the whole subject of Auscultation would have been better understood if a little less artifice had been used in the methods of teaching it—a little less industry to find a name for every sound that is heard. This very sound of "Cavernous Respiration" has been puzzled and perplexed to the student by the fancy of giving an express name to each of its modifications.

There may be, perhaps, now in the hospital, a dozen patients who have Cavernous Respiration; and in each one of them the sound, besides being cavernous, has some distinct peculiarity: it is large or it is small; it is a click, or a hum, or a squeak. It is like blowing into a bottle with a narrow neck, or into one with no neck at all; it is like the flapping of a valve; it is metallic; it is as if air was puffed *into* your ear, or as if air was drawn *from* it.

It would be easy enough to agree upon a dozen terms to designate the dozen different sorts of Cavernous Breathing in the patients now in the hospital; but then the next dozen patients would require as many new terms for as many sorts of Cavernous Breathing, which would still be different.

The varieties of Cavernous Breathing are doubtless owing to the different size and form and situation of cavities, and the different conditions of the surrounding lung.

A cavity may be very large or very small. Several bronchi may open into it, or only one. It may be a simple cavity, or it may have many chambers. Its sides may be condensed and equal, or rough and ragged. The lung around it may be solid and indurated, or pervious and vesicular. It may be near the ribs, or far from them; adherent to, or separate from, the pleura.

It is quite obvious that these different circumstances are calculated to modify the sound, which will, nevertheless, be always such as indicates a cavity.

Would you know what Pectoriloquy is, put the tube upon the larynx or trachea of a healthy man, and, when he speaks, his voice will seem to come through his throat, and pass directly up the instrument into your ear. Just in this manner does the voice reach the ear through the chest, when the conditions within are favourable to Pectoriloquy.

The conditions *most* favourable to Pectoriloquy are that the cavity should have dense walls, that it should be near the surface of the lung, and that, by mutual adhesion of the two pleura, the walls of the chest should themselves contribute to form it, and that the cavity itself should be empty. Thus a cavity that produces Cavernous Breathing may still not produce Pectoriloquy. It must not be too small, or it will not allow sufficient reverberation to the voice; it must not be too large, or the voice will be lost in an indefinite hum. Thus there may be a cavity without Pectoriloquy, but a cavity can scarcely exist without Cavernous Respiration.

There is yet another auscultatory sign, which belongs to the respiration. It results from the mingling of air with fluid in the act of breathing; but it is heard in a circumscribed space, and evidently proceeds from a much larger quantity of fluid than is capable of being accumulated in the mere bronchi within such a space.

The French call it Gargouillement; we call it Gurgling. It is essential to this sound that there be a cavity, and that the cavity contain fluid.

The Gurgling sound of the Respiration is exactly like that which a boy makes when he blows up soap suds with a tobacco-pipe.

Allied with the Gurgling Respiration, and requiring the same conditions to produce it, is the Gurgling Cough. I wish, however, I had another term for the sound which attends the act of coughing: for it is certainly different from this gargouillement of breathing. If you place your ear upon the chest, immediately over a considerable cavity containing pus, or any fluid that admits air to pass through it, and tell the patient to breathe rather deeply and rapidly, you will hear the sound of a hundred great bubbles agitating the fluid and bursting in continual succession. But if you place your ear upon the chest, and tell him to cough, the sound is as if the whole contents of the cavity struck against your ear at once. The one sound is a *gurgling*, the other a *plash*. I wish Plash was not such an awkward word; for it expresses the very thing.

In the effort of coughing, more air penetrates the cavity. It goes in and out of it with a rush. Moreover, it dwells longer in it, and while it is there, the whole chest suffers a succussion. Thus, by the act of coughing, not only are the air and the fluid mingled and agitated together within the cavity, but the cavity itself is shaken, like a bottle, against the ear.

This audible Plash of fluid is certainly produced during coughing, as well by the general succussion of the chest which then takes place, as by the forced impulse and agitation of air within the cavity itself. Indeed, mere succussion alone will produce it; and succussion occasioned by other means than by coughing. Very often, when the cavity has been close to the walls of the chest, and the patient has been much emaciated, after I have heard its contents Bubbling as he breathed, and Plashing as he coughed, I have desired him to hold his breath for a few seconds, and abstain from coughing if he could; and still I have heard distinctly a smaller sound of the same kind, a Plashing synchronous with the pulse. This sound is doubtless owing to the motion derived to the same cavity from the impulse of the heart.

And now for the practical application of the several Auscultatory signs; Cavernous Respiration and Pectoriloquy, Gurgling Respiration, and Gurgling Cough. To illustrate their diagnostic use I will take only one disease, but one which includes many and various morbid changes in the structure of the lungs, and see how far these signs, either by themselves or as auxiliaries to others, enable our knowledge to keep pace with such changes, as they arise. That disease shall be Pulmonary Consumption.

Let us consider Pulmonary Consumption in the stage of its first development, its most uncertain, but its most fearfully interesting stage. An individual is suspected to be Phthisical: he has some fever, some acceleration of pulse, some emaciation, and some cough; all inconsiderable in degree, yet all abiding; but no expectoration.

In a patient thus supected to be phthisical, auscultation may discover no more than this, that beneath the clavicle and about the scapula the Respiratory Murmur is less clear on one side than on the other, and that, where the Murmur is defective, there, too, the chest is less resonant to percussion.

Now if, after repeated examinations, auscultation comes always to this result, no doubt can remain that Tubercles are already formed in the upper lobe of one lung.

But here is no unnatural sound, only the natural sound is in part defective; and this must arise from some impediment to the passage of air through that portion of the lungs. Now impediment may arise from the deposition of lymph, or any of the common products of inflammation, as well as from Tuberculous matter. But inflammation is very unapt to take place, and its products to be effused into the apex of an upper lobe, while every other part of the lungs remains unaffected by it. It may ultimately reach this situation, but seldom, very seldom, begins in it. On the other hand, it belongs to Phthisical disease to deposit Tubercles in the upper lobes first, and thence gradually to scatter them over the rest of the lungs.

Thus by help of Auscultation, but still rather by what we do *not* hear, than by what we *do*, we arrive as surely at the persuasion that there are Tubercles in a certain case, as if there were sounds properly denoting their existence, which there certainly are not.

Always bear in mind that there are no Auscultatory signs which expressly bespeak tubercles. You are left to get at the knowledge of their existence by that sort of evidence which has been called circumstantial; Auscultation, however, having an important share in the result. As thus, Auscultation finds the Respiratory Murmur defective at a certain part of the lungs; and hence we infer its obstruction by the deposition of some kind of matter or other. But the part is that which nature chooses, above all others, for the deposition of Tuberculous matter; and hence we further infer that the matter is Tuberculous in this particular instance. But, moreover, the constitutional symptoms are such as are wont to accompany Phthisical disease; and hence we finally infer almost a certainty that Tubercles are deposited at the upper part of one lung. We conclude that the thing must be, because it *can* be nothing else. Circumstantial evidence, it is acknowledged, may be as infallible as the evidence which bears direct attestation to the simple fact.

I have been speaking of the Auscultatory Signs that we possess of Consumptive disease, when it has proceeded no further than the deposition of Tubercles (crude Tubercles) at the apex of one lung.

In proportion as Tubercles are more largely deposited in one lung, or extend to both, the Auscultatory Signs are the same in kind, but more definite; and the portions of lung that are healthy are more strikingly contrasted with those that are diseased. The healthy part, being called upon to compensate by a more energetic Respiration for the absence of Respiration in the diseased, gives out a louder and more Puerile Murmur, while the diseased gives out no Murmur, or almost none at all.

Recollect, I introduced the subject of Auscultation for the sake of illustrating to you the best means we have of knowing organic disease by direct symptoms. But, if there be any signs, not Auscultatory, which either give direct intimations of disease in the same organ, or tend to give more force and precision to the Auscultatory, it is fit that I should introduce them as I go along.

At no period of Consumptive disease is hæmoptysis more apt to take place than at this which we are now considering, when the lungs are beset by crude Tubercles. And the hæmoptysis illustrates the Auscultatory Signs, and the Auscultatory Signs illustrate the hæmoptysis.

The cases are numerous in the course of a twelvemonth which I see in this hospital and elsewhere, of hæmoptysis occurring in every quantity, from a tea-spoonful to a pint, in individuals whose general health has been previously declining, but who have had no particular complaint except (what they have called) a little hacking cough.

The great majority of such cases, as far as the mere hæmoptysis is concerned, do well. In a few days the hæmoptysis entirely ceases, and very often the patients tell you that they are better since they spat blood than they were before. It is my habit, however, to keep such patients still in the hospital for a week or a fortnight, to satisfy myself respecting the actual condition of their lungs, as far as I can learn it by Auscultation.

And Auscultation gives the same results which have been described. Respiration is unequally performed in different portions of ths lungs. There is less Respiratory Murmur perceptible about the scapula, or beneath the clavicle, on one or both sides, and less Resonance upon Percussion, than elsewhere.

I would invite your attention to all such cases as these, whenever you meet with them in the hospital. I recommend you particularly to exercise yourselves, whether by Auscultation or otherwise, in detecting the signs of Tubercles deposited in the lungs at the earliest possible period: because it is *then* especially that a sound knowledge of the real state of things may enable you to do infinite good, by seasonable, and (I will add) practicable advice to postpone the progress of disease, and protract many a valuable life.

I do not wish you to fasten on small points, and swell them into importance, and by refining and sophisticating to make something out of nothing at all, and frighten families, and deceive yourselves into a belief that you have cured Consumption.

The cases I am pointing out are those in which there are well-defined constitutional symptoms—fever, wasting of the flesh, acceleration of pulse. These denote something going on wrong somewhere. The cough fixes suspicion upon the chest; and the chest being examined gives such results as I have mentioned.

Let us now consider Pulmonary Consumption in other stages. In all stages, subsequent to the Tubercular, the Auscultatory sounds are paramount and unerring, and you may implicitly trust to them for your entire knowledge of each and every other morbid change and process incident to the structure of the lungs from Pulmonary Consumption.

The earliest and the least, but still a very authentic sign of Vomica, derived from Auscultation, is a mere Click, or slight ringing sound, heard in Breathing, at some point beneath the clavicle or about the scapula, in a patient in whom all the surrounding parts have been for some time dull. This Click, to remove all doubt of its being owing to the accidental lodgement of a piece of tough phlegm in one of the Bronchi, must always be found at the same point at several examinations of the chest. This is one modification of Cavernous Respiration. It results from a cavity or vomica in its first formation, when the Tuberculous matter is softening, and when it is just beginning to admit air.

Those who have been accustomed to attend me for any length of time in my visits round the hospital, must know how often I have pointed out this particular sign, this little Click in the Breathing, and desired them to listen to it day after day, until they gradually found it change into a Cavernous Respiration of a more certain character.

Where there is a Cavity, in the progress of its enlargement and of the changes it undergoes, its Auscultatory Signs are to be sought in Breathing and Coughing and Talking. Breathing will give them in one case, Coughing in a second, Talking in a third. Or often in the same case, whether the patient breathe, or cough, or talk, the evidence of a Cavity within the lungs is equally authentic.

Thus the Respiration, the Cough, and the Voice, may all give equal assurance that vomicæ exist; one confirming the other, and all agreeing in the same result.

But in particular cases, from the situation of the Vomica, from its size, from the kind and quantity of its contents, or from the state of the surrounding lung, Auscultation gives sometimes less and sometimes more notice of the disease by the sound conveyed in one of these actions than another. One is needed to supply the symptom which another does not give.

Some time ago I was desired to pro-

nounce upon the nature of the disease, in a gentleman who was affected in this manner. He had suffered a long and abiding Hectic, and had reached a state of extreme Emaciation, but had a very slight Cough, and expectorated only one large globule of yellow heavy matter once a day, immediately after he woke in the morning. His little Cough, his little Expectoration, and his ability to inflate his lungs freely and deeply, encouraged a hope that he still might not have Consumption, his abiding Hectic and his extreme Emaciation notwithstanding.

I examined the chest, and found the Respiratory Murmur clear and loud, and vesicular. In the act of Breathing there was no unnatural sound, either Cavernous or Gurgling, any where.

Having learnt thus much, or rather, having puzzled myself thus far, I was interrupted in my further examination by some accident, and I postponed it until the next day,

The next day I could get no more information from the mere Breathing, except that, upon the whole, the air entered more freely into one lung than the other, the other, how ever, not wanting the Vesicular Murmur in any part. Neither from the Voice could I get more information; it was neither Cavernous nor Pectoriloquous. Percussion elicited a somewhat different sound from the space between the clavicle and mamma on one side and the other. But the sound was dull on neither side.

What, however, neither the Respiration nor the Voice could declare by any authentic sign, was made clear and manifest by the act of Coughing; viz. that there was a large Cavity full of fluid occupying a space in one lung between the clavicle and the mamma. For when I desired the patient to make as deep an inspiration as he could, and then to Cough with all the force he was able, instantly there came Plash after Plash against my ear from the whole of this space, a sound which could only result from the agitation of fluid in a large Cavity.

But why was there Vesicular Breathing at this space? Probably because the Cavity, large as it was, had a considerable stratum of healthy lung interposed between it and the walls of the chest. Why was there no Pectoriloquy? These same conditions, the size of the Cavity, and the intervention of healthy lung between it and the walls of the chest, were enough to prevent it. Besides, the Cavity was full, and thus was unfavourable to Pectoriloquy.

And why, above all, was there no Gargouillement, no Gurgling sound in the Respiration, and little or no Expectoration? The air during ordinary Respiration might not have free access to the Cavity. The Cavity was there, but there might be no considerable bronchus entering it. Or, what is most probable, a considerable bronchus or bronchi entered it, but were obstructed by some obstacle, from within or from without, before they reached it. Either hypothesis will furnish the explanation, how a large Cavity full of pus can exist in the lungs, and yet not enough of air find its way *into* it, in ordinary Breathing, to produce an Audible Agitation of its contents, and not enough of matter find its way *out* of it to furnish more than a scanty Expectoration. In this case it took the whole night, and the continual oozing of pus by some narrow passage from the cavity into the Bronchi, to accumulate half an ounce ready to be expectorated in the morning.

So much for the present. But you must inquire further into the Forms and Stages of Phthisical Disease, if you would know the real value that belongs to the Auscultory Signs in question.

OBSERVATIONS AND RESEARCHES

ON

A NEW METHOD OF CURING CANCER.

By Alexander Ure, M.D., M.R.C.S.

Late House-Surgeon to the Royal Infirmary at Glasgow.

[Concluded from p. 394.]

The four following formulæ are given by Dr. Canquoin for preparing the phagedenic paste. The first three possess strength in proportion to the numbers 3, 2, 1; and the fourth, which is endowed with a peculiar property, will form hereafter the subject of special notice.

I. Chloride of zinc one part, wheat-flour two parts.

II. Chloride of zinc one part, wheat-flour three parts.

III. Chloride of zinc one part, wheat-flour four parts.

IV. Chloride of zinc one part, chloride of antimony half a part, wheat-flour two parts and a half.

Twenty-four to thirty drops of water are to be added for each ounce of chloride.

The preparation of the phagedenic paste requires the utmost care and attention; hence, to procure it properly the following instructions must be scrupulously followed. The chloride of zinc, reduced to powder, is to be mixed, as quickly as possible, on a slab, with the

given quantity of flour. One half of the mixture is immediately to receive its proportion of water, and to be worked up progressively with a spatula, until it forms a homogeneous paste like honey. This paste is to be brought to the desired stiffness by trituration with the remainder of the dry ingredients, well beat for a few seconds, and then rolled out into cakes or wafers, of from half a line to four lines in thickness.

The quantity of water must be proportionally augmented, according to the increased amount of flour in the second and third formulæ.

The antimonial paste, No. IV., is to be moulded into a crayon shape; because, as it preserves constantly the consistence of soft wax, a suitable thickness can always be given to it, so as to adapt it to the form of certain cancerous tumors, presenting inequalities of surface.

As, however, the flour employed in the above formulæ consists of starch, gluten, and vegetable albumen, it will produce a complex combination with the chloride in the phagedenic paste, which may blunt or interfere with its erosive action; or possibly undergo some fermentative change when applied to an ill-conditioned ulcer, and the viscidity of the compound give rise to more or less difficulty in the manipulation. It therefore occurred to me, that if some inert inorganic powder were substituted for the vegetable matter, capable of absorbing and retaining a sufficient quantity of moisture to form a paste, which should be a simple mechanical admixture, it would then be possible to turn to account the full escharotic powers of the chloride. The anhydrous sulphate of lime, in impalpable powder, will be found to realize the above conditions. Mixed with the chloride of zinc, in the proportions already indicated, a paste like putty may be obtained, after these have been well incorporated together with a few drops of water*.

The paste so prepared is perfectly plastic. In its composition the calcareous sulphate seems to perform the part of a porous medium, which allows the escharotic gradually to exude into the morbid texture. In proportion as it is abandoned by its deliquescent ingredient it acquires a firmer consistence, until at length it becomes concrete, and constitutes an impervious case for the eschar. I have already employed it in practice, and have found its corrosive properties to act effectually and beneficially in this form.

Manner of using the Phagedenic Paste.

Where the integuments are sound, the epidermis should be removed by means of a blister; and on the following day one or other of the above preparations, corresponding to the thickness of tissue to be destroyed, is to be applied to the cutis of the diseased part. The sensibility of the surface must also be considered; for should it possess but a feeble degree of vitality, the most powerful form is to be preferred.

The paste No. I. four lines thick, applied during four days, is capable of producing an eschar of from one and a half to two inches in depth. The same paste, three lines thick, applied during three days, will furnish an eschar of one inch at least in depth; the same compound, two lines thick, will in two days determine an eschar of not less than half an inch. The paste No. I., of one line, will yield, in twenty-four hours, an eschar of three lines. Finally, the paste No. I., of half a line, will produce, in the same time, an eschar of at least one line.

These changes will manifest themselves with the above precision only on tissues endowed with a considerable share of sensibility, and of which the consistence is nearly normal. In the gristly (lardacé), almost fibro-cartilaginous degeneration, about one-third is to be deducted from the thickness of the eschar above mentioned.

No. II. is employed in cases of cancerous ulceration and superficial carcinoma, which are attended with much pain.

No. III. is eligible in every species of cancerous affection, occurring in nervous subjects who are incapable of supporting the violent pain which the preceding more concentrated escharotics might occasion. It is so much less productive of suffering, as it is slower in its action.

Lastly, the antimonial paste is best adapted to nodulated cancerous tumors, for which a more decided escharotic action is required.

These preparations, applied over a denuded surface, excite, in a few mi-

* Special care must be taken to prepare a pure sulphate, by calcining the crystallized gypsum at a gentle heat in an oven; for the Paris-plaster of the shops is often sophisticated with chalk or whitening, which would immediately decompose the metallic chloride, and impair its qualities in a greater or less degree.

nutes, a feeling of heat, which, ere long, rises to a burning heat; which unpleasant symptoms may be relieved by an opiate enema.

When the operation of the paste is complete, it may be gently taken off, and the eschar covered with an emollient poultice until its separation, which usually happens, as formerly stated, from the eighth to the twelfth day, according to the thickness of the layer employed. The application is to be repeated again and again, till the whole morbid structure is removed; after which the surface is to be treated with simple digestive ointment; or, in case of acute cancer, with cataplasms, until the cure is finished.

In certain modifications of carcinematous tumors that are voluminous and prominent, Canquoin, instead of applying the caustic on the anterior segment, surrounds the base with a ring of paste two lines broad and four deep.

Should the carcinoma present a central depression, its destruction may be accomplished by using the phagedenic paste in a spiral form.

The chloride of zinc will probably form a valuable means of curing incipient cancerous ulcers of the uterus. These, in their early stage, may be looked upon as purely local affections, since Bayle has demonstrated, by numerous dissections, that the tissues of the organ are perfectly sound at the distance of two or three lines above the solution of continuity. In some instances it is reported that they have been healed by the topical use of the acidulated nitrate of mercury, as also by the caustic potash: but as both have been objected to in practice, the former from its tendency to spread over the healthy parts and excite inflammation, the latter because it is too uncertain in its effects, corroding too profoundly, and giving rise to fatal inflammation, amputation of the cervix has come to be regarded, by many, as the sole alternative for eradicating the disease. Now, the chloride of zinc, liable to none of the inconveniences that have been imputed to these other caustics, employed in its most concentrated form, will furnish its characteristic dry, easily definable eschar, destroying the morbid parts, and leaving behind a healthy surface, which will rapidly cicatrize: thus saving the patient the necessity of submitting to an operation which, although unaccompanied by much pain, is yet most repugnant to her feelings.

Cauterization with the chloride must likewise prove advantageous in carcinomatous affections of the tongue, lips, and of the rectum, where arsenic, from its powerful poisonous qualities, is totally precluded.

The following ointment is recommended for effecting the destruction of extensive schirrhous surfaces, previously flattened by long-continued methodical compression, as also of certain dense scirrhi. This has been technically named, the resolvent pomade.

Take of oxygenated pomade, prepared by triturating eight parts of boiling axunge with one of nitric acid, one ounce; melt this by a gentle heat, and add to it three drachms of the acid subdeuto-nitrate of mercury. Increase the heat a little, till the nitric acid become decomposed, so as to peroxygenate the pomade, and bring the salt into intimate union with it. The ointment, when well prepared, is very hard, and of an orange-yellow colour.

Dr. Canquoin describes the case of a woman affected with a schirrhus of one half of the face, who had been previously treated for it, but without benefit; and she seemed doomed to become, ere long, a victim to the frightful malady. However, thirty-five days' application of the above ointment sufficed to work a cure, without the slightest trace being left.

In two or three months time, and even less, a softening and suppuration have been procured of indolent schirrhous tumors, of a violet-red hue, by the following topical application, called the maturative ointment:—

> Take of the acetic infusion of the Bark of Spurge Laurel, ʒiss.; of Molasses, ʒiss.; Olive Oil, ℥j.; Ox Bile, ʒij. Mix together, and reduce, by the aid of heat, to the consistence of an ointment. Withdraw the heat, and add,
>
> Unguent. Basilic. ʒiss.; Cerati fusci*, ʒiss. Mix the whole well together, and incorporate with each ounce a drachm of the subdeuto-nitrate of mercury.

Inflamed cancerous tubercles, superficially situated, have been destroyed by applying to them, for a few days, a solution containing five or six grains of

* Or Onguent de la Mère, prepared with litharge, axunge, butter, and mutton suet, of each 25 parts, yellow wax 18, and black pitch 8.

cyanide of potassium to one ounce of distilled water.

With the external means above enumerated a happy result may be anticipated in the generality of cases. When there prevails a cachectic state, or confirmed cancerous diathesis, or when the carcinoma is voluminous, and has formed a multitude of firm adhesions, or is of long standing, and has occasioned extensive ravages, no reasonable hopes of recovery can be looked for from any mode of treatment.

In every instance of voluminous tumor, removal by the knife must still continue to maintain the preference, as offering a more speedy, and consequently less painful method of extirpation. Indeed, in thick, firmly-attached swellings, the scalpel ought to commence the operation, and the caustic be made to complete the cure. In order to eradicate fungous growths, it is indispensable that they be first of all snipped away, so as to bring the escharotic into direct contact with the roots of the disease.

The secondary indurations, that make their appearance in the vicinity of parts that have been cured, depend on diathesis, and may be attributed to the circumstance of the phagedenic application having been confined to too circumscribed a space.

Without seeking to draw a minute parallel between the comparative merits of the extirpation of cancer by surgical operation and by the caustics in question, suffice it to say, that the latter never create any serious inconvenience, while an amputation of the breast may not always have the most favourable issue. Besides, the knife can in nowise modify the subjacent tissues, it can only eradicate the evil when not deep seated; and hence disease frequently returns after the most dexterously-performed operations.

The internal treatment is of essential importance. That proposed by Dr. Canquoin consists in the administration of small doses of dilute sulphuric and nitric acids, conjoined with some drops of Pearson's Solution*. Of the latter six drops are given at first; the dose is gradually increased up to seventy-two in the course of twenty-four hours.

* Pearson's Solution is made by dissolving a grain of arseniate of soda in an ounce of distilled water.

Where the menstruation is at fault, a syrup containing iron or iodine, or perhaps both combined, is to be substituted for the above.

Much benefit has been derived in cancerous affections from the use of the mineral waters of Hellbrun in Bavaria. the active ingredients of which are iodide and bromide of sodium. It is probable that the mineral spring of Ashby-de-la-Zouch, which abounds in bromide, might prove an excellent remedy, used either alone or conjoined with an iodic preparation.

Dr. Canquoin has annexed several cases in corroboration of the efficacy of his plan of treatment, from which we subjoin the following abstract:—

I.—A female, aged 50, was affected for three years with a cancer of the right breast, five inches in diameter, and an inch in thickness, accompanied with acute lancinating pain and great emaciation. A single application of the paste effected a cure of the local disease, and also of the general ailments, in the short space of seven weeks.

II.—A lady, aged 42, had been formerly affected with an enormous cancer of the right breast, which had been amputated by Dupuytren. A few months afterwards the cancer relapsed. Three isolated tumors appeared in the cicatrix. They were completely obliterated in seven weeks by two applications of the paste.

III.—Madame L. had a large cancer of the left breast, two inches thick, and three and a half in diameter; the axillary glands were enlarged. Two applications were followed by a cure, accomplished in about two months.

IV.—M. le Comte A., aged 86, afflicted for fourteen years with a cancerous affection occupying the left eyeball and its appendage throughout their whole extent, as well as the right temporal region, which had resisted the most energetic treatment. Several successive applications of the paste proved efficacious in curing this horrid affection in sixty-nine days.

V.—Benoit Ordel, aged 76, had a cancer for fifteen years the size of a hen's egg, on the middle of the left cheek, over the duct of Steno. He had

been subjected to a variety of treatment in the Hôpital St. Louis and elsewhere, without any advantage. He was restored to perfect health in twenty days.

VI.—M. D., aged 77, since his nineteenth year had been affected with a cancer the size of a goose's egg, covering the whole temporal region, a part of the eyelids, and of the left cheek. As in the preceding case, various means had been tried in vain; but two applications of the paste proved successful in the course of two months and a half.

VII.—Madame L. had a cancerous affection of the face, of twenty-two years' duration, which had resisted an operation by M. Dubois, and afterwards a variety of caustics. It gave way in the course of a month to the phagedenic paste.

VIII.—Mons. Valerien Vendeuil, affected in the face with a cancer of seven years' standing, which had destroyed the nose altogether, and a great part of the left lower eyelid. After having been treated for several years without benefit at St. Louis, he was finally cured by Dr. Canquoin's method in four months.

IX.—Demoiselle Laurence Prévost, aged 16½ years, for the eight preceding years had been affected with a cancerous affection of the face, which had destroyed the nose in whole, and the upper lip in part. The tongue was perforated throughout its entire thickness, and the pharyngeal region had greatly suffered. This hideous malady had for years baffled the most skilful practitioners, and this young woman seemed devoted to a speedy death; yet she was cured in about five months.

Two cases are related of grave and deep-seated fungus, in which the method failed, as might have been expected.

A case is adduced in proof of the proposition above laid down, that the cure of external cancer will not prolong the existence of individuals who labour under a confirmed cancerous diathesis.

CONCERNING THE DEFECTS AND RESULTS OF ENGLISH PARISH REGISTERS;

AND THE COMPARATIVE INFLUENCE OF DOMESTIC MANUFACTURE, OR FACTORY LABOUR, ON FEMALE MORTALITY.

To the Editor of the Medical Gazette.

Sir,

Having discussed at some length, in my last letter, the degree of accuracy which may be fairly attributed to the several enumerations of population in Great Britain, I have now to treat of the other great branch of our successive population inquiries, which consists of a collection of the baptisms, burials, and marriages, recorded in the parish registers of England. Historically, I may be permitted to say, that, in the year 1801, the number of baptisms and burials in each decennary year (1700, 1710, 1720, 1730, 1740, 1750, 1760, and 1770), was called for by that part of the population inquiry which sought to ascertain "the increase or diminution thereof;" also the baptisms and burials of every year from 1780 to 1800 (both inclusive); and the marriages from 1754, when the marriage act came into force, since which time the accuracy of that part of parish registers is guarded by such precautions as render it unimpeachable. It is scarcely requisite to add, that from the year 1800, the successive population inquiries have obtained parish register returns to the year 1830 inclusive; and on the last occasion, the date at which the register books of each parish commence, was ascertained, and appears in the Population volumes.

From the acknowledged defect in the registers of baptisms and burials, I must be content to circumscribe the inaccuracy within such limit as can be reasonably established; and in such attempts I have always obtained the best illustration by making use of the established division of England into counties, and taking advantage of the particular county which appears best applicable to the subject under discussion. Thus, in shewing the effect of a greater or less increase of population on the classified ages of the existing population*, I

* See Medical Gazette, vol. xvi. p. 270.

contrasted Herefordshire and North Yorkshire with Lancashire and West Yorkshire; and, on the present occasion, I prefer Cornwall to any other county, not only because its parish registers are nearly perfect, but because it consists of an extensive promontory, and partakes of the character of an island, in its separation from the rest of the kingdom. It is a very healthy county, and contains no large towns, which last circumstance is very favourable to the accuracy of parish registers.

The number of children born in England, as compared to the number of marriages, is 441 to 100*; so that 440 to 100 (or, as stated in the Edinburgh Review, $4\frac{2}{5}$ to 1†) may be deemed an unexceptionable estimate. Herein I avoid consideration of second marriages, of still-born infants, and even of illegitimate children; of the latter, not only because Cornwall produces nearly the same proportion as the rest of England, but because the custom in France and elsewhere, of assuming all children to be illegitimate who are deposited in Foundling Hospitals, precludes any just reference or comparison in adverting to legitimate children exclusively; the poverty and misery of married parents too often driving them to the resource of a Foundling Hospital, where such institutions exist.

The power of being able to assume a certain number of children to each marriage, is particularly important in a nation where the marriage register, and no other, is accurate and complete; and hitherto there is no reason for thinking that the proportion is decreasing in England (nor, according to M. Quetelet, in Belgium), although in France it has fallen from 431 to 100 in the year 1818, to 361 in 1830; 16 or 17 per cent.‡ Assuming, in Cornwall, 440 children to 100 marriages, the number of births during ten years (1821-1830) would have been 90,728 from 20,620 marriages; and the registered *baptisms* (with those known to have been omitted) were, in fact, 89,243*—a small deficiency, unworthy of notice; and in proof that the register of *burials* in Cornwall is not materially defective, it appears that the actual increase of inhabitants between 1801 and 1811, was 3684 less than indicated by comparison of the registered baptisms and burials; the increase was greater, 1811 and 1821, by 1603; less again, between 1821 and 1831, by 1401†; all the three variations such as are within the range of emigration and immigration in a maritime county.

The importance of approximating (by such inference as has been described) to the number of actual births and deaths in Cornwall, will not be undervalued, when it is considered that, throughout England and Wales, in the aggregate, one-fourth of the births (24 per cent.) do not appear in the baptismal register, and that nearly 20,000 burials in a year are not regularly inserted‡. The total number of the deceased during eighteen years (1813-1830), whose age is recorded, was 3,938,496§; an addition of one-tenth to which fulfils the presumed number of deaths during the same eighteen years. These deaths, classed according to the ages of the population of 1821 (nearly a middle term in the said eighteen years), afford a competent exemplification of mortality, showing how far it varies in the several counties at various periods of human life, and in what degree the mortality of males and females differs; this last-mentioned comparison being entirely undisturbed by considerations of the increase of population, or of error or defect in the registry, because these sources of inaccuracy must have been equally incidental to both sexes in the same county.

---

* See Medical Gazette, vol. xvi. p. 589.

† See Edin. Review, March 1829, p. 31.

‡ These proportions result from the Table of Mr. Corbaux, p. 144 of his book on *Population, Vitality, and Mortality:* and M. D'Ivernois has investigated this subject with his usual acuteness, in a letter addressed to M. Villermé (October, 1834), on the Movement of Population in France. He has divided the fifteen years (1817-1831) into three quinquennial periods, in the first of which appear 212,814 marriages, 953,638 births; in the last five years (1827-1831), 253,742 marriages, 975,160 births: as 448 to 100 marriages in the first period; as 384 to 100 marriages in the last period—a decrease of 14 per cent., or one-seventh part. The solution of this otherwise increbible decrease of fecundity, is thus given by M. D'Ivernois:—"Mais ce nouvel ordre de choses, fondé sur la convenance et la possibilité de mettre des limites volontaires à la fecondité des mariages, souleve une question d'une si grande delicatesse, que jusqu'ici les economistes les plus hardis n'osent guère y toucher que par des insinuationes detournées!" M. D'Ivernois elsewhere says, that in Geneva (his own residence) the decrease had arrived at 275 births to 100 marriages, or 37 per cent. less than in England, in Belgium, and (probably) in the northern departments of France.

* These numbers are obtained from p. 48 of the Parish Register volume of 1831, by adding seven annually to the number of marriages (for Jews and Quakers), and 3420 to the registered baptisms, at the rate of 342 annually.

† For particulars, see p. 50 of the same Parish Register volume of 1831.

‡ See Population Preface, p. xlv.

§ See Parish Register volume of 1831, p. 487.

Having arrived at this point, I am enabled to offer to your notice what may not be unacceptable in a Medical Gazette, although I confess myself somewhat at a loss as to the best manner of presenting such knowledge to your readers in a striking form, the entire detail of the several counties being too large for insertion; and I must be permitted to preface what I shall produce with a few explanations.

In contrasting the least with the greatest mortality in the several grades of life in the several counties of England, I also insert as a middle term the mortality of all England, which will not appear to be quite the same as that which is stated in a former letter of mine*; and for the following reasons:—That table is calculated on an average of *seven* years, three of them preceding, three succeeding the year 1821, when the ages of the population were ascertained. The statement of English mortality now inserted is calculated on the mortality of the entire *eighteen* years of recorded ages of the deceased, and being nine years on this side of 1821, only eight years anterior to that date, exhibits a higher average of mortality from the increase of population preponderating in the latter period, beyond that in the former and shorter period of eight years. The amount of difference may be seen in the Population Preface of 1831, (pp. xxxviii. to xlii.) being, on an average of eighteen years, nearly as 110,900 males to 108,000; 107,900 females to 105,900 annually during the respective periods: wherefore the mortality, as calculated on the population of 1821, is in that proportion greater, by making use of the higher average of deaths. A further variation of the same tendency arises from the omission of Wales on the present occasion, the Parish Registers there being more defective than those in England; yet the county of Monmouth (sometimes said to be more Welsh than Wales itself) is retained, although so remarkably defective in registry, that the marriages sometimes equal the number of baptisms in its most populous districts. The results of the Burial Register of this county (also very defective) having been inserted without explanation in the Population Prefaces of 1811 and 1821, gave rise to a disquisition unsupported by fact, and which therefore inflicted on me some pain, although such minute explanations are not quite admissible in a demi-official document. Let it now be understood that on the present occasion the results of this county *individually* have not been calculated, although it has been included as part of England, being merged in the mass as a kind of balance (somewhat inadequate) against the unfavourable considerations before described.

In comparing the other counties with each other, it is also to be understood that, for the sake of fair comparison, districts notoriously unhealthy, and several of the largest towns, are excluded from the bulk of some of the counties; and the detail of these exclusions must now be tolerated by those who examine with interest the various rates of mortality in the several counties.

The county of Cambridge is given exclusive of the Isle of Ely, a well-known marshy district, one-third of the entire county. Devon is given exclusive of Plymouth and its suburbs; not so much because Plymouth is a large town, as from the great proportion of migratory male population, constituting the garrison, the seamen of the royal navy there stationed, and mercantile seamen, in common with other ports. None of these can be peculiarly ascribed to Plymouth locally: whence the seeming mortality of males is greatly exaggerated from 10 years of age to 50 or 60; and from 20 to 30 years of age appears twice the rate of female mortality in the same town. The county of Southampton (Hampshire) is given exclusive of Portsmouth and its neighbourhood, for the same reason. Gloucester is given exclusive of Bristol. The county of Lancaster is given exclusive of Liverpool, the mortality of which is exceptionable, as the resort of many seamen, foreign as well as native; but Manchester, and the other large towns of this populous county, are not excluded, lest unfairness should be imputed to the calculation by those who maintain the unhealthiness of our manufacturing population. The West-Riding of Yorkshire is given exclusive of Leeds, but including its other populous towns, so as to make a fair comparison with Lancashire. The county of Lincoln is given exclusive of the parts of Holland, and the county of Norfolk exclusive of Lynn and its neighbourhood, both these districts adjoining the Isle of Ely (before mentioned), and liable to the same deleterious influence in a minor degree.

* See Medical Gazette, vol. xvi. p. 271.

The city of Norwich is also excluded from the county of Norfolk, so as to leave only an agricultural population for comparison with the adjacent counties. The county of Northumberland is given exclusive of Newcastle-on-Tyne, a port and also a large town. The county of Nottingham is given exclusive of the manufacturing town of Nottingham. The county of Surrey is given exclusive of Southwark, which (as regards mortality) is the worst part of the metropolis; yet the populous parishes adjoining the Borough of Southwark operate unfavourably in estimating the mortality of Surrey. The county of Middlesex is omitted as a county, being almost absorbed in the metropolis. The county of Warwick is given exclusive of Birmingham. The East-Riding of Yorkshire does not include the City of York, nor the port and populous town of Hull.

TABLE *exhibiting the Lowest and Highest Rate of Annual Mortality, in twelve specified grades of human life, in the several Counties of England; exclusive of Wales and of the County of Monmouth.*

I.—Annual Mortality under Five Years.

Males.	one dies in	Females.	one dies in
Hampshire	29	Hampshire	34

XII.—Annual Mortality (90—99) during Ten Years.

Males.	one dies in	Females.	one dies in
Dorset	4·1	Dorset	4·4
Lancaster	3·7	Huntingdon	4·0
England	2·8	England	2·9
Hereford	1·8	Hereford	1·5
Westmorland	1·2	Cambridge	1·3

The foregoing table cannot be carefully inspected without perceiving that the mortality of England, in the aggregate, approaches unfavourably to the greatest mortality attributed to any of the counties,—an appearance which would invalidate the average ascribed to England, unless it be considered that the omission or withdrawal of the metropolis and many other large towns (as previously stated) cannot but produce an effect of this kind; so that if the mortality of the metropolis and of such towns had been stated, this seeming inconsistency of the table would disappear; but I have avoided this kind of justification, from a natural repugnance to produce local anxiety or discontent, which would do more harm than good. I will only say, that the inhabitants of the metropolis may rest assured that they have no reason to be dissatisfied with the degree of longevity (that is, of health) which they enjoy.

It has already been been shown (page 585 of your last volume) that in the several grades of age, the expectation of female life is preferable to that of male life; yet on dividing the mass into its component parts (England into its counties) the advantage in five instances rests with the male sex, and in as many others is nearly balanced. The time of life at which female mortality greatly predominates in four of the five unfavourable counties, is from 10 years of age to 20; and this so remarkably, that perhaps you will admit a tabular illustration, such as may enable your readers to contrast these four counties with England in the aggregate, and with certain other counties.

Counties.	Age 10 — 14.		Age 15 — 19.	
	MALES.	FEMALES.	MALES.	FEMALES.
—	One dies annually in	One dies annually in	One dies annually in	One dies annually in
Bedford	195	147	157	97
Bucks	241	155	160	106
Northampton	226	142	168	103
Rutland	265	188	199	132
—	—	—	—	—
Average of Four Counties	232	158	171	109
ENGLAND	211	201	147	138
Lancashire	195	210	135	134
West York	208	213	148	142

Thus the mortality of females in the two grades III. and IV., from ten to twenty years of age, is as 100 to 66 (three to two), on the average of the four first counties; as 100 to 95 (five per cent.) in all England; as 100 to 104 in Lancashire, where the scale is thus turned in favour of the females to the extent of four per cent.; in West Yorkshire the mortality of the sexes in these grades of age appears to be equal.

I never yet could discover any fact which was likely to place the health of the manufacturing population below that of other occupations; nor have I ever met with any alleged fact to that effect which stood the test of strict examination; so that in the conflict of opinion I was bound to adhere to equality of health in the grades of female life [10-14 and 15-19] which chiefly constitute our manufacturing population. Moreover, I was the less prepared to discover disadvantage to young females in the counties of Bedford and Bucks than elsewhere, because in my youth I had traversed those counties oftener than once in pedestrian excursions, and was then much struck by the happy appearance of young girls and other females sitting at cottage-doors or with open windows, busied in lace-making; especially as constant shelter from bad weather had preserved their beauty, so as to equal that of highly-educated females. Since that time lace-making

has been seized by the inventors of machinery; but straw-platting for female hats has taken its place in those counties, where the tuition of young children in reading and writing, and straw-platting, is often mixed together at evening schools. I was greatly surprised, therefore, at discovering the stubborn fact of disproportionate mortality in the females of these and the two other counties; the more so, as Hertfordshire, Oxfordshire, and Berkshire, adjoining counties which partake of sedentary domestic occupation, exhibit similar mortality in a less degree *.

It is impossible to investigate retrospectively, whether in earlier times, in the days of Queen Elizabeth for instance, the sedentary occupation of the *spinster* (which included all unmarried females, and is still their legal designation) had the same deleterious effect as in the four selected counties: if so, females are positively benefited, not injured by the introduction of machinery, as well-meaning philanthropists too readily suppose. For I cannot imagine or believe that regular hours of labour, plenty of fuel, good clothing, and the many other comforts which spring from high wages, are injurious to the health of any human being. We all know but too well, from the incessant clamour of hand-loom weavers, that there are many industrious men, who during a series of years have carried on a domestic manufacture, in small rooms crowded by looms and weaving apparatus, breathing air loaded with dust, their hours of labour extending into the night, payment for such weaving very moderate,—preferring all these inconveniences to factory labour, because they cannot endure stated hours, and the regular behaviour indispensable in every factory: nor do they send their children thither, because they are retained at home to prepare hand-loom work. When power-looms were first invented, the consequent hardship on existing hand-loom weavers justly created general commiseration; but plenty of time has now intervened for equalizing the reward of similar labour. Hand-loom weavers, however, are not yet convinced that in preferring liberty to subordination they secure a reward which cannot be expressed in money value, and that they cannot reasonably expect independence, and at the same time money payment equal to that of regular workmen in a factory.

The fifth county in which female mortality exceeds that of males is Westmorland, of which I shall only say, that the difference is nothing between 10 and 15, and not striking from 15 to 20 years of age. The four other counties, Bedford, Bucks, Northampton, and Rutland, adjoin each other from south to north, and afford a mass of 300,000 or 400,000 human beings producing a similar and remarkable result in those two grades of life. Those who possess the Population volumes of 1831 may readily satisfy themselves of the general truth of the fact, by adding the male and female deaths (10 to 20 years of age) at the end of those counties: for exact calculation the corresponding enumeration of ages in 1821 must also be taken into account.

A question will naturally arise in the minds of those who are unaccustomed to considerations of the expectancy of human life, Why is the annual mortality of each county withheld; some of the component parts thereof having been adduced? To this I must answer, that the error produced by the increase of population in each component portion or grade of life, is not unmanageable by such approximation as is fairly allowable, correction and regulation being always at hand, in the annual mortality of the next grade; and this, assisted by the actual number of recorded deaths in each *year* of life, is so effectual in calculating the expectancy of life, that no valid objection can be urged against the result obtained. But the proportion of annual mortality as compared to the existing population, is governed much more by the increase of population than by air or climate, or any other consideration. Such a calculation, however, must take into account the average duration of life in each county (*Vie Moyenne*), which in all England is about 33 years, and would be 42 years, (40·5 the males, 43·7 the females,) had no increase of

* I learn from a book recently published (Southey's Life of Cowper) that the unhealthy effect of lace-making in the northern part of Buckinghamshire (and consequently in Northamptonshire) had been observed by others long since. "Cowper has made Olney and its neighbourhood poetical ground. The town, which is the most northerly in Buckinghamshire, consisted of one long street. Lace-making was the business of the place, a sedentary and unwholesome employment." And in a note it is said, "Mr. Lysons observes, in his Magna Britannia, that persons travelling through the counties where this manufacture prevails, have been struck with the sickly appearance of the women and children employed in it."

population occurred during the life of man retrospectively; in which case the annual rate of mortality, the *vie moyenne*, and the expectation of life at birth, would all have coincided.

I endeavoured to illustrate the effect of the increase of population on the *vie moyenne* at the end of the Popul. Pref. p. liv.; but in an official document circumstantial explanation was not allowable; and I may perhaps hereafter endeavour to elucidate in detail this seemingly novel principle, on which the comparative mortality of nations, as well as of counties, mainly depends.—I remain, sir,

Your obedient servant,

JOHN RICKMAN.

Dec. 14, 1835.

P.S.—I stated with due diffidence, page 587 of your last volume, certain facts which seemed to indicate a remarkable degree of mortality at the age of 84. It has since been observed to me, that the printed formula distributed for insertion of the ages of the deceased, ceases to be continuous at 84 (see page xxvi. of the Population Preface), which may have been the mechanical cause of this seeming intensity of mortality. The question will hereafter be solved by altering the printed formula for the next decennial Return of Parish Registers.

ON THE

SOURCES OF THE VITAL POWERS,

AND THE

RELATIONS THEY BEAR TO EACH OTHER.

By DR. PHILIP*.

To the Editor of the Medical Gazette.

SIR,

IN a former paper I pointed out what appears, from direct experiments, to be the nature of the powers of the more perfect animals. In the present paper it is my intention to consider the sources of these powers, and the relations they bear to each other. These two papers will comprehend a summary of all the general deductions from my experiments; and may, in future, prevent opinions being ascribed to me which I not only never entertained, but took much pains to refute.

THE sensorial organs, as appears from what has already been said, are confined to the central parts of the nervous system; the functions of which, having nothing in common with the properties of inanimate nature, cannot directly cooperate with it; but by the intervention of three sets of organs they are enabled to do so indirectly.

The nerves of sensation and the nerves of voluntary motion, both of which, being vital organs, are, on the one hand, enabled to co-operate, the one directly, the other through organs belonging to the central parts of the nervous system properly so called, with the immediate organs of the sensorial powers; and on the other hand, with the external world, in consequence of the relation they bear to that world; the one being capable of receiving and propagating to the immediate organs of the sensorial powers the impressions made by agents belonging to inanimate nature; and the other, through the medium of the central parts of the nervous system properly so called, enabling the organs of the sensorial powers to impress those agents.

Distinct from all the foregoing functions are those by which their organs are maintained, thence termed the vital functions; the immediate agents in which are the ganglionic nerves (each conveying the influence of all the central parts of the nervous system properly so called, which are distributed throughout every part of the brain and spinal marrow, the organs of the sensorial powers being confined to certain parts of these organs), and the blood, equally with the nerves themselves, endowed with vital properties. The former derive their power from the central parts of the brain and spinal marrow, with which they are associated, namely, the only active parts of the nervous system pro-

* Mr. J. W. Earle has been so polite as to send me a copy of a letter which he had addressed to the Editor of the Medical Gazette, for insertion in the next number of that journal. I am at a loss to understand how Mr. Earle has fallen into the mistakes he has committed. The paragraph, part of which he quotes from my last paper, was sufficient to have prevented them. When I first made the experiment, the apparatus for applying the voltaic electricity was arranged after the nervous influence was withdrawn. Even the time required for this I found slightly impaired the structure of the lungs. When the apparatus was previously arranged, and the electricity applied as soon as the nervous influence was withdrawn, their structure was found as entire as in the healthy animal, and they continue perfectly healthy till the inflammation comes on, which requires many hours. What does Mr. J. W. Earle mean by his comment on the quotation above referred to. Can he be so little acquainted with the subject as to suppose that all degrees of impaired structure of the lungs implies the death of the animal? With regard to the cause of death when voltaic electricity is employed, I have both in my last paper and elsewhere stated, that it is the consequence of inflammation of the lungs excited by the electricity, which proves fatal more quickly than the partial abstraction of the nervous influence.

perly so called; the latter from its own composition; that composition, like the structure of the solid organs of our bodies, depending, more or less immediately, on all the general powers of our frame,—its own powers, the sensorial, the nervous, and muscular powers, and the relations these powers bear to each other.

The vital functions, properly so called, are all, we have seen, of a chemical nature; their immediate agent is supplied by the central parts of the nervous system properly so called, the same which operates in all other chemical changes, its effects being modified by the properties of life.

Thus there are, in the more perfect animals, two systems, in a great degree distinct from each other, to the maintenance of both of which the sensorial, nervous, and muscular powers, and the powers of the living blood, although in the two systems employed in very different ways, are equally essential; namely, the sensitive system, by which we are rendered capable of enjoyment, and on which our intercourse with the external world depends; and the vital system, by which the due structure of the organs of all our functions, whether sensorial, nervous, or muscular, and the due composition of the living blood, are maintained.

The only connecting link between the functions of these systems is the function of respiration, because it is the only vital function to which the sensorial powers are necessary; respiration ceasing, provided the due supply of air be not withdrawn, only when sensation ceases; or the effect of which, in producing, through the function of volition, the necessary expansion of the chest, is by some cause prevented. Thus it is that the failure of respiration is, *in all instances*, the immediate cause of death: for the sensorial functions are *always* the first which wholly fail; although, in natural death, that is, the death of old age, and in most other forms of death, the failure begins in the nervous and muscular functions. I speak of what, in common language, is called death, which is the consequence of the removal of the sensorial powers alone; for the vital powers, and all their functions, with the exception of respiration in consequence of its partaking of the sensorial powers, it has been found by direct experiment, survive the removal of those powers.

The cause of the vital powers being the first which begin to fail is, that their organs are immediately exposed to the operation of the inanimate agents on which all the phenomena of life more or less directly depend; and which, by their continued operation, tend constantly to exhaust the excitability of the organs to which they are directly applied. And the cause of their being the last which wholly cease is, that a certain vigour of the vital being necessary for the maintenance of the sensitive powers, the latter necessarily cease before the total extinction of those which maintain them; which are still maintained by their usual stimulants, the removal of the sensorial powers not immediately preventing their continued application.

The sensorial powers are subject to imperfect and temporary exhaustion, the effect of the various excitements of the day, which constitutes sleep; of which state the vital powers in no degree partake, although they, to a certain extent, feel its effects. The latter are subject to complete and permanent exhaustion, the effect of the stimulants of life, and the cause of the death of old age.

The death of old age is a rare occurrence; for in old age we become so liable to disease, that extremely few die, alone, in consequence of the continued operation of the functions of health.

The last of the chain of the remote causes of the death of old age is sleep; because, during sleep, the frequency of respiration being, in consequence of the impaired sensibility, lessened, and all the vital functions, on this account, less powerfully excited than in our waking hours, respiration is most inclined to fail, the excitement to respire being proportioned to the degree of sensibility and the excitement of the vital functions.

It appears, from all I have had occasion to say, that in the maintenance of all the organs, both of the sensitive and vital system, there are four distinct species of powers employed, the sensorial, the nervous, and the muscular powers, and the powers of the living blood. These powers, it appears, from a great variety of experiments, have no direct dependence on each other; yet each an indirect dependence on the other three, the healthy structure or composition of the organs of all depending immediately on the nervous and muscular powers, and the powers of the living blood, and more remotely on the sensorial powers.

The muscular power remains for a certain time after the removal of the sensorial and nervous powers, and the powers of the living blood; the vital powers of which, in part at least, also remain after it is deprived of the influence of all the other powers, because they are found to exist for a short time after the blood is removed from the body. The sensorial and nervous powers survive each other; but neither can survive, except momentarily, the loss of the blood, or of the muscular power by which its supply is effected*. We can have no doubt, I think, from the facts stated in a paper published in the Phil. Trans. for 1831, and republished in my Treatise on the Nature of Sleep and Death, that the active power of the vessels, like that of the heart, is a muscular power.

The muscular power not only survives the sensorial and nervous powers, and the powers of the living body, but is capable of its functions after they are withdrawn, as appears from the effects of artificial stimulants†.

All the functions of the nervous remain after the removal of the sensorial power, with the exception of those in which the latter power co-operates with it.

The sensorial functions also remain after the removal of the nervous power, for the short time that life can continue after the loss of this power, with the exception of those in which these powers co-operate.

It appears from the whole of the foregoing facts, that the source of all the vital powers is in the mechanism of the organs to which they belong; they are therefore inseparable from those organs.

While all the powers of the more perfect animals are entire, the muscular, notwithstanding its independence of the nervous power, is immediately subjected to its influence, even to the extent of its total extinction when the cause impressing the former is both powerful and sudden. And the same, it would appear, from the circumstance of the blood not coagulating when an animal is suddenly killed, by a cause capable of powerfully affecting the nervous system, is true of the vital powers of that fluid. And the nervous, notwithstanding its independence of the sensorial power, is in like manner, and to the same extent, subjected to this power; which, through the medium of the nervous power, has also the same influence over the muscular power: and we have reason to believe, from the general laws of the animal economy, (although, as far as I know, the fact has not been ascertained either by direct experiment or observation,) also over the vital powers of the blood.

Thus the powers on which the maintenance of the sensorial, as well as all the other organs of the living animal depends, are subjected to the sensorial power, on which depends the great influence of mental affections both on the functions of health and the progress of disease.

In the foregoing statements nothing was left to conjecture. In my Inquiry into the Laws of the vital Functions, and papers published in the Philosophical Transactions, the proofs of each, resting either on undisputed experiments or observations open to all, will be found.

I am, sir,
Your obedient servant,
A. P. W. Philip.

Cavendish-Square, Dec. 14, 1835.

* I speak here only of the manifestation of the sensorial powers in the animal body, disclaiming all intention of entering on any question respecting either the nature of these powers, farther than relates to their influence on the functions of the animal frame, or their mode of connexion with that frame; questions the discussion of which their nature, independently of the ample experience we have had, might have told us, is neither consistent with the sources of our knowledge or the nature of our minds.

† The heart and vessels are excited by inanimate agents, the stimulating ingredients of the blood. We know that it is the stimulant ingredients, not the vital properties of this fluid, which it possesses for other purposes which I have elsewhere had occasion to point out, which excite the heart and vessels; because, when these ingredients are separated from the blood they have the same effect on the muscular fibre.

QUESTION WHETHER VITALITY IS EITHER IMPARTED OR SUSTAINED BY GALVANISM.

To the Editor of the Medical Gazette.

Sir,

I take advantage of the opportunity afforded me by the present discussion between Drs. Philip and Williams respecting the identity of voltaic electricity and nervous influence, to propose a

question to the former of these gentlemen, arising out of a circumstance mentioned in the experiments which are most remarkable among those which he adduces in support of his opinions on this subject. The circumstance here alluded to is the fact, that in all the comparative experiments (that is, in all those in which two animals were taken, the nerves being divided in each, but one only subjected to the action of galvanism, the other being left undisturbed, for the purpose of comparing the appearances in each together), death always took place several hours sooner in those animals which were treated with galvanism than in those which were not subjected to the influence of this agent. It seems fair to conclude from this fact, that if voltaic electricity and nervous influence be identical, the application of galvanism ought to restore that which is lost by the division of nerves, and, consequently, that the galvanised animal, instead of dying several hours sooner, ought to live considerably longer than one which has not this advantage.

How, then (and this is the question I would propose for Dr. Philip's consideration), is this fact compatible with the conclusion respecting the identity of these two powers? It is the more necessary that our attention should be directed to and fixed upon this circumstance, and the question connected with it, until a satisfactory explanation shall have been rendered; since not only does it appear to have been forgotten by Dr. Philip himself, but in his last communication he assumes directly the contrary to be the fact.

He says (page 397), "when electricity is substituted for nervous influence, as we cannot apply it in the way in which it is applied by nature, it at length (that is, *long after their structure would have been impaired, had electricity not been employed*) excites inflammation, and the animal dies of inflammation of the lungs," &c.

In this passage Dr. Philip assumes it as a fact, that in a comparative experiment, the galvanised animal lives much longer than one not so acted upon; and if electricity and nervous influence be identical, such ought unquestionably to be the case; because it would be immaterial, except so far as it would be impossible to make amends completely by art for the loss of the natural supply, by which of these two powers life was maintained. It is the very essence of a mistake that the person committing it does it unknowingly, and consequently it is necessary that it should be pointed out to him. I beg, therefore, to refer Dr. Philip to his own experiments, particularly to Experiments 77 and 75. In the former of these the "galvanised dog lived only *two hours and a quarter*, while the other was alive at the end of *four hours* after the nerves had been divided, and *then was killed*." In the latter, "when the *galvanised rabbit died*, the other rabbit, which had been *left undisturbed*, *was killed*." In these experiments, which agree with those of other inquirers, we thus find the fact, as actually stated by Dr. Philip himself, to be directly the reverse of that which he has assumed in the preceding passage, which I have extracted from his last communication to the Gazette.

The circumstance to which I have here alluded—viz. the speedy death of animals which are galvanised after the division of the eighth pair of nerves, has certainly not yet been explained, nor even alluded to as a matter of moment, in any part of Dr. Philip's various writings, nor, so far as I know at least, has the question arising from it ever been raised by any one else. In the forthcoming statement of his opinions, however, which he has promised to the Gazette, Dr. Philip will have an opportunity of shewing, if it be possible, how this circumstance can be reconciled with his conclusion respecting the identity of galvanism with nervous influence. Any farther observations, therefore, at present, would be superfluous.

I am, sir,
Your obedient servant,
J. W. Earle.

OBSERVATIONS

ON

ARTERIAL POWER IN HEALTH AND INFLAMMATION.

To the Editor of the Medical Gazette.

Sir,

I should feel obliged by your giving the enclosed paper insertion in the

Medical Gazette, if it meet your approbation.—I am, sir,

Your obedient servant,

J. Slade, M.D.

Barnstaple,
Nov. 26, 1835.

The opinion current among physiologists, that irritability and contractility are properties of muscle *only*, is not, I think, one of the best proofs of their having given the subject the consideration it deserves. To fibrin, that supposed essential ingredient of muscle, I, in opposition to many, attach but little importance, believing it to have no more connexion with these properties than have other component parts. The true source of irritability and contractility is life, which is quite different from the structures of our bodies, or any qualities that may be supposed to belong to any part of the material kingdom; and whether an artery has or has not such constituent parts as are common to the muscle, there are certainly properties which enable it to contract, to be elastic, irritable, and sensitive; but the impulse given to an artery by the action of the blood is almost or quite sufficient to give it motion, even if there were no vitality, or if it were nothing more than an inert yielding tube. The arteries have many coats or tunics, and no particular one or two, which may be supposed to be muscular, can reasonably be considered to assist the motion of the blood independently of the others. That one coat may be better constructed for this purpose than another, and one be more elastic than another, is possible; but to the division of the coats into irritable, muscular, and elastic, some degree of vagueness applies. The whole tube is elastic, contractile, sensible, irritable, and capable of adapting itself to existing circumstances, the contractile disposition being comparatively greater in the smaller branches. That arteries are muscular, is a subject upon which much difference of opinion exists; but that they obey laws, possess nerves, and are influenced by similar stimuli to the muscle, is too evident to admit of dispute; yet the instance of their being acted upon by stimuli is a weak argument in favour of their muscularity; and nothing more fully exemplifies the truth of these nerves being unnecessary to the existence of such properties, than that, when all communication is cut off between them (the nerves) and the arteries and muscle, uninterrupted action is still continued; at the same time it has been shown by experiment that on stimulating the nerve, or even the spinal marrow, in a recently-dead subject, the muscle or artery which is supplied with branches from either of these sources is thrown into motion; this, however, is no evidence that the capability of an organ to act in a living subject is not derived from the principle of vitality. Haller may talk of his vis insita, but he could never prove the existence of an inherent power of muscle, or of any other animal organ, capable of carrying on the functions independently of a pervading principle different in nature from them; nor is the fact of brainless beings a proof of any such inherent power, for in these beings is life. It must be acknowledged that the brain can neither vitalize nor think; and it would be as absurd to talk of any function accruing from that organ as possessing an *inherent* power capable of producing such function, as from any other material body. "The motion of the blood," says Dr. W. Philip, "is carried on independently of the nervous system;" and that it is so of the will is more evident. Involuntary acts result more particularly from life, and voluntary acts from the mind, which wills to action: the former has been said to take place independently of the nervous system, the latter to be the entire result of that system. That there is greater irritability belonging to the organ which acts involuntarily, that it is likewise more readily influenced by stimuli, and that some unusual cause must at all times be in operation to excite to an unnatural degree the organs of involuntary motion, cannot be doubted; all of which must be ascribed more or less to the strong connexion subsisting between these organs and the nerves, which nerves appear to be peculiarly designed to conduct or possess some certain mental and vital qualities. Hence we would infer, that although the natural motions of an artery are independent of the will, they are liable to be influenced by the nerves. How the influence is communicated—how joy, anger, grief, or any inordinate passion of the mind, should expedite the motion and impair the functions of any organ which, in health, is not subject to voluntary power, or requires not the interference of the will, it

is impossible to describe; and in reference to what I have said respecting involuntary acts being more particularly from life, and voluntary acts from mind, many arguments may be adduced to prove that the general physiological principles on this point are liable to some objections.

Galen, J. Hunter, Philip, Hales, Hastings, Thompson, Bell, and Munro, have written much in favour of the muscularity of arteries; while, on the other hand, White, Portal, Richerand, Scarpa, Soëmmering, Bichat, Macfayden, Parry, Magendie, Johnson, and Bostock, have declared the reverse to be the case, many of whom describe the pulse to result entirely from the impulse given to the artery by the current of blood, and others deny the existence of a contractile power. Dr. Johnson considers an artery to be a contractile body, and capable of acting on the blood without muscularity; and the definition Mr. J. Hunter gives of elasticity is, that "it is a continual action, and its immediate effects are produced whenever the resistance (contractility) is removed, by which it may be distinguished from other powers." The elastic power is always at rest in the event of the contractile power being in exercise, and the artery being collapsed; but death may be said to destroy the tonicity of an artery without affecting its elasticity, which would imply that the contractile power is derived immediately from life. In the time of dilatation, or the elasticity being in exercise, there is a supply of blood that appears to stimulate the artery to offer resistance, and contraction upon the contents is a necessary result; which task being completed, the artery seems at rest, or suffers momentary relaxation, or a suspension of contractile power; and this being directly followed by a fresh supply of blood, the calibre increases, the artery becomes more fully injected, and contraction again takes place.

The powers which belong to the arteries are unquestionably given to assist the passage of the blood; and considering the comparatively small force with which that fluid is thrown from the heart at every systole into the aorta, and also the circuitous route of the arterial system, it is impossible to be otherwise. Borelli estimated the power of the heart in propelling the blood at one hundred and eighty thousand pounds weight; but Dr. Black, an able experimentalist, has said, with much accuracy, that this force is equal only to three pounds on the square inch; and it is supposed that double this force, or six pounds on the square inch, would be required to produce a continued stream of water through a tube one-hundredth part of an inch in diameter; which capacity hardly exists in arteries, and therefore, as Dr. Black observes, "the comparative calibre of the small arteries or capillaries must be ten times short of that extent; and the viscidity or comparative glutinous state of the blood requires four times the power water would to pass through a tube of the same calibre and extent." According to Dr. Parry, arteries undergo neither dilatation, nor contraction, nor locomotion of any sort, during the systole and diastole of the heart; but his argument against the muscularity of arteries is no support to the premises from which he draws this conclusion. I agree with him, however, that a pulsation is not indicative of an artery being composed of any constituent qualities of muscle.

That an artery pulsates, that is, alternately dilates and contracts, is not only proved by the finger, but by the eye; and therefore Dr. Parry and Magendie are incorrect in affirming that the pulse is distinguished only when pressure is made, the act of which diminishes the calibre of the artery, and tends to retard the course of the blood. The arteries always contain this fluid, and receive an additional supply at every contraction of the heart; but we have no direct evidence to prove that the pulsations of the heart and those of the extreme arteries are *synchronous*. It may not be possible to detect any difference, so rapid is the circulation, and so continued is the impulse; but upon reflection, it will be found impossible for the contraction of an extreme artery to take place at the same instant as the contraction of the heart, unless the former results from a previous contraction of the latter, the same blood not causing both heart and artery to beat at the same period. Every contraction of the heart is succeeded by dilatation of an artery, and by the time, or perhaps at the instant this dilatation occurs, the heart has acquired another supply, and becomes itself dilated. Here are *synchronous* beats, or, at least, a concurrence

of events; yet this is not what physiologists in general mean by the true synchronous. There is a continued systole and diastole of the whole arterial system, the circulation decreasing somewhat in force, if not in velocity, as it reaches the most remote vessels, and capable of exciting them to act without nerves; and the circumstance of their being independent of the nervous system, may arise, in some respects, from this circumstance. It is further evident that no impulse can be given by the force of the heart's action to an artery which, after being tied, receives blood only through anastomosing vessels, although it is evident they receive a larger share of influence in this instance; and therefore other means than what may be ascribed to the heart exclusively are necessary to carry on the circulation.

Ossification of arteries is adduced as a proof against their muscularity, in consequence of its not causing any particular impediment to the circulation; but this is scarcely worth observation, when we know that the same disease happens to the heart itself, without producing very great derangement in the sanguiferous system. The arteries may be partially deprived of their contractile power by ossification; but nature in such a case accommodates herself to the change, and gives additional impelling force to the heart; and, on the contrary, if this organ be the part affected, an additional power is given to the arteries. Nature is always ready to make up for a deficiency; and yet if the disease existed to a very great extent, either in the heart or in the arteries, it would cause fatal symptoms. Whenever the heart is the seat of such a disease, the pulse at the wrist is generally found to be irregular, cord-like, and weak; there are also strong palpitations, cold perspirations, occasional difficulty of breathing, besides other symptoms of general disorder of the system.

Mr. J. Hunter has said that the heart cannot be an essential organ, as many animals which have an uninterrupted circulation are destitute of it. I conceive that comparative anatomy is very apt to cause erroneous conclusions; and although it may not be the nature of some animals to require a heart in the sanguiferous system, it is evident that without this organ no creature in the higher scale of existence could exist. Preternatural pulsation in arteries is, as Laennec affirms, the most certain test that the arteries have an action of their own, independent of the heart; and Dr. Johnson says, "when any one will show us a pulsation in an artery where there is no corresponding ventricular contraction, then, and not till then, will we believe that the arteries can pulsate independently of any impulse from the heart." To reconcile these opinions is difficult; but it is most likely that preternatural pulsation never existed but with some disease of the arteries. That arteries have a contractile power is further proved by their being entirely emptied of blood after death. It has, however, been considered absurd to suppose this an effect of contractility, when the right ventricle and pulmonary arteries, which have still greater contractile power, are entirely full. Mr. Hunter has shown that the smaller arteries contract more on this occasion than the larger; and although it has been demonstrated by experiment that the lungs have no power over the arteries, some persons still persist in ascribing this vacuum to the lungs acting as a suction-pump to the arterial blood.

It is the opinion of most pathologists, that, in cases of inflammation, there is always increased action; that is, greater velocity and impetus in the circulation, and greater rapidity in the beats of an artery, than are necessary to the health of the part affected; but, after taking into consideration the nature of the arterial system, including the capillary vessels, and the state of the circulation, both in health and in inflammation, it will be found that such an inference is very objectionable.

To the capillaries belong two particular powers or properties—one of a contracting, the other of a dilating character; and the question is, what is the state of those powers in the time of inflammation? That an equilibrium can be kept up between them, in disease as well as in health, is certain, and there is no doubt that the former may be greatly weakened; but whether we are, in this case, to expect an increased accumulation, weight, or momentum of blood, is a point upon which many differ. But in commenting upon this

subject, it is necessary to be aware that an accumulation may exist without the vessels being increased in action at the same time, and that whenever the blood is increased in velocity, so as to excite inflammation, the vessels which previously contained colourless, become distended with red blood. It is evident, however, that all augmented supplies of blood must first be furnished by the heart; the small arteries cannot derive it from any other source; and it is very doubtful if, during inflammation, they have any power to attract any quantity from those vessels which do not partake of the disease, and which, in health, contain more than themselves. Increase of tonicity, or contractile power, would indicate increase of action in the circulation, and any loss of that power must necessarily be followed by a comparatively greater tendency to dilatation, and consequently a weakened or passive condition of the artery; in which state, in contradistinction to the former, we look for a larger proportion of blood being collected in the disordered vessels. When an equilibrium, therefore, is not preserved between these two powers, disorder or disease must inevitably ensue; and it is from these opposite states, for they cause an essential difference in the circulation, that we may derive much information, and be able to form a more favourable diagnosis of the nature of inflammation.

Increased velocity and increased momentum have very different significations; the former exists when there is quicker motion in the blood, and the latter is seldom found but when the contractility of the vessels is lessened, and the calibre increased. If there be by any means a greater portion of blood sent to a part than is natural, and is still pressed on without interruption, we conclude that the powers of the vessels are augmented in proportion to effect that object.

Here is no loss either of tonicity or elasticity; in the meantime it is very doubtful whether the heart can propel an unusual quantity of its fluid to one part more than to another.

Dr. Parry observes, that "the phenomena of inflammation are always increased momentum, or a diminished velocity with increased quantity; an increased velocity with increased quantity; an increased velocity with the same quantity; and lastly, an equal velocity with increased quantity." But he considers the proximate cause of inflammation in general to be an increased momentum of blood; and, as regards the power of the heart, he believes it capable of carrying on the circulation independently of any assistance from the arteries; which would lead us to infer that no such powers as those mentioned belong to the arterial system.

The cause of any increased action in the minute arteries may be either in the vessels themselves or in the heart. Conceiving the latter to be affected, as in fever, there is an acceleration of the blood's motion, which, if unattended by a proportionable active state of the vessels, is likely to produce either inflammation or congestion. In the time of fever, we have no evidence to prove (although the diastole and systole of the heart are more frequent) that the blood is invariably propelled with greater force; and that there should be a quantity sent from the heart at each contraction equal to what there would be in health, is very doubtful. As the velocity is increased, the momentum is, I conceive, generally or always diminished, and *vice versâ*. Dr. Cullen says, "the phenomena of inflammation all prove that there is an increased impetus of the blood in the part affected; and as, at the same time, the action of the heart is not always evidently increased, there is reason to presume that the increased impetus of the blood in the particular part is owing essentially to the increased action of the vessels of that part itself." We here find power given to the vessels; and it would be unreasonable to suppose that tubes so distant from the heart, so tortuously and intricately distributed, were merely passive and inert; and whenever the action of a vessel becomes increased, we reasonably calculate upon an increased velocity in the motion of the blood: one cannot exist without the other; but in this case there is no more than an ordinary supply of blood, and perhaps not so much as usual, sent to the part, and the calibre of the vessels, owing to their action being increased, is generally less than in health.

It has been proved by experiment, that when the blood circulates with unusual velocity (a circumstance easily known by the frequency of the pulse),

the vessels become paler and smaller; but, with an increased momentum of blood, they would be more charged, and consequently redder and larger; which implies that inflammation does not depend on an increased velocity, but on an increased quantity, and a diminished action in the vessels. The application of stimuli to an artery produces contraction, which may or may not be followed by exhaustion, inflammation, and a loss of tonicity. A preternatural contraction of certain arteries, be it occasioned by what it may, is a very common cause of inflammation; yet it does not follow that when this disease is actually developed — when we discover redness, swelling, pain, and extreme sensibility— that the vessels are in a preternaturally contracted state. It is further to be supposed that no contraction of arteries, whatever the cause may be, is of a spasmodic nature; a collapsed or impervious state of them, however, seldom continues any great length of time; the proper functions of nutrition being disordered, the textures lose their tone and power of resistance, and become exposed to the impulse of the blood behind. Some suppose an increased action is established in the vessels leading to the diseased parts, to relieve the morbid condition of that part; and supposing them to be so affected, it cannot be absurd to consider that some undue influence is communicated to them by means of the nervous intercourse subsisting between them and the disease; and I very much doubt if any such action is the effect of any primary design of nature to restore the part affected to health. When constitutional irritation ensues, the heart sympathises, becomes more frequent in its action, and the blood is sent with greater force through the whole system; and, conceiving that the blood could not be distributed through the body independently of any power of, or assistance from, the arteries, it is to be concluded that any effort to restore a diseased part, remote from the heart, must be attributed, in a great measure, to the small arteries.

The sanguiferous vessels are so constructed as to be able to accommodate themselves either to a large or a small proportion of blood. In the former instance, their diameter being increased, may terminate, if too long continued, in their debility; in the latter case, there is a comparatively small calibre, which, whether owing to a deficiency of blood, or any other cause, is no proof whatever of an actual loss of elasticity, or at least capability in the artery to dilate. The circulation in this state is usually more rapid, as is discovered by the pulse, which in such a case we never find full. In an unusually dilated vessel, a greater quantity of blood, and generally a loss of tonicity, are found; and this is the invariable condition of all passive, if not of acute inflammations; yet the dilatation may exist without any such disease being present, as may also an increased velocity. The throbbing experienced about an inflamed part, and so evident in that circumscribed tumor called whitloe, is a mere shock communicated to the nerves by the blood which is propelled against the obstructed vessels,—a compressed state of the nerves by effusion of serum causing greater pain than would otherwise occur. I do not conceive that the vessels preceding those that are inflamed need in consequence suffer from increased action, although it may be the case when the heart and arteries become affected. Nor is the pulsation any proof of increase in the momentum and velocity of blood in the diseased vessels. Added to this, the sensation is confined more particularly to that side of the inflammation nearest the heart, and the smaller the vessels, and the fewer the nerves, the less perceptible is this sensation, which is at all times synchronous with the beats of the heart, becoming more severe upon those beats being increased in force and frequency, which leads us to infer that it does not depend exclusively upon a preternatural action in the arteries behind. The sensation is also greatly influenced by the effort made to overcome the resistance offered by the congested vessels, and may hence be supposed to arise, in some measure, from the obstruction given to the due course of blood through the inflamed part, from a preternatural sensibility of the nerves of the inflamed part, and from an increased action of the heart and of the arteries. When depending upon the heart and arteries, the pulsation is evident to the bystander on application of the finger; when not, it is evident only to the afflicted person.

OBSERVATIONS

ON THE

CURE OF WOUNDS WITHOUT INFLAMMATION *.

By J. Macartney, M.D. F.R.S.

Professor of Anatomy and Surgery in the University of Dublin.

For above thirty years I have been in the habit of teaching that inflammation, so far from being necessary for the generation of tissues, retards that process when moderate, and prevents it when existing to a high degree.

This opinion I formed as the result of numerous observations and experiments, made on fishes and other of the lower animals, in which I found that even the most considerable solution of continuity was promptly remedied without the presence of any symptoms of inflammation, and that such symptoms never shewed themselves except where there were parts removed to be replaced.

My attention having been thus awakened, I was for some time in search of the best means of diminishing, or preventing, the development of inflammation; and the conclusion I arrived at was, that if the parts susceptible of being inflamed could be put in a condition of feeling only agreeable sensations, inflammation would not ensue, or, if present, would be soon dissipated.

It may be presumed that human beings, and animals of the higher orders, have the power of reproducing their tissues in a high degree—in fact, in almost as high a degree as the lower animals —if the parts be only affected with agreeable sensations. Daily experience tends to prove this. Do not emollient fomentations produce their good effects by soothing (*flattant*) the part affected? And do we not see the comfortable feeling experienced by the patient when his wounds are gently dressed and cleansed, and all bandages removed which hurt him by their pressure? Yet these views are by no means generally adopted: there are even practitioners who, far from agreeing in them, constantly employ local irritants, without reflecting that by these means they oppose the salutary operation of nature, the sole agent of every cure.

The most suitable mode of putting a wound in a state proper for cicatrization, is by enjoining repose, abstaining carefully from all sorts of irritation, dispensing with every kind of compress or bandage, unless there be absolute necessity for it: finally, to place it in such a position as that the blood and other humors, obeying the laws of gravity, may not rest on the parts affected.

There is no topical application better suited to our purpose than pure water, either in its liquid state or in the form of steam. We never employ any other. As to the temperature, it is to be regulated by the discretion of the surgeon, having regard to the nature of the injury and the sensibility of the parts. The steam I use is obtained by a very simple apparatus—a tin vessel opening funnel-wise, and thus at once diffusing the vapour and cooling it. A spirit-lamp sets it boiling; the steam is then received in a large tube of woollen stuff, kept in shape by a number of circles of bamboo. By regulating the lamp the temperature of the steam may be brought to any required degree.

We are thus enabled to apply the steam to the affected part. Another method is by laying on a soft pledget of lint, or cotton, previously steeped in water; and over this, in order to prevent suppuration, a piece of oiled silk. With this precaution the dressings will not have to be changed above three or four times in the twenty-four hours.

Much care and attention is requisite to adapt the temperature of the water to the purposes of nature. Sometimes it should be warm; at other times it ought to be cold. But, as a general rule, I should say that the most favourable temperature, or that best fitted for preventing inflammation, is the one which mitigates the pain the best. Thus, steam of a moderate degree of heat produces almost instant relief from pain, in the case of lacerated wounds, or where bones or ligaments are contused; but the more sensible tissues, which are more vascular, and more disposed of themselves to evolve heat, require a temperature absolutely cold.

By merely attending to the sensations of the parts injured, and abstaining from irritants, it is proved both by my own experience and that of surgeons

* Mémoires de l'Acad. Royale de Médecine, tome v. 1836. *Just published.*

who have followed the same course, that even the severest wounds are cured by repose alone. We also find that the *plastic force*, that is to say, the power of regenerating tissues, is far superior to what it is commonly supposed to be. I must be understood all along as supposing the constitution of the patient not tainted with congenital or acquired disease, such as scrofula, syphilis, or the like. With these exceptions, I have no hesitation in saying that in every instance we may cure, without pain, suppuration, or fever, penetrating wounds of the joints, wounds from fire-arms, with comminutive fracture of bones, and numerous other accidents equally severe.

Under the common mode of treatment the lips of a wound become tumid, diverge from each other, and are covered with granulations. When inflammation is prevented, on the other hand, they approach one another without any swelling; and so tenacious is nature of this approach, that it would require even a considerable mechanical force to prevent it. Thus the wound is soon obliterated; but re-union does not take place by any deposition of plastic lymph, as is the case in what is usually called union by the first intention. This formation of lymph is doubtless the effect of inflammation. In short, when no inflammation interferes, the margins of the wound gradually unite, and become combined; and what induces me to believe that there is no intermediate tissue is, that the cicatrix, under such circumstances, is much smaller than ordinary, and more uniformly of the colour of the surrounding parts: finally, also, it is more elastic and more natural.

It were superfluous to dwell upon all the consequences and advantages arising from a theory so simple, and a process so beneficial. The learned body to which I have the honour of addressing these remarks will readily supply what may be defective in them.

[The preceding paper, we presume, was presented to the Academy in acknowledgment of the honour, recently conferred on the author, of being elected a corresponding member.—ED GAZ.]

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri: potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

LOSSES OF LIFE IN THE MINES.

THE extreme reluctance with which any measures, however essential, having for their object the protection of life, are adopted by our Government, must be allowed to be sufficiently extraordinary. If the fact were not repeatedly pressed upon our notice, we could scarcely believe it: foreigners cannot comprehend it; they see no provision made by our legislature for interfering, particularly in civil arrangements, where the life of the subject is manifestly threatened: when the mischief is done, indeed, investigation takes place, and probably a forfeit in God's name—a *deodand*—is imposed on the brute animal, the senseless machinery, or the goods and chattels of the party through whom the fatality has occurred. But even this is omitted, unless culpability, within the meaning of the statute, attaches to the party. If a hundred lives be lost at a time, in pursuing some reckless system of employing human labour, a coroner's jury may probably return a verdict of "accidental death," and there the matter rests till the next catastrophe of the like kind take place, when a similar inquiry, with a similar result, is enacted—nothing meantime having been done to avert the recurrence of the evil.

The late explosion at Wallsend colliery was of this nature; *one hundred and one* lives of men and boys were lost in a moment; and not many years had passed previously when above fifty individuals perished in the same manner: it was all set down to *accident*, and so

it will be again when the next destruction happens.

When noticing, not long since, the Wallsend calamity just mentioned, it struck us that there was much blame to be attached to those in power who took no thought of passing events of this kind, but permitted them to recur again and again with all their lamentable circumstances and consequences, nothing whatever being interposed in the shape of a preventive. Tardily was the formation of the Committee to inquire into accidents in mines pressed on our legislatorial authorities; and sorry are we to find that that body have terminated their labours without proposing any definite plan to obviate the mischiefs of which they obtained such ample cognizance. They recommend, indeed, that the public be fully apprized of the nature of the case; and they *hope* much from the diffusion of the information they have gathered: but as to pointing out any positive or decided step that ought to be taken, —nothing whatever has been done.

What appeared to us, in our late consideration of the matter, as most likely to be beneficial, was the appointment of a number of inspectors—a higher order of police—men of intelligence and activity, whose special duty it would be to prevent, to the utmost in their power, the occurrence of those accidents. We have inspectors and overseers in various other departments of the body politic: prisons, lunatic asylums, factories, &c. have their commissioners or visitors, authorised to see that no detriment take place in these establishments. Why not extend the system to the inspection of mines and collieries, those fruitful sources of fatal mischief? We think we can gather from the tone of the Committee that they deem a measure of the kind advisable, although they venture not explicitly to say so: they let "I dare not," wait upon "I would," and seem to set their chief hope, their "most sanguine expectation," on the progress of public opinion. We cannot approve of these half measures; they may be more practicable, no doubt, than those we advocate, but they are chiefly practicable because they propose to do but little.

Let us see what is the emergency that calls for a new system of relief, and then we shall be the better able to judge whether the one suggested, or rather hinted at, by the Parliamentary Committee be adequate to the object proposed.

Of all the employments in which large bodies of men are occupied—with the exception, perhaps, of actual warfare—there is none to compare with Mining. Danger is always at hand; destruction and death are frequently present. The Parliamentary inquirers, it would seem, are not ignorant of this.

"Your Committee have had ample opportunity of multiplying proofs of the calamities which have occurred in the mines of this kingdem, by sudden explosions of fire-damps, foul air, or sulphur; all which terms are locally applied to carburetted-hydrogen gas, so copiously evolved in many of those mines. Few collieries are entirely free from fire-damp, but *in many the quantity emitted is so large that, in spite of skill and unremitting attention, the risk is constant and imminent*."—Report, Accidents in Mines, p. iii.

In proof of this assertion, the Committee insert in their Report all the coroners' returns they could procure, of inquests held in the mining districts during the last twenty-five years. The sum total is appalling. In the collieries along the rivers Tyne and Wear alone, the number of lives lost during the period just mentioned is 1125: in the other mining counties, exclusive of Durham and Northumberland, the incomplete, but, so far as they go, authentic records,

state the number at 954; giving, altogether, about 2070 as the number of those who perished by various *accidents* in the labour of the mines during twenty-five years! And this the Committee believe to be "vastly short of the actual number" of the victims.

We confess we are disappointed in the practical deductions of the authors of the Report; we doubt the efficiency of what they suggest, and we are disposed to think that their proposed measures cannot lead to much good. They state it to be their impression that "great benefit might be fairly and sanguinely anticipated from men of known ability being *encouraged* to visit the mines, whether in the character of distinguished chemists, mechanists, or philanthropists." "They are assured," they say, "that these visits would be received *with pleasure* by the mine-owners, and that every assistance in the way of experimenting would be promptly afforded." To us all this sounds flat and trumpery. Does it not almost border on the ridiculous to find legislators suggesting pleasure visits, and experimenting tours, to be *encouraged* by the countenance of government? Is this a way in which to meet the emergency? Is it thus an occupation which sweeps away hundreds of lives annually is to be regulated? Where are those men of known ability, distinguished chemists and mechanists, who are expected to play the *dilettanti*, and every now and then take a trip, for the sake of experiment, to the Wallsend colliery, and dive into the Bensham seam? We know of none such; and if the Committee think that an affair of this kind may safely be left to the voluntary services of amateur men of science, we can only warn them that they reckon without their host, and rest their sanguine expectations upon men of straw.

We repeat, that functions of the nature of those pointed out by the Committee, can only be safely calculated upon when they are performed as *duties*. Let the scientific and philanthropic visitors be endowed with official powers—let them be authorized to investigate frequently, and at what times they think fit, the state of the mines, with reference to the risk of fire and choke damp—let nothing depend upon mere encouragement and the pleasure of the mine-owners, and we answer for it, fewer accidents will be heard of — fewer will take place. Vigorous measures, in short, ought to be adopted. A heavy responsibility ought to be legally attached to the conduct of employers who commit to mere children the charge of trap-doors of vital consequence to the safety of the workmen. Only think of putting, in this way, into the hands of a child of 8 or 10 years old, the lives of hundreds of operatives; yet such is the constant practice in some collieries—persisted in even after the most woeful and repeated experience of the terrible effects that may result from it. There is no accounting for this sort of recklessness in defiance of common discretion; it amounts to infatuation.

There are three points in the Report which deserve a more than ordinary attention. These are the observations—1, on the system of ventilation followed in the mines, and the means suggested by intelligent witnesses for improving it; 2, on the use of the safety-lamp, and the consideration of the means by which it may be rendered perfectly secure; and, 3, the advantage of having exact maps and plans of the workings, pointing out also the position of adjacent abandoned mines, which may have become reservoirs of gas or of water.

The second point is the one in which we suspect the reader will take most interest. In their introduction of the

subject the Committee use these words—"The invention claimed by the late Sir Humphry Davy, on principles demonstrated by that able philosopher, may be considered as having essentially served the mining interests of this kingdom, and through them contributed largely to the sources of national as well as individual wealth. Many invaluable seams of coal never could have been worked without the aid of such an instrument, and its long use throughout an extensive district, with the comparatively limited number of accidents, proves its claim to be considered, under ordinary circumstances, a safety-lamp."

In connexion with this high and well-merited eulogium, we are tempted to lay before the reader "a striking fact," as mentioned by the reporters:—

"One striking fact requires to be particularly pointed out. If the year 1816 is assumed as the period when Sir H. Davy's lamp came into use, a term of eighteen years since 1816, and a similar term prior to 1816 being taken, it will be seen that in the eighteen years previous to the introduction of the lamp 447 persons lost their lives in the counties of Durham and Northumberland, whilst in the latter term of eighteen years the fatal accidents amounted to 538. To account for this increase, it may be sufficient to observe, that the quantity of coal raised in the said counties has greatly increased; seams of coal so fiery as to have lain unwrought, have been approached and worked by the aid of the safety-lamp. Many dangerous mines were successfully carried on, though in a most inflammable state, and without injury to the general health of the people employed in them. Add to this, the idea entertained, that on the introduction of that lamp, the necessity for former precautions and vigilance in great measure ceased."—*Report*, p. v.

With this quotation we discontinue our remarks for the present; for we find we must postpone our further observations on the subject till another opportunity.

CHAIR OF SURGERY IN EDINBURGH.

Sir Charles Bell has been unanimously elected to the professorship of surgery in Edinburgh, rendered vacant by the death of Dr. Turner; and we understand that he has accepted the chair which has been offered him in so gratifying a manner. That the electors have made a selection which reflects honour on their discernment, will be doubted by none, except perhaps the unsuccessful aspirants, and we believe that most even of them will feel that there is no dishonour in giving place to one of their brethren so justly distinguished.

As a lecturer Sir Charles Bell has long been pre-eminent, and he has consistently through life insisted on the great importance and honourable nature of the duties which devolve upon the medical teacher. Circumstances had latterly in some degree removed him from the sphere of his usefulness in this respect; and convinced as we are, from many of his recorded sentiments, that the lecture-room must ever be the scene of his happiest exertions, we rejoice for his own sake that an opportunity is again presented him, and under such flattering auspices, of resuming his useful and honourable calling in the field of his early labours.

Sir Charles Bell will next session lecture in Edinburgh, and ere then will of course have vacated his place among us; but we are sure that he will carry with him to the northern metropolis the respect and good wishes of all his professional brethren here. His departure will create vacancies in the offices of surgeon, and probably of assistant-surgeon, at Middlesex Hospital, and also in the Council of the College in Lincoln's Inn Fields.

As might be expected where there were disappointed candidates, some

petty manœuvring took place prior to the election, and it appears that some letters disparaging to Sir Charles were industriously circulated. We shall not stop to inquire into their origin; but it is gratifying to us to observe that one of the electors, in answer to these pasquinades, read various extracts from the MEDICAL GAZETTE, to prove the estimation in which Sir Charles Bell was held as a man of science, and we are pleased to find our humble testimony to his merits converted to so honourable a use.

Since the above was written, we have seen in the *Courier* some very absurd remarks on this subject, evidently supplied by some injudicious friend of Mr. Liston. The public are therein given to understand, that the Chair of Surgery was in the first instance offered to that gentleman, by whom it was declined; and the *Courier* is pleased further to inform us, that Mr. Liston will not give up his prospects in London "for any of the medical chairs in Edinburgh." We feel as much assured of this as the *Courier* can be. As to the rest, to suppose that Mr. Liston, notwithstanding his sudden journey to Edinburgh on the death of Dr. Turner, ever had it in his power to obtain the professorship just conferred on Sir Charles Bell, is—a mistake. The real state of the question, as regards all parties, will be seen from the speech of the Lord Provost, which we subjoin *, and which, from the unquestionable nature of the authority, renders any farther remarks of ours altogether superfluous.
